Acerca de este libro

Esta es una copia digital de un libro que, durante generaciones, se ha conservado en las estanterías de una biblioteca, hasta que Google ha decidido escanearlo como parte de un proyecto que pretende que sea posible descubrir en línea libros de todo el mundo.

Ha sobrevivido tantos años como para que los derechos de autor hayan expirado y el libro pase a ser de dominio público. El que un libro sea de dominio público significa que nunca ha estado protegido por derechos de autor, o bien que el período legal de estos derechos ya ha expirado. Es posible que una misma obra sea de dominio público en unos países y, sin embargo, no lo sea en otros. Los libros de dominio público son nuestras puertas hacia el pasado, suponen un patrimonio histórico, cultural y de conocimientos que, a menudo, resulta difícil de descubrir.

Todas las anotaciones, marcas y otras señales en los márgenes que estén presentes en el volumen original aparecerán también en este archivo como testimonio del largo viaje que el libro ha recorrido desde el editor hasta la biblioteca y, finalmente, hasta usted.

Normas de uso

Google se enorgullece de poder colaborar con distintas bibliotecas para digitalizar los materiales de dominio público a fin de hacerlos accesibles a todo el mundo. Los libros de dominio público son patrimonio de todos, nosotros somos sus humildes guardianes. No obstante, se trata de un trabajo caro. Por este motivo, y para poder ofrecer este recurso, hemos tomado medidas para evitar que se produzca un abuso por parte de terceros con fines comerciales, y hemos incluido restricciones técnicas sobre las solicitudes automatizadas.

Asimismo, le pedimos que:

+ *Haga un uso exclusivamente no comercial de estos archivos* Hemos diseñado la Búsqueda de libros de Google para el uso de particulares; como tal, le pedimos que utilice estos archivos con fines personales, y no comerciales.

+ *No envíe solicitudes automatizadas* Por favor, no envíe solicitudes automatizadas de ningún tipo al sistema de Google. Si está llevando a cabo una investigación sobre traducción automática, reconocimiento óptico de caracteres u otros campos para los que resulte útil disfrutar de acceso a una gran cantidad de texto, por favor, envíenos un mensaje. Fomentamos el uso de materiales de dominio público con estos propósitos y seguro que podremos ayudarle.

+ *Conserve la atribución* La filigrana de Google que verá en todos los archivos es fundamental para informar a los usuarios sobre este proyecto y ayudarles a encontrar materiales adicionales en la Búsqueda de libros de Google. Por favor, no la elimine.

+ *Manténgase siempre dentro de la legalidad* Sea cual sea el uso que haga de estos materiales, recuerde que es responsable de asegurarse de que todo lo que hace es legal. No dé por sentado que, por el hecho de que una obra se considere de dominio público para los usuarios de los Estados Unidos, lo será también para los usuarios de otros países. La legislación sobre derechos de autor varía de un país a otro, y no podemos facilitar información sobre si está permitido un uso específico de algún libro. Por favor, no suponga que la aparición de un libro en nuestro programa significa que se puede utilizar de igual manera en todo el mundo. La responsabilidad ante la infracción de los derechos de autor puede ser muy grave.

Acerca de la Búsqueda de libros de Google

El objetivo de Google consiste en organizar información procedente de todo el mundo y hacerla accesible y útil de forma universal. El programa de Búsqueda de libros de Google ayuda a los lectores a descubrir los libros de todo el mundo a la vez que ayuda a autores y editores a llegar a nuevas audiencias. Podrá realizar búsquedas en el texto completo de este libro en la web, en la página `http://books.google.com`

This is a digital copy of a book that was preserved for generations on library shelves before it was carefully scanned by Google as part of a project to make the world's books discoverable online.

It has survived long enough for the copyright to expire and the book to enter the public domain. A public domain book is one that was never subject to copyright or whose legal copyright term has expired. Whether a book is in the public domain may vary country to country. Public domain books are our gateways to the past, representing a wealth of history, culture and knowledge that's often difficult to discover.

Marks, notations and other marginalia present in the original volume will appear in this file - a reminder of this book's long journey from the publisher to a library and finally to you.

Usage guidelines

Google is proud to partner with libraries to digitize public domain materials and make them widely accessible. Public domain books belong to the public and we are merely their custodians. Nevertheless, this work is expensive, so in order to keep providing this resource, we have taken steps to prevent abuse by commercial parties, including placing technical restrictions on automated querying.

We also ask that you:

+ *Make non-commercial use of the files* We designed Google Book Search for use by individuals, and we request that you use these files for personal, non-commercial purposes.

+ *Refrain from automated querying* Do not send automated queries of any sort to Google's system: If you are conducting research on machine translation, optical character recognition or other areas where access to a large amount of text is helpful, please contact us. We encourage the use of public domain materials for these purposes and may be able to help.

+ *Maintain attribution* The Google "watermark" you see on each file is essential for informing people about this project and helping them find additional materials through Google Book Search. Please do not remove it.

+ *Keep it legal* Whatever your use, remember that you are responsible for ensuring that what you are doing is legal. Do not assume that just because we believe a book is in the public domain for users in the United States, that the work is also in the public domain for users in other countries. Whether a book is still in copyright varies from country to country, and we can't offer guidance on whether any specific use of any specific book is allowed. Please do not assume that a book's appearance in Google Book Search means it can be used in any manner anywhere in the world. Copyright infringement liability can be quite severe.

About Google Book Search

Google's mission is to organize the world's information and to make it universally accessible and useful. Google Book Search helps readers discover the world's books while helping authors and publishers reach new audiences. You can search through the full text of this book on the web at `http://books.google.com/`

SUPPLEMENT TO "THE ELECTRICAL ENGINEER," JUNE 26, 1896.

THE

ELECTRICAL ENGINEER.

A WEEKLY JOURNAL OF ELECTRICAL ENGINEERING,

WITH WHICH IS INCORPORATED

"ELECTRIC LIGHT."

VOL. XVII. (NEW SERIES.)

FROM JANUARY 3, 1896, TO JUNE 26, 1896.

LONDON:

Printed and Published for the Proprieto by BIGGS & Co., at "THE ELECTRICAL ENGINEER" Offices, 139-140, Salisbury-court Fleet-street, E.C.

1896.

Digitized by Google

INDEX TO VOL. XVII. (New Series.)

NOTE.—General Articles, Correspondence, and Companies' Meetings are indicated by heavier type (thus, 290) than the Notes and Business Notes, references to which are shown by light type (thus, 290).

A.

Aberdeen Electricity Accounts, 181
Absolute Measurement of Resistance, 703
Accidents, 29, 85, 114, 141, 193, 209, 219, 275, 281, 332, 478, 533, 561, 589, 590, 592, 617, 701

Accumulators:
Applications of, 33
Blot, The, 116
Carbon-Zinc, A New, 561
and Electro-Chemistry, 225
Epstein, for Cycles, 362
Faure Patents, Results of Expiry of, 113
Jacques, The, 339, 591
Lessing Battery, 242
Milver, The, 58
Problem for, 282, 309
Tudor, The, 473

Acetylene, 57, 172, 253, 312, 337, 393, 445, 449, 479, 674
Acetylene Motor, An, 701
Ackroyd and Knowles, Messrs., Permeability to Rontgen Rays, 329
Aerial Graphoscope, The, 281
Agencies, 53, 81
Allen, A. H., The Mechanical Equivalent of Heat, 314
Alloys, Resistivity of, 702
Alternate-Current Dynamo-Electric Machines, J. Hopkinson and E. Wilson, 621
Alternate-Current Transformers, Dr. Fleming, 105, 133, 153, 180
Alternate-Current Working, Principles of, A. Hay, 690
Alternating-Current Motor, The Langdon-Davies, 702
Alternating-Current Stations and High-Voltage Lamps, H. W. Couzens, 652
Alternating *v.* Direct Currents, W. Baxter, 3
Alternating Systems, E. Scott, 423
Alternators, *see* DYNAMOS
Alternators, Parallelling of, R. Hammond, 296, 325
Aluminium, 1, 456, 510
Amazon Cable, The, 169, 450, 553, 594, 617
American Electric Trams, Letter to *Times* on, 618
American Fire Office Rules, 32, 115
American Institute of Electrical Engineers, 337, 684
American Invention for Preventing Railway Collisions, 86
American Motor League, 57
American National Electrical Exposition, 29, 645
American Notion on Exhaustion of Electric Fluid, 143
American Pacific Cable, 113, 337, 338, 506, 556, 619
American Safety Rules, Conference on, 58, 397
American Tramway Rules, 394
American Way (Electric Hearses), 58
Analysis of Transformer Curves, C. J. Huguet, 663
Apparatus for Providing a Steady Platform at Sea for Searchlights, etc., B. Tower, 477, 512
Appleyard, Mr., Adjustment of the Kelvin Bridge, 495
Appointments, 80, 113, 197, 275, 279, 281, 303, 309, 360, 426, 445, 471, 477, 529, 555, 583, 612, 617, 722
Appointments Vacant, 53, 81, 110, 139, 165, 218, 303, 335, 362, 390, 445, 474, 500, 556, 584, 586, 641, 668, 698
Arabian Thunderstorm, An (Effect of at Aden), 590
Arc Light, The, S. P. Thompson, 47, 71, 99, 129, 156
Arc, Resistance of, 367
Arcs, Three-Phase, 506
Are We Educating Too Many Electricians? H. Floy, 31
Argon, 88, 618
Armatures, Life of, 144
Armstrong, Dr., Nature of Chemical Change and the Conditions which Determine it, 438 463, 492, 519, 577, 607
Artificial Ice Floor for Skating 37
Association of County Councils in Scotland, 723
Atlas Aluminium Works, 721
Attenuating Toxines, 227, 533
Australian Difficulty, An (Coolgardie Electric Lighting), 673
Ayr Electricity Works, 5, 36
Ayrton, Prof., Magnetic Tester, 675, 704
Ayrton, Prof., Report on Berrenberg-Chaplin Vacuum Pump, 86

B.

Bacteria and the Alternating Current, 505
Baker, J. A., Letter to L.C.C. on Electric Traction for London Tramways, 713
Baltimore Electric Locomotive, 369
Barcelona Exhibition, 59
Barnard, A. S., Electricity Supply at 220 Volts, 652
Barr, J. M., S. Beeton, C. P. Taylor, Experimental Tests on the Influence of the Shape of the Applied Potential Difference Wave on the Iron Losses of Transformers, 551, 567
Batteries, Storage, *see* ACCUMULATORS
Bedford Accident, 592
Beeton, S., C. P. Taylor, J. M. Barr, Experimental Tests on the Influence of the Shape of the Applied Potential Difference Wave on the Iron Losses of Transformers, 551 567
Belgian Electrical Engineering Practice, A. Anstruther-Thomson and G. C. Allingham, 535
Bennett, A. R., The Telephone Question, 184, 204, 236
Berlin Exhibition, 477
Berrenberg Metallic Vacuum Pump, 37, 87
Beryllium, 477
Best Light, Prof. E. Thomson on, 198
Best Wishes for 1896 (Leading Article), 14
Bicycle, A Wonderful (Electric), 564
Bimetallic Wire, 312
Birmingham Electric Tramways, 407
Birmingham and Midland Institute, 58
Birmingham Town Council and Mechanical Traction, 81
Block Telegraph System, The, J. Pigg, 19
Blot Accumulator, The, 116
Board of Trade Regulations, 141, 206
Boilers at Electric Light Stations, 398, 406
Books Received, etc., 25, 53, 109, 197, 302, 305, 337, 393, 444, 506, 533, 617, 673, 697, 701
Bottle-Labelling Machine, 57
Brakes and Fenders, Use of, 480
Brighton Electricity Works, Extension of, 705
Brighton and Rottingdean Tramroad, 529
Brighton, To, in Twenty Minutes, 57
Brilliant Invention, A (Electric Overcoat), 421
Bristol Corporation Electricity Works Accounts, 271
British Aluminium Works at Foyers, 219, 456, 510, 673
British Association, 50, 337, 395
British Pacific Cable, 85, 309, 556, 589, 614, 619, 648, 678
Budapest Exhibition, 393, 422
Buenos Ayres Exhibition, 533
Burns, Unveiling of Centenary Statue by Lord Kelvin, 701
Business during 1895, 16, 43, 83, 81

C.

Cable Interruptions, 3, 57, 85, 113, 225, 309, 337, 365, 477, 589, 619
Cable-Laying on the Amazon River, A Siemens, 594
Cable-Laying Steamer, A New, 585
Cable Repairing, A Tropical Repair, 13
Cable Specifications and Tests, J. A. Jeckell, 656
Calcium Carbide, Manufacture, etc., of, 113, 617
Cambridge to Glasgow (Cambridge Public Orator's Latin Address), 673
Campbell, Mr., New Instruments for the Direct Measurement of the Frequency of Alternating or Pulsating Electric Currents, 610
Can an Electric Circuit be Opened without an Arc? A. J. Wurtz, 409
Carbide of Calcium, 113, 617
Carbide of Cerium, 281
Carbide of Manganese, Electrical Preparation of, 337
Carbide of Uranium, 281
Carbides of Yttrium and Thorium, Electrical Preparation of, 422
Carbide of Zirconium, 365
Carbon Contracts, 668
Carbon and Permeability, 562
Carbon Resistances, 476
Carbon-Zinc Accumulator, A New, 561
Cardew, Major, Report of Cheltenham Accident, 209
Carpenters' Hall Lectures, 225, 237, 264, 323
Catalogue of Scientific Literature, Proposed, 701

Catalogues, etc.:
Beauland, Perkin, and Co., 137; Bolling and Lowe, 24; Brown, Boveri, and Co., 585; Brush Electrical Engineering Company, 617; Chloride Electrical Storage Syndicate, 24, 54, 82; Dorman and Smith, 276; Electrical Company, 181, 334; Electrical Power Storage Company, 24, 113; General Electric Company, 39; Hunt, C. W., and Co., 645; Jackson, P. R., and Co., 220; Lithanode Company, 334; Osler, F. and C., 499, 556; Pittsburgh Reduction Company, 275; Salmony and Co., 191; Scott and Mountain, 82; Sunbeam Lamp Company, 445; Sunderland and Co., 445; Willcox and Co., 54

Caustic Soda and Bleach, Electrolytic Production of, 149
Central American Exhibition, 613, 585
Central-Station Problem, A, C. R. Van Trump, 436
Central-Station Working—Line and Station Expedients and Methods, E. B. Newcomb, 318
Central Supplies for Electric Lighting, etc., 113
Central Technical College Conversazione, 675, 677
Cerium Carbide, 281
Chapsal Brake, 143
Cheltenham Accident, 209, 275
Chemistry and the Arc, Prof. Dewar on, 450
Chemical Society, 114, 141, 438, 463, 492, 489, 519, 577, 617
Chesterfield and Midland Counties Institution of Engineers, 365, 388
Chicago Exhibition, 701
Chicago Tramways, Statistics of, 618
Chimney-Shaft Stability, 199
Choosing a Motor, 170
Chronographs in Gun Ballistics, 507
Church Lighting Extraordinary, 618
Cinematograph, The, 281, 421
City and Guilds of London Institute, Lectures, 34, 95, 146, 175, 201, 342, 426, 454, 482, 515, 566
City and Guilds of London Institute, Meetings, etc., 115, 181, 169, 171, 237, 225, 253, 450, 453, 589, 698
City and Guilds of London Institute, 1896 Examination Papers, 575, 603
City and South London Railway Bill, 275, 586, 674
Clarke's Coal-Cutting Machine, 285
Cleveland Institute of Mining Engineers, 472
Cleveland Message, Effect on American Electricity Companies' Business, 138
Cold Light, Production of, 367

THE

ELECTRICAL ENGINEER.

No. 1, Vol. XVII. LONDON, JANUARY 3, 1896. PRICE 3D.

NOTES.

Back to Electricity.—The Avenue de l'Opéra in Paris is to be again lighted by electricity instead of gas. In the early days of electric lighting the Jablochkoff candle was used for a time in the Avenue.

A New Year's Dinner.—On New Year's Eve a dinner was given by Mr. Robt. W. Paul, of 44, Hatton-garden, to all his employés. The dinner took place at the Holborn Restaurant, and a very pleasant evening was spent.

C.M.G.—In the list of the New Year honours occurs the name of Mr. Henry Charles Fischer, controller of the Central Telegraph Department of the General Post Office, who is made a Companion of the Order of St. Michael and St. George.

A New Use for Electric Tramways.—According to the *Street Railway Journal*, the Sioux City Electric Tramway Company have been running a car which carries no passengers, but is exclusively devoted to the display of advertisements.

The Electrical Standardising, Testing, and Training Institution.—Mr. James Swinburne will commence his usual course of lectures on "Dynamo and Transformer Construction" at this institution, Charing Cross-road, on Thursday, January 9.

Electricity in Dentistry.—Dr. M. G. Jenison, of Minneapolis, reports that electricity has been successfully employed by him in checking hemorrhage from the extraction of teeth. The current, he states, caused instant coagulation of the blood and gave relief where the usual remedies were without effect.

Electricity at Christmas.—It is noted that the Christmas tree at the University College Hospital, Gower-street, was this year illuminated by a number of little Edison-Swan lamps. There may not be quite so much sentiment about the electric light as with the time-honoured candle, but it is certainly much less dangerous.

Telegraphs in Turkey.—The authorities of Aleppo have petitioned the Central Government to lay a telegraphic line between Marash and Enderin. Several localities situated on the Turko-Persian frontier, in the district of Suleimanieh, are about to be connected by telegraph lines with each other and with the network of the empire.

High-Voltage Tramway Lines.—With the increase in the length of tramway systems in America comes the desire to raise the pressure above 500 volts. The *Street Railway Review*, in advocating this, says that, in view of past experience, it is not unreasonable to consider that 1,000 volts direct current might be used with safety on long trolley lines.

Aluminium.—It is stated that the Pittsburg Reduction Company are about to increase their producing capacity at Niagara Falls to a very important extent. A contract has just been concluded with the Cataract Construction Company whereby the Pittsburg Company's new plant, established at the Falls last year, will be doubled in capacity, making it the largest aluminium works in the world.

The Nile as a Motive Power.—According to the *Politischen Maschinen Constructeur*, the problem of using the Nile as a source of energy is being seriously considered in Egypt. If a reservoir is constructed at Assouan a fall of 15 metres (49ft.) would be available, and another fall of 5 metres (16½ft.) could be utilised in the neighbourhood of Cairo. The proposal is to set up at these places electric power distributing plant which would serve a series of cotton mills.

Indian Government Telephones.—The *Indian and Eastern Engineer* says that a much improved system of telephone apparatus will shortly be introduced into some of the Indian Government offices. The apparatus is of the type first exhibited at the late Chicago Exhibition, which does away with the necessity of ringing the bell to signify one's intention of making a communication. In the new apparatus it is claimed that it is only necessary to speak and the communication will be heard for a good space around the instrument at the other end.

The Turin Exhibition of 1898.—From *L'Elettricità* it appears that the committee entrusted with the organisation of the electrical section of the Turin Exhibition of 1898 has passed a resolution to the effect that as the electric industry in Italy has nothing to fear from comparison with foreign work, and, moreover, since being of scientific as well as manufacturing and mechanical interest, the province of an electrical exhibition is world-wide, the committee have determined that the electrical section of the exhibition should be open to all nations.

Telegraphs in Central Africa and China.—The telegraph line is now completed from Cape Town to Blantyre, and before Major Forbes leaves the Chartered Company's northern territory it will be laid to Tanganyika. Dr. Robert Laws has trained Atonga converts to become skilled signallers at Karonga, Koudowi, and Bandawe. On the Asiatic side, the direct route to China overland, through Mora and Burma, by Bhamo, is in working order, and it is reported from Calcutta that the traffic is steadily increasing, and that the route only needs to be tried more largely to lead the Chinamen signallers to do still better.

Trolley Patents in the States.—Judge Townsend, of the United States Circuit Court, has sustained the fundamental patent of Van Depoele on the trolley, and declared void a subsidiary patent applying to the rotating support on which the trolley arm swings. The decision will be appealed against, but the *Electric Railway Gazette* thinks that in the meantime its effect will be to direct greater attention to underground electric traction systems in the United States. If the decision is sustained, it practically gives the General Electric Company the right to manufacture and sell the under-running trolley as it is used on most American tramroads.

Genoa Tramways.—A paragraph has been going round the papers to the effect that the electric tramways in

Digitized by Google

Genoa had been stopped by the police authorities on account of danger to the public. The truth of the matter appears to be that there is in Genoa a very steep and long street, called the Via Assarotti, with a gradient of 7½ per cent., and on the tramline in this street two cars overran their brakes and killed a horse, upon which the authorities stopped temporarily the running on this line only. It is further stated that, so far from the tramways being unsatisfactory, it is intended to extend the system during the coming year right out to the suburb of San Francisco d'Albano.

Liverpool Engineering Society.—At the meeting of this society on January 8 a paper will be read by Mr. J. R. Fothergill, M.Inst.N.A., M.Inst.Mech.E., on "Combustion in Marine Boilers," and the president will present the West Premium to Mr. Wm. Rowland, Whit.Sch., for his paper entitled "Recent Improvements in Locomotive Design." The president will also announce that the Right Hon. the Earl of Derby, G.C.B., and Mr. W. H. Preece, M.I.C.E., C.B., F.R.S., vice-president of the Institution of Civil Engineers, have, upon the invitation of the council, agreed to become honorary members of the society. The annual dinner of the society will take place at the Adelphi Hotel, Liverpool, on January 29, 1896.

The Madras Electric Tramways.—Mr. F. R. Upcot, consulting engineer for railways, has officially inspected the section of the line recently completed between the Napier water pandal and Barber's bridge *vid* Chintadripettah and Triplicane. Mr. Upcot was accompanied by his deputy (Mr. Fowler), Mr. O'Shaughnessy, chief engineer, M.E.T., Mr. Gadsby, electrician and superintending engineer, Mr. Winter, electrical engineer, M.R.C., Mr. Salisbury, assistant secretary, and Mr. Whitmore Clarke. The trip on the car worked by the overhead system was not quite successful, there being some hitch owing to heavy rain and to an inadvertent omission in the equipment of the car, which is easily remediable. The consulting engineer declared the line fit for traffic.

Electric Elevator.—A unique electric elevator has been built for the Ottawa Canoe Club, Ottawa, Ont. The Ottawa River being subject to a great rise every spring, the boathouse, necessarily, is situated during the greater part of the year at a considerable elevation above water level. In order to minimise the difficulty hitherto experienced in transferring boats from the house to the water, or *vice versâ*, there has been erected a framed gangway, with skeleton car, elevated by means of an ordinary worm-geared hoisting drum. The motive power is obtained from a three-kilowatt 500-volt Edison motor. The motor is belted to a countershaft, which, in turn, is belted to the shaft carrying the worm, and the car is stopped automatically at the termination of its course either way.

Spain.—Steady progress, says *Industries and Iron*, continues to be made with the adoption of electric lighting in Spain. It has been decided to increase the capacity of the plant at the central station at Tolosa. A 60 years' concession has lately been granted for the establishment and the operation of a central station at Vera, a small town in the province of Almeria. Two new 45-h.p. steam dynamos are being added to the central station at Torrelavego (Santander province). Work is at present in hand on the establishment of a central station at Burriana in Castellon province. The plant, which is being supplied by Messrs. Levi and Kocherthaler, who are the Spanish agents of the Allgemeine Elektrictäts-Gesellschaft of Berlin, comprises a 100-h.p. steam-engine and a continuous-current dynamo. The distribution is on the overhead three-wire system.

The Telephone Monopoly.—The *City Press* says that the Telephone Company is always getting into hot water. One day it is the charge that gives rise to indignation on the part of subscribers. Another day the difficulty of getting attended to, and when attended to of being able to obtain connection is insisted upon. Now we have a would-be subscriber instancing the delay there is in inducing the company to place him on the telephone. He has been waiting, it seems, for six months, and still, to all appearances, he is no nearer being supplied that he was when the application was made. The delay there is in remedying the first-named shortcomings is understandable, but certainly it surpasses comprehension to realise the object the company has in being so blind to its own interests as to disregard orders to provide a receiver and the necessary connection. The rush of orders cannot be so great as to prevent each being attended to the moment it is received.

Electric Tanning.—Some interesting work on the subject of electric tanning is reported in the *Zeitschrift für Elektrochemie* by Herr Folsing. The writer states that he has worked out an electrical method of tanning, which he considers is suitable for both thin skins and heavy hides, and only requires from three to six days. The tanning pit contains 15,000 litres. Electrodes of nickelled copper are fixed to the walls of the pit, in which the hides are hung so that the current has to pass right through them. A current of 12 amperes with an E.M.F. of 12 volts is used. The colour of the leather is not quite satisfactory when commercial unpurified extract is used. The author lays stress on this, and he himself used an oak extract (with a little hemlock extract added) which is cleared and decolourised by a special electrolytic process. When this is used he finds that the colour is exceedingly good and bright. Light cowhides were found to require 72 hours, heavy cowhides five days, and heavy oxhides six days. The latter would require about a year by the old process.

The Kane-Pennington Motor.—The *Canadian Engineer* says that readers will be interested in knowing that the Mr. Pennington whose new motor it describes is the some gentleman who has been experimenting on machinery for navigating the air. "Though the application of the Kane-Pennington motor has been on machines travelling on land, the extraordinary power developed by the invention may actually lead to the accomplishment of what Mr. Pennington and so many other inventors have been vainly striving at—aerial navigation. The achievement will probably be as great a surprise to Mr. Pennington as to the rest of the world, but from tests reported in the *American Machinist* it really seems that the highest accomplishment of mechanical genius will soon be the gift of mankind. The principle of this new motor is so far a secret, and mechanical men, of all others with whom the writer has discussed the matter, have been most sceptical. Yet the tests made and the details given upon so good an authority, leave little doubt that the new motor is all that is claimed for it."

The Chicago Motocycle Race.—The American papers contain descriptions of Messrs. Morris and Salom's electric carriages which took the gold medal in the Chicago motocycle race. The largest of these appears to be built somewhat on the lines of what is called in America a "Surrey." The front wheels are the larger, and are driven by two Lundell motors of 1½ nominal horse-power capacity, each attached to the front axle and pinioned on the armature shafts, gearing directly into the driving gears attached to the wheels. The steering is done with the hind wheels. The energy is derived from batteries furnished by the Electric Storage Battery Company, of Philadelphia, and consist of four sets of 12 cells

Digitized by Google

each, having a normal capacity of 50 ampere-hours per cell. They are grouped in boxes and so arranged that they can quickly be pushed into place inside the body of the carriage, connection being automatically made with the controller. The maximum speed is stated to be 20 miles an hour on a good road, and the weight of the vehicle, complete with batteries, is 1,650lb. Messrs. Morris and Salom appear to be purists in the matter of language, since, despising such hybrids as "autocar," they boldly call their carriage an "electrobat."

The Telegraphic Communication with South Africa.—The Postal Telegraph authorities having given notice of "considerable delay to South Africa owing to the interruption of the Aden-Zanzibar cable," a representative of the Press Association made inquiries at the offices of the Eastern Telegraph Company, and was informed that the delay was caused by the breaking of the cable between Aden and Zanzibar, on the East Coast route, which is the direct telegraph route to South Africa. So far as was known, the interruption had occurred near to Zanzibar, but a repairing vessel had been despatched and it was anticipated that the usual communication would be speedily restored. So far as the informant knew, the delay was not due to any disturbance in the Transvaal itself. The interruption has thrown extra work on the West Coast route, where the arrangements at the best do not afford facilities for great expedition. The delay has thus, in some instances, been as much as 24 hours. Government messages, however, have come through as usual, they having precedence of all others. It is stated that the last two private messages which came through from South Africa were one which left Johannesburg at 3.30 p.m. on Monday, and another which left at 5.20 p.m. the same day, reaching the office in London at midnight.

The Electrophone.—A representative of *London* has interviewed Mr. H. J. Booth, of the Electrophone Company. Seated in an armchair in the company's Board-room at Pelican House, Gerrard-street, W., he heard the performances at four London theatres. He was, however, apparently much disappointed to find that the electrophone was not more striking to look at. "It is," he says, "very insignificant, and looks no more imposing than a small cigar-box with wires attached. Few people would understand its use even if they happened to see it in a theatre or public building." After a certain amount of music, the interviewer of course suggested that Mr. Edison was the inventor. "Oh, no," replied Mr. Booth. "Most people seem to think that we owe the electrophone to the ingenuity of Mr. Edison. As a matter of fact, it is the invention of a Servian and an Austrian, and Mr. Edison did not to my knowledge see it until he saw it in Paris." The electrophone is not confined to theatres, but is also laid on to several churches. The consent of the deacons of the City Temple has, however, not yet been secured. Mr. Booth hopes soon to place instruments in the two Houses of Parliament in order to enable constituents in the provinces to listen to debates in which they are particularly interested, but which they cannot otherwise hear without travelling to London. This opens up a pleasing prospect for the local member, who is usually much more eloquent in country than he is in the House.

Alternating v. Direct Currents.—In the New York *Electrical Engineer* Mr. W. Baxter continues his advocacy of the continuous current. "The only extensive application," he says, "of the alternating current at the present time is for incandescent lighting. A few arc lights are also operated by it, but for this purpose it is far inferior to the direct current. Anyone desiring to instal an arc lighting plant would not take the alternating system into consideration for a moment. Arc lamps of this type are only used where they are so far apart or so few in number as not to justify the expense of a separate circuit." Mr. Baxter thinks very little of the prospects of the multiphase motor, and says that European engineers are so much in favour of the alternating system because "with them incandescent lighting is about the only practical application of electricity. It is true that they use a few arc lights and stationary motors, and a sprinkling of electric railways, but the development on these lines dwindles into insignificance when compared to what we are doing on this side of the Atlantic. Very few, even among those engaged in electrical work, are aware of the fact that in New York City alone there are several thousand motors used for manufacturing and for operating elevators, while small fan and sewing-machine motors are as numerous as flies around a candy store." It is further urged that "one of the principal objections to the alternating current is the increased difficulty of transmission, and yet we transmit energy by this system, and at the receiving end convert it into a direct current so that we may be able to make use of it. Would it not be a wiser policy to rectify the current before transmission and thus save, either in cost of construction, wire, or in higher efficiency of transmission? If it would be wise to go that far, would it not be still wiser to go one step farther and replace the alternator with a direct-current generator and thus save the extra loss in transformation as well as in transmission? Obviously the correct answer to these questions is, that if the direct current can be successfully used at as high an E.M.F. as the alternating it would be the one best adapted to our requirements."

"The Overhead Trolley Must Go."—Under this alarming heading the *Electrical Journal*, of Chicago, quotes from one of its daily contemporaries as follows: "If there is anything above or below this mundane sphere which should serve as a check to the speed of trolley lines in the centre of Chicago, it was last night's storm. And if the distinguished ordinance makers and franchise givers have a grain of sense, they will at once begin to mend their evil ways. It was as much as an honest man's life was worth to be on the streets last night. Broken telephone and telegraph wires hung across trolley lines, turning the whole city into an electrocution chair. The heavy current of the trolley lines passed to every contacting wire, establishing a perfect and deadly circuit, which interrupted telephonic and telegraphic communication and endangered human life. These conditions are possible with every big storm. They should warn the Council against indulging in further generosity to street railway companies. If the danger last night was great, what will it be when President Wheeler's trolley lines are strung along Clark-street from the south to Washington-street? And when Mr. Yerkes hypnotises his aldermanic subjects into giving him an overhead trolley loop down town? While the extension of electric transit lines may be a means of increasing the revenues of aldermen, it is extra menace to human existence and should cease forthwith. The overhead trolley must go." Speaking of the trolley car, a very practical use has been found for it in Newark, N.J., where a contract has been made with a leading bakery to deliver smoking hot bread in the early hours of the morning to points within 14 miles of that city. This work was formerly done by 50 delivery wagons, but it has been found that time and money can be saved by the new arrangement. To Jersey City alone 18 of these wagons have formerly been despatched; hereafter a certain number of them only will be employed to make the local delivery to the grocers, the supply being had

Digitized by Google

from the trolley car on its arrival from Newark. The cars will be run at an hour of the night when they will be unobstructed and will not in any way interfere with the regular passenger service. The brewers are talking of utilising the trolley for similar purposes.

Germany and Austria.—The question of electric traction is at present receiving the consideration of the municipal authorities of Solingen. The four leading electrical engineering firms have each submitted plans for several projected lines. The municipal authorities of Coblenz have given their approval to a scheme for the construction of an electric tramway between the Rhine railway station in Coblenz and Ehrenbreitstein. It is also proposed to construct an electric tramway at Neumarkt, in Silesia, between the railway station and the town. A central electric lighting station has just been completed and put in operation at Gunsberg, a small town in Bavaria. The plant, which has been supplied by Messrs. Schuckert and Co., of Nuremberg, is driven by water power. A small steam-power plant has also been put in by way of reserve. Tenders are at present being invited for the electric lighting of the town of Brumath, in Alsace. It is proposed to establish a central station at Bernstadt. The electric lighting question is also under consideration at Ludwigsburg. The municipal authorities of Coblenz, in addition to the tramway scheme mentioned above, have also appointed a committee to inquire into the electric lighting question. Telephonic communication is now available between this city and Velten. A central electric lighting station is rapidly approaching completion at Predazzo in the Tyrol; water power is being used. Tenders are about to be invited for the establishment of a central station at Brunn. The local authorities of Rumberg have just decided upon the establishment of a municipal central station in the town. It is stated that Messrs. Schuckert and Co., of Nuremberg, in conjunction with two other firms, have undertaken the construction of the Gosan electric railway near Linz. The line will be about 60 kilometres long.

Tyneside Geographical Society.—On December 30 a lecture was delivered by Mr. Philip Dawson, A.M.I.C.E., A.I.E.E., member of Tramways Institute of Great Britain and Ireland, on the subject of "Electric Traction" in the Lovaine Hall of the Tyneside Geographical Society, Newcastle. Captain Noble presided, and there was an unusually large audience. In the course of his lecture Mr. Dawson said: "It is a matter of common knowledge that animal power has long since proved wholly inadequate for the requirements of modern metropolitan life. There is no engineering question of more pressing present interest to the British public at large than the extension of rapid transit facilities. Until a very recent date it was necessary for us to look wholly to America for those later developments in rapid transit extension which have led to the introduction of improved mechanical traction on a large scale. The results obtained have been so rapid and surprising, and, as a whole, so satisfactory, that they merit our most careful attention. In 1890 there were 2,523 miles of electrically operated track and 5,592 motor cars within the United States of America and Canada. In July, 1895, 10,752 miles of trolley wire had been erected, furnishing current for 35,004 electric cars. Approximately, these figures mean an investment in equipment of £50,000,000 sterling. In 1890 about 60 miles of electric lines were in operation. To-day there are approximately 500 miles of elevated conductors and 1,500 motor-equipped cars, while the lines under contract easily equal, if they do not considerably exceed, the sum total of all that has heretofore been completed. By far the greater proportion of European electric tramway installations are to be found in Germany, but during the past year great activity has been shown in France as well. Comparatively little has yet been done in the British Isles, but there is every present appearance of extensive installations being shortly undertaken. Dublin, Bristol, and Coventry are now running. The electric tramways of the Isle of Man, South Staffordshire, Leeds, and Guernsey are undoubted successes. On the question of tramways in general, the attitude taken in Great Britains is distinctly opposed to that of all other countries. British regulations are by far the most severe, and is difficult to see why their stringency should not be relaxed to some extent. With the gradual change from animal to mechanical means of traction, most, if not all, of the objectional features of the tramway have been eliminated. If American and Continental experience has proved anything, electricity surpasses all other methods of motive power in its general fitness for tramway and light railway service. It admits of a constant service of comparatively light cars or trains at reasonable cost, of wide variations of speed, of elasticity sufficient to meet the demands of great temporary increase in passenger traffic, of re-equipment without extensive interference with the highway, existing cars, or any public service. It is essentially clean, safe, and controllable. All that has been said is especially applicable to the trolley wire system, which is the only one that has received any wide acceptance. The conduit has still to demonstrate its efficiency on a large scale. The trolley wire avoids the great expense and manifold disadvantages attendant upon reconstruction of roadway, and interference with existing sub-surface sewers, gas and water pipes and mains, telegraph, telephone, and lighting cables, etc." After referring to the Bristol tramways, Mr. Dawson said that on the Continent Genoa with its marble palaces, Milan with its magnificent piazzas and Duomo, Rome, Florence, Dresden, Leipzig, Nuremburg, Hamburg, Bremen, Brussels, Havre, Marseilles, Rouen, Lyons, etc., do not find that well-established trolley lines spoil their beauties. In conclusion, he remarked: "A few words must be said as to the comparative merits of electricity as against cable traction. For the broad and straight thoroughfares of great cities, where enormous traffic is to be handled and heavy grades to be worked, the cable is still unequalled. If, however, the traffic is not so great as to assure a service of cars or trains one minute or less apart, the cable is hopelessly behind electrical motive power. The tremendous expense of a cable installation can only be met where these favourable conditions are to be found. Curves are well nigh fatal to the economical operation of a cable line, and it is utterly unsuited to a service which requires that outlying districts be brought into touch with metropolitan centres. This is so much the case that America furnishes numerous illustrations of cable lines abandoned for electric trolley lines. I may cite St. Louis, Denver, San Francisco, St. Paul, and Minneapolis as conspicuous examples of the substitution of electric power for cable. The cable has no elasticity. The electric car can be run effectively where no other known means of traction will meet expenses. It may safely be taken that few, if any, cable tramways will be equipped in the future, and those only in the great arteries of traffic of the greatest cities of the world. I can see no reasonable alternative to the electric motor. It possesses the maximum of advantages and the minimum of drawbacks. It has a future unquestionably in this country and the Continent as great as its present in America, and I feel assured that no opposition can be so strong as to bar its progress." A discussion followed.

AYR ELECTRICITY WORKS.

Town after town is municipalising its artificial lighting, and in this manner adopting the electric light. The latest burgh to enter the ranks of the electrically lighted is Ayr, the capital of the county of Ayr. This town is one of the best known in Scotland, standing on a magnificent site on

BAILIE WILLIAM URE,
PRESENT CHAIRMAN OF ELECTRIC LIGHTING COMMITTEE.

the sea-coast at the head of the bay of Ayr. Its charter of incorporation was first granted in 1202 by William the Lion, who conferred upon the burgesses the whole of the lands of the parish with many valuable privileges. This charter was confirmed by Alexander II., who added the adjoining parish of Alloway, and these charters were

MR. H. D. WILLOCK, PROVOST OF AYR.

ratified by Robert Bruce. The lovers of Ayr say its bay is unrivalled for scenery. To the north are the islands of Cumbrae, the Bute hills, and in the distance the Argyllshire mountains, with mighty Ben Lomond towering over all; to the west, across the sea, is seen the Irish coast, and near the Ayrshire coast is the Craig of Ailsa, not to mention the Isle of Arran, and away behind that the Mull of Cantyre. Ayr can boast a long roll of historic names, three of which will last while history endures—Burns the poet, Scotus the scholar, and McAdam the engineer.

A retrospect of the history of the electric lighting movement in Ayr shows that as far back as 1878 a Mr. Horton, agent for Gramme's patent electric machine, gave two exhibitions of the light in Ayr, and at that time admiration was expressed on all hands at its brilliancy and power. Several members of the Town Council then expressed a strong desire that at least an experiment on a small scale might be made at some part of the town specially adapted for the use of the light, as it was thought that the exhibitions had not fully solved the problem of the applicability of the system to purposes of street lighting. This was Ayr's first experience of electric light, and apparently nothing resulted from it. In 1889, when the great boom occurred among electric lighting companies, during which a number of them made raids upon several of the cities and burghs of Scotland, the ancient burgh of Ayr came in, amongst others, for a share of the attentions of these companies. Two companies—the Scottish House-to-House Electric Company, Limited, and Messrs. Norman

MR. JAMES SMITH,
FIRST CHAIRMAN OF ELECTRIC LIGHTING COMMITTEE

and Sons, Limited—at that time wrote to the town clerk of Ayr intimating that they intended to apply to the Board of Trade for a provisional order for the electric lighting of the burgh. Both letters were laid before the Works Committee of the Ayr Town Council on July 4, 1889, and were remitted by that committee to the Lighting Committee. A special meeting of the Town Council was convened for August 12, to take into consideration the action of the two companies, and also to consider the whole question of electric lighting, with a view to the introduction of electricity as a means of lighting the burgh. The matter was freely and fully discussed at this meeting, and a motion to the effect that the Commissioners should take the lighting of the burgh into their own hands, and thereby preclude any company from coming in without the consent of the Commissioners, was unanimously carried. It was also at the same meeting remitted to the Lighting Committee with powers to obtain, and thereafter carry out, a provisional order for the lighting of the burgh by electricity. The committee, however, was in no hurry to press on the work, hoping to gain experience by delay, the more so, as at this time most of the installations then in progress were being promoted by companies—few burghs in England and none in Scotland having undertaken their own electric lighting.

Digitized by Google

At a subsequent meeting of the Town Council held on November 14, 1889, it was unanimously agreed to at once take out a provisional order in the name of the Commissioners, and thus thoroughly check any encroachment by any company, and a provisional order was accordingly obtained by the Commissioners. Having armed themselves with this order, the committee proceeded to leisurely discuss the question of ways and means and to collect information as to the best and most profitable system to adopt. The impression was then pretty general that sufficient motive power for an installation could be obtained from either of the Rivers Ayr or Doon, and as the committee considered that water power was not only the best, but also cheapest, they availed themselves of the services of Mr. Frank Christie, of Chelmsford, a hydraulic engineer of considerable experience, in making a survey of both rivers to ascertain their capacity for the purpose. In the beginning of 1894 Mr. Christie submitted a very exhaustive report, which demonstrated clearly that all that could be got out of either of the two rivers was only about 500 h.p., at a cost of about £18,000. Had more than 500 h.p. been required at a future time it would have been necessary, therefore, to supplement the water power with steam power. This idea was eventually abandoned.

During the interval between Mr. Christie's survey and report the committee, who were acting on the defensive rather than the aggressive, had been compelled to make application on two occasions for an extension of their provisional order, both of which applications—the first in June, 1892, and the second in 1893—were granted, and early in 1894 the committee resolved to bring the matter to a final issue. With this end in view they commissioned Mr. John Eaglesham, the burgh surveyor, to visit Leeds, Blackpool, and one or two other places where there had been electric light stations built; and when that gentleman returned from his tour of inspection he reported so favourably of the system adopted in Leeds and Blackpool, and also of Mr. Robert Hammond, the engineer who had carried through the work connected with these installations, that the Commissioners commissioned Mr. Hammond to survey the burgh and draw up a report. This Mr. Hammond did, and his report was submitted to the Commissioners at their meeting in May. At this meeting an offer was submitted by the Caledonian Electric Supply Company, Edinburgh, to make terms with the Corporation whereby they would take a transfer or a lease of the provisional order. A lengthy discussion ensued, during which several of the Commissioners expressed themselves in favour of making terms with the company, but it was finally decided by a majority of 10 votes to 7 to keep the matter in the hands of the Commissioners, and it was left to the Lighting Committee to carry out the arrangements for giving effect to the resolution.

Site of the Works.

The first matter to which the committee turned their attention was the fixing upon a site for the erection of the works, and at the meeting of the Council held in June, 1894, full power was granted to them to fix upon and purchase a suitable site. In July the intimation was authoritatively made that the committee had fixed upon a vacant space of ground, belonging to the Corporation, situated in South Harbour-street, near the barracks, and it was said that by utilising this ground for the purpose upwards of £1,000 would be saved to the town. Mr. Hammond, the engineer, strongly approved of this site. A difficulty, however, arose when the Commissioners negotiated for the purchase of a piece of ground adjoining, which was considered necessary for further extensions which might require to be made in future, and the site was abandoned. Several other sites were under consideration, and the committee finally selected a site in Mill-street, situated on the south bank of the River Ayr, at a cost of £1,550. The borings on the site showed that satisfactory foundations would be obtained.

Cost of Plant, Buildings, etc.

Tenders having been invited for the supplying of plant, etc., no less than 49 were received. Some of the tenders were for the whole of the projected plant and works, while others were for parts only. The lowest offer by one firm for the complete work was £12,760, while the lowest offers from the various firms for the different parts of the work amounted to £11,834. Considering that almost £900 could be saved by dividing the work into sections, the committee felt justified in following this course, and the tenders were accepted as follow:

Plant.

Part I. of Section A—boiler-house plant: Messrs. Penman and Co., Glasgow, £950

Part II. of Section A—piping, etc, in connection with boiler-house plant: the Corporation undertook under the supervision of Mr. Hammond and Mr. Pink at a probable cost of £800.

Section B—engine house plant: Messrs. Siemens Bros. and Co., Limited, London, £5,940.

Sections C and F—switchboards and instruments and arc lamps, posts, etc.: Messrs. John Fowler and Co., Limited, Leeds, £988. 5s.

Section D—cables and culverts: Callender Bitumen Telegraph and Waterproof Company, Limited, London, £1,842. 18s. 9d.

Section E—transformers and boxes: Messrs Swinburne and Co., Limited, Teddington, £420.

Section G—meters: Messrs. S. Z. de Ferranti, Limited, London, £590. 13s.

Section H—travelling crane, etc: Messrs. Carrick and Ritchie, Edinburgh, £192. 10s.

Buildings.

Excavator, brick, and mason's work: Mr. Robt. Hutchison, £3,303. 6s. 4d.

Carpenter, joiner, and painter's work: Messrs. D. and J. Milligan, Ayr, £1,146. 13s. 4d.

Plumber and slater's work: Messrs. W. Highet and Son, Ayr, £356. 10s.

These are the original prices in the tenders without the extras which have inevitably crept in. One extra in particular is worthy of mention; it is the sum of £990. 12s. 4d., which was involved in an extension of the electric main along Miller-road and Alloway-place, a district not included in the original area to be lighted. The figures given above for purchase of site, plant, and buildings, and including the extra sum for the extension of the main referred to, total up £19,071. 8s. 9d., and this, of course, does not include the engineer's fee nor the salaries of the superintendents appointed to look after the erection of the plant and buildings. Another item to add is the interest on the sum of £15,000 which the Corporation were authorised to borrow for a period of 30 years. Taking all these items into consideration, along with the extras, the total cost may be estimated at over £20,000. Subsequently the Commissioners were authorised to borrow an additional £5,000, thus bringing the amount borrowed up to £20,000.

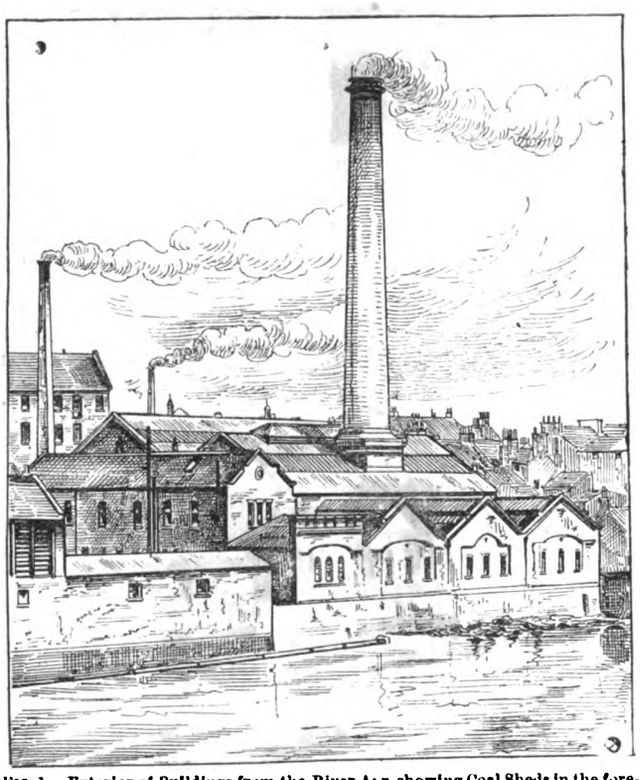

Fig. 1.—Exterior of Buildings from the River Ayr, showing Coal Sheds in the foreground, Boiler-house and Engine-house behind, and the Office Wing to the left.

Description of Buildings.

The designs for the building were prepared by Mr. H. V.

Digitized by Google

Eaglesham, architect, and this gentleman has also superintended the carrying out of the work. The buildings are entirely of brick, lined inside with Brodie's pressed brick from Sanquhar. On the ground floor are situated the engine-room, measuring 69ft. by 34ft. and 41ft. high to the apex of the roof; the boiler-room, 69ft. by 45ft. 6in. and 33ft. high; the condenser pit, 24ft. by 16ft.; the test-room, 12ft. by 18ft.; coal-sheds, 69ft. by 25ft.; workshop, 27ft. by 16ft.; mess-room, 10ft. by 16ft.; store, 9ft. by 16ft.; lavatory, water-closets, etc. Upstairs are the offices, switch-room, lavatory, etc.

The interior of the engine-room presents a fine appearance. Running right round is an enamelled brick dado, 5ft. high, surmounted by a band of blue bricks. At a height of 22ft. there is a travelling crane, running on an iron rail, carried on piers 3ft. square and arched between. These piers and archings are also of enamelled brick, and are founded on the solid rock at a depth of about 15ft. below the level of the floor. The foundations of the engines are also on the solid rock, and are brought up to the level with concrete. At the level of the crane rail there is a wooden cornice which extends round the whole room. The roof is formed of iron couples, with pitch-pine purlins and chamfered boarding. The roof-light extends the full length on both sides of the apex of the roof. Ventilation is obtained by means of two of Boyle's patent ventilators. The floor is formed with concrete tinted with oxide of iron. The wall at one end of the engine-room is only temporary, and is built so as to allow of future extension.

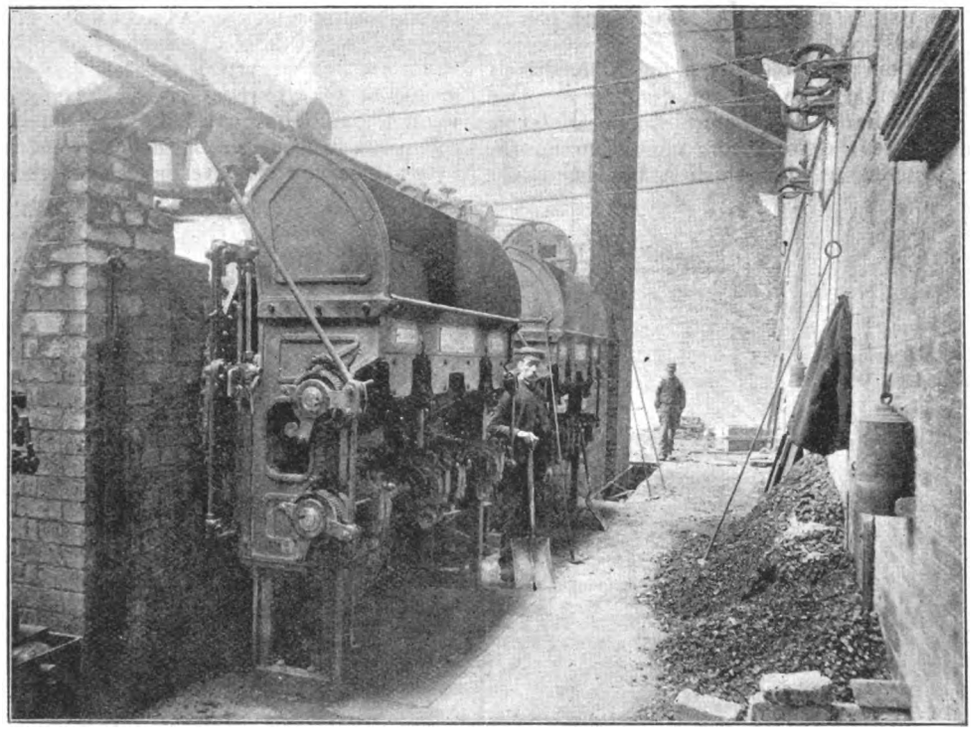

FIG. 2.—Front View of Boilers, showing Vicar's Mechanical Stokers.

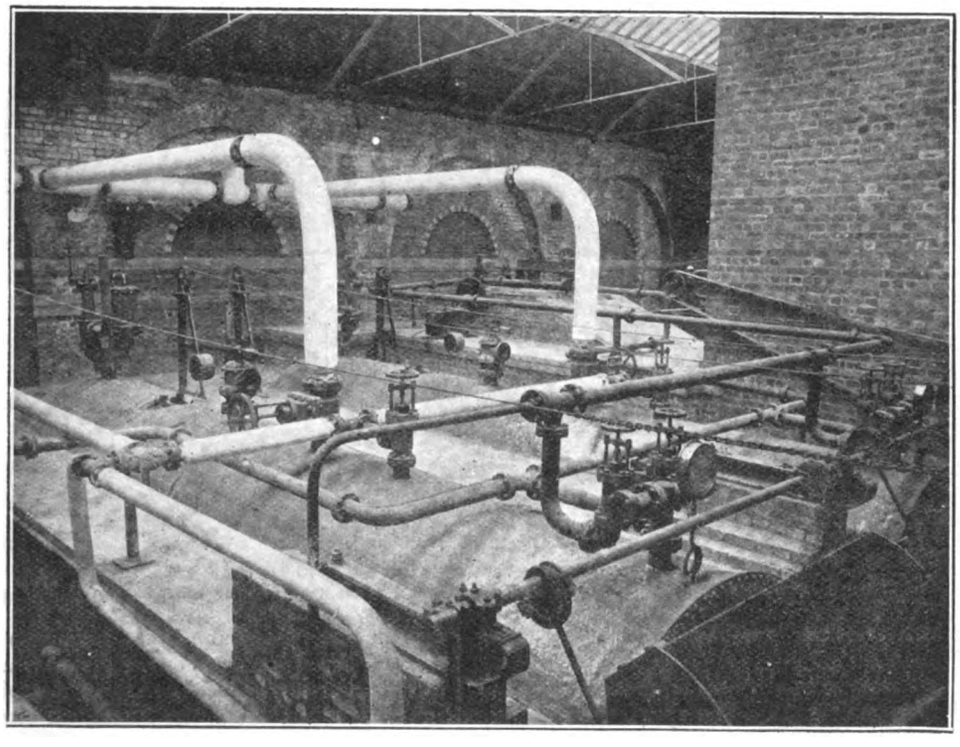

FIG. 3.—Top View of Boilers, showing Boiler Connections.

Digitized by Google

Adjoining the engine-room is the test-room, which is lined with narrow lining and stained and varnished.

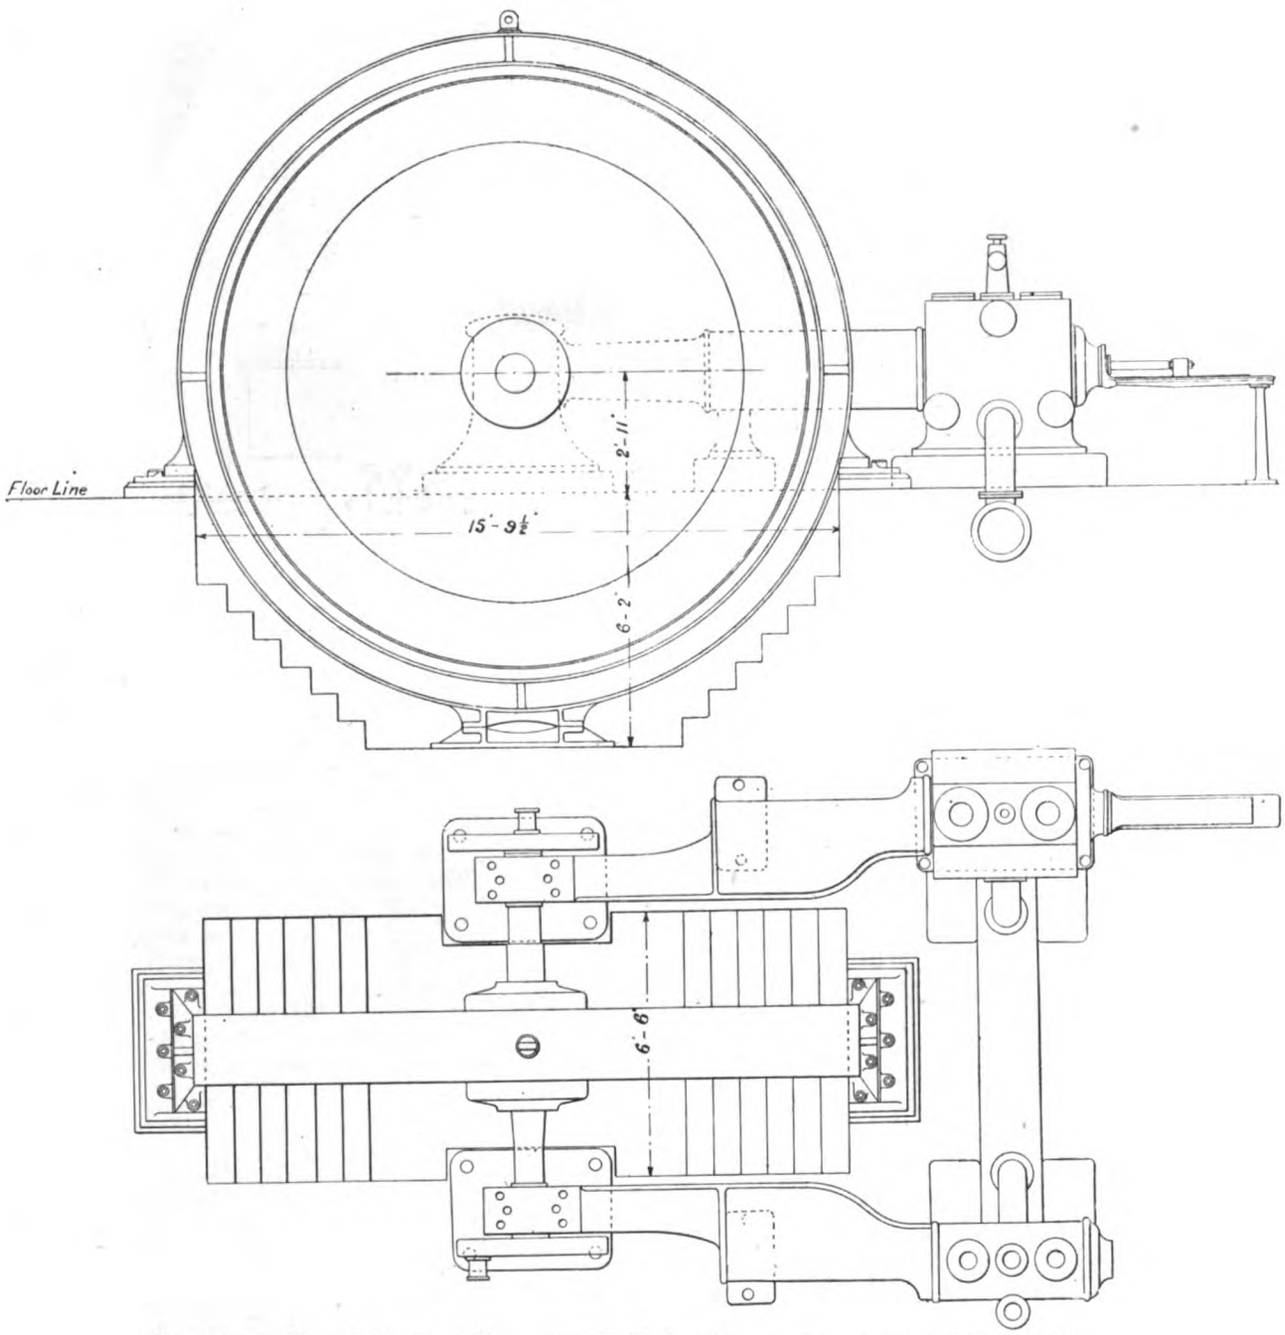
The boiler-room adjoins the engine-room, and has a roof of similar construction, the only difference being in the means of ventilation, the boiler-room being ventilated by a louvred ventilator. The chimney stalk, which is 12ft. square at the base, rises to a height of 120ft., and has its foundation on the solid rock.

The coal-sheds adjoin the boiler-room, and immediately behind the boilers openings are left for drawing the coal from the coal-sheds to feed the mechanical stoker. Entering off the boiler-room are the workshop, mess-room for the employés, store, condenser pit—which is 6ft. below the level of the boiler-room floor—and the lavatory and water-closets.

The private entrance to the offices is at the south-east corner of the buildings (Fig. 1). The stair leading to the switchroom and offices is of pitch pine, with wooden balusters and handrail. At the top of the stair to the right is the switchroom, and to the left a long corridor, with electrician's, engineer's, and general offices, and lavatory entering off it. The switchroom is open on the side towards the engine-room, having on that side only a wooden balustrade. From it an excellent view of the engine-room can be obtained. The offices are supplied with telephone connection, and are fitted in first-class style.

Steam Generating Plant.

The boiler-house plant, as already stated, was supplied by Messrs. Penman and Co., of Glasgow. The boilers are two in number, of the Lancashire type, each 28ft. long by 7ft., with two flues each 2ft. 9in. diameter, with four water-circulating cross tubes in each. The boilers are constructed throughout of mild selected steel boiler plates; each circumferential ring of the shell is made of one plate, the longitudinal seams are butt-straped in and out and riveted together by means of four rows of rivets, the circular seams are lap-jointed and double riveted. The flues are on the anti-collapsive flanged-seam principle, constructed throughout by machinery. The rivet holes throughout the boiler were drilled after the plates were bent into position, and the riveting throughout performed by hydraulic power. They were constructed under the supervision of the Engine Boiler and Employers' Liability Insurance Company, and were designed for a daily working pressure of 140lb. per square inch.



FIGS. 4 AND 5.—Plan and Elevation of Siemens 100-K.W. Flywheel Alternator driven by Marshall Horizontal Engine.

Each boiler is capable of supplying steam to a 250-h.p engine at full load. Each boiler is fitted with a Vicars mechanical stoker, by which an almost smokeless fire is obtained. These stokers, which can be seen in Fig. 2, are driven by a five-kilowatt, or about 8 h.p., electro-motor, supplied by Messrs. Mavor and Coulson, Glasgow, and great care has been taken to avoid any sudden

Digitized by Google

rush of current on switching on the motor, which would cause a temporary blink in the lights.

In these Vicars stokers the fuel is fed from a hopper into two boxes, from which it is gradually pushed by alternately reciprocating plungers into the furnace; it then falls on the firebars, which by a slow reciprocating movement carry the burning mass gradually backward. The supply of fuel and the travel of the firebars can be regulated with facility, independently of each other, by means of a simple mechanical combination. The travel of the bars may also be adjusted in length up to 4in. The alternate firebars are lowered and drawn towards the front of the furnace, and then all the firebars travel inwards together. The motion is derived from a driving shaft, on each end of which an eccentric is fixed, working a ratchet wheel and pawl, by which a transverse shaft at the front is caused to

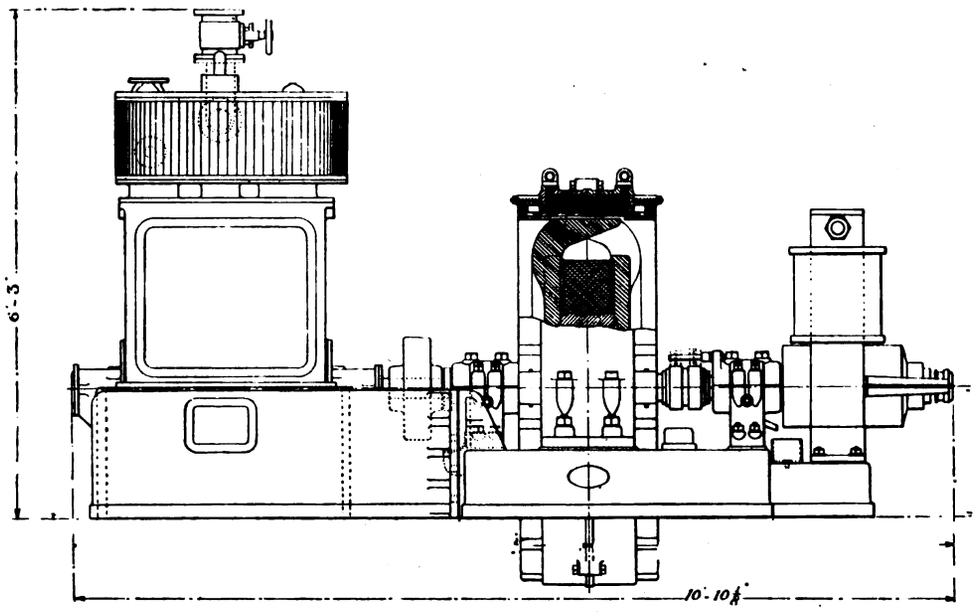


FIG. 6.—Sectional Elevation of 25 K.W. Siemens-Bellis Steam Alternator.

revolve. By means of cams on this shaft the horizontal movements of the firebars are effected. The speed of this motion can be regulated to from 30 to 120 turns of the shaft per hour. The furnace can, when required, be fed by hand through a doorway between the two pushing rams.

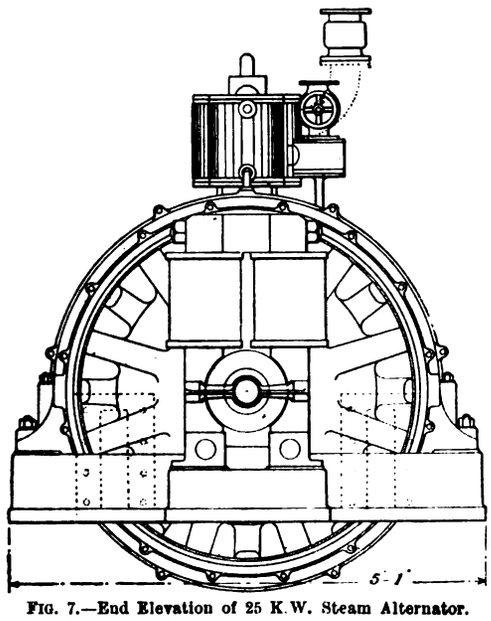

FIG. 7.—End Elevation of 25 K.W. Steam Alternator.

The water for the boilers is drawn from a hot-well underground, capable of holding 3,000 gallons, into which the overflow from the condenser and the hot-drains run. The water is forced into the boilers either by an injector capable of supply 1,200 gallons per hour or by a Worthington pump of the same capacity. The feed-water is heated before entering the boilers by a fuel economiser, consisting of 48 tubes, constructed by E. Green and Son, Limited, of Manchester and Wakefield, which is placed in the flue between the boilers and chimney, suitable provision being made for examination or cleaning purposes without stoppage of the boilers. The apparatus is constructed from strengthened patterns throughout and fitted with a number of recently patented improvements.

The condensing plant was supplied by Messrs. Alley and Maclellan, of Glasgow. The air-pump and jet condenser is of the horizontal direct double-acting type, of ample capacity for maintaining a vacuum of 26in. when the engines are developing full power. Steam is taken direct from the boilers to the cylinder, which exhausts direct into the condenser. The injection water is taken direct from the river, and is discharged into a hot-well. A separate connection is made to the water-main for the purpose of getting a vacuum when starting the pump. By an arrangement of valves the engines may exhaust either into atmosphere or into condenser as required. Provision is made so that a duplicate pump and condenser may be put down at a later date. The condenser pit is 6ft. below the engine-floor surface. The condensing water is drawn from the dam about 300 yards up the river through a 12in. pipe, and has an overflow of the same dimensions. From the main existing pipe and the intake and overflow pipes two services are made for future connections.

The steam and exhaust pipe work was done by men employed by the burgh, under the supervision of the burgh engineer. Fig. 3 shows these pipes over the two boilers, and the connections to the feed-pumps, etc.

GENERATING PLANT.

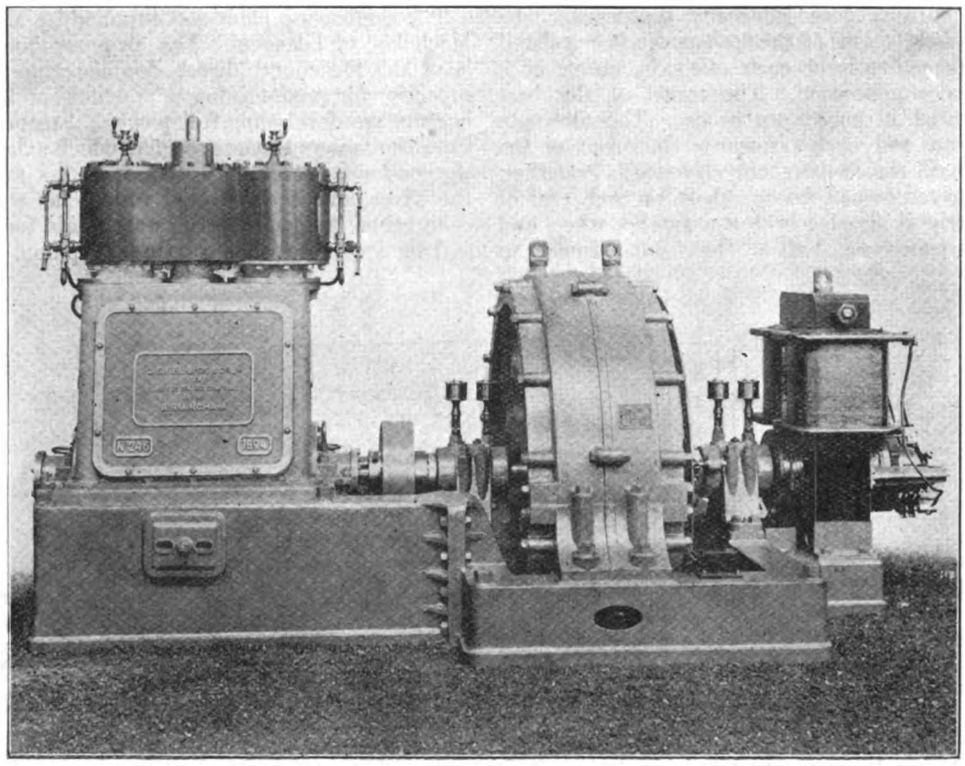
Messrs. Siemens Bros. and Co. obtained the contract for this part of the work, and supplied two large alternator sets capable of giving 100 kilowatts each, one smaller 25-kilowatt set, with its own exciter on the same shaft, and two exciter sets of 10 kilowatts.

The two engines for driving the large flywheel alternators (Figs. 4 and 5) were manufactured by Marshall, Sons, and Co., Limited, of Gainsborough. They are of the horizontal coupled compound type, each with high-pressure cylinder 14½in. diameter, low-pressure cylinder 25in. diameter, both having 32in. stroke. The cylinders are steam jacketed, the inner barrel being cast separately of a special hard mixture of iron, and tightly forced into the main casting of the cylinder. The clearances are carefully worked out, and the inside faces of the covers and both sides of the pistons are turned and polished. The governors are Dr. Proëll's patent, with two valve-releasing gear and Corliss exhaust-valves, and the governors are chain-driven direct from the crankshaft. The crankshaft bearings are of extra strength, and are arranged with adjustment, not only at the sides, but underneath, so that the crankshaft can always be adjusted, as these engines have the armatures of the dynamos fitted on the shaft in the place of a flywheel. All the wearing parts

Digitized by Google

are amply large. Brass bushes and neck rings are provided for all rods, with patent metallic packing for the stuffing-boxes. Pillars and handrails are placed round the discs, connecting rods, and dynamos, and the engines throughout are fitted up in the first-class style for which the firm are renowned. These engines, running at 95 revolutions per minute, are each capable of giving 175 i.h.p. when supplied with steam of 125lb. pressure. The whole of the engines have their bearings fitted with special oil-pumps, and the oil is forced through all bearings at pressure of 2lb. to the inch. All the oil is collected at the base of the engines and runs by a common drain to a small sump in the corner of the engine-house, from which it is pumped into filters, and after being filtered is ready for using again. All waste is thus avoided.

The alternators, which are of the Siemens O $^{170}/_{12}$ type, are built up as flywheels to these engines. The general outlines of these alternators and engines can be seen from Figs. 4 and 5, but unfortunately the details of the alternators are not shown. The field magnets, which are fixed to the rim of the engine flywheel, revolve, while the armature, which is fixed, is arranged outside the magnets.



Belliss 50-h.p. Engine coupled to Siemens 95-K.W. Alternator and Exciter.

The field-magnet system is built up on the cast-iron flywheel in the following manner On each ide of the rim are clamped four sections of a cast-steel check, having a number of pole-pieces projecting inwards across the external surface of the wheel, as shown in Fig. 6. The poles, bolted on the opposite side, nterleave with these, so as to form a series of 76 alternate poles. The exciting coil is wound on the cast-iron rim, and held in position by the steel cheeks. A cast-iron rim, 17ft. 3in. in diameter, surrounds the magnet system and supports the armature laminations. The

FIG. 9.—View of the Conduit for High-Tension Mains, showing Draw Box

Digitized by Google

wrought-iron sheet presents a smooth surface to the magnets, and to the face of it are bolted, by means of special brackets, 76 coils of flat copper strip, wound edge-ways. The flywheel is not keyed to the main shaft, but is driven by means of two spring couplings placed one on each side of the flywheel. The wheel has projecting arms on each side, which come in the recesses of a star-shaped casting keyed to the shaft. Between the adjacent arms thus formed, steel springs are placed, which give a flexible drive, and hence reduces the synchronising current. The output of each of these alternators is 50 amperes at 2,000 volts, the frequency being 60 ~ per second.

The other three engines were supplied by Messrs. G. E. Belliss and Co. The engine for driving the day-load alternators is capable of giving an ordinary load 50 i.h.p., and will keep up 60 i.h.p. for a short time on emergencies, with a steam pressure of 125lb. exhausting into the condenser at a speed of 360 revolutions. When the condenser is not in use, the boiler pressure will be increased to 140lb. enables the engine to be run with a minimum of attention. Another special feature of these engines is the arrangement of the slide valves, requiring one eccentric and rod only.

The alternator coupled to this engine is of Siemens's O $^{50}/_{12}$ type, of same general design as the large alternators described above. It can give an output of 12·5 amperes at 2,000 volts. The section (Fig. 6) shows the construction of this machine. The exciter coupled to the extensions of the shaft is a direct-current machine of the H. B. $^{12}/_{8}$ type. The output of this exciter is 30 amperes at 100 volts.

The two smaller sets for exciting the large alternators consist of two Belliss engines, generally the same in their leading features as the day-load engines above described, but of smaller dimensions. They were designed to indicate 20 h.p. ordinarily and 30 h.p. on emergency, at a speed of 500 revolutions, exhausting into condenser. They drive Siemens H. B. $^{9}/_{18}$ dynamos giving out 100 amperes at 100 volts. Either of these is capable of exciting all the alternators at one time.

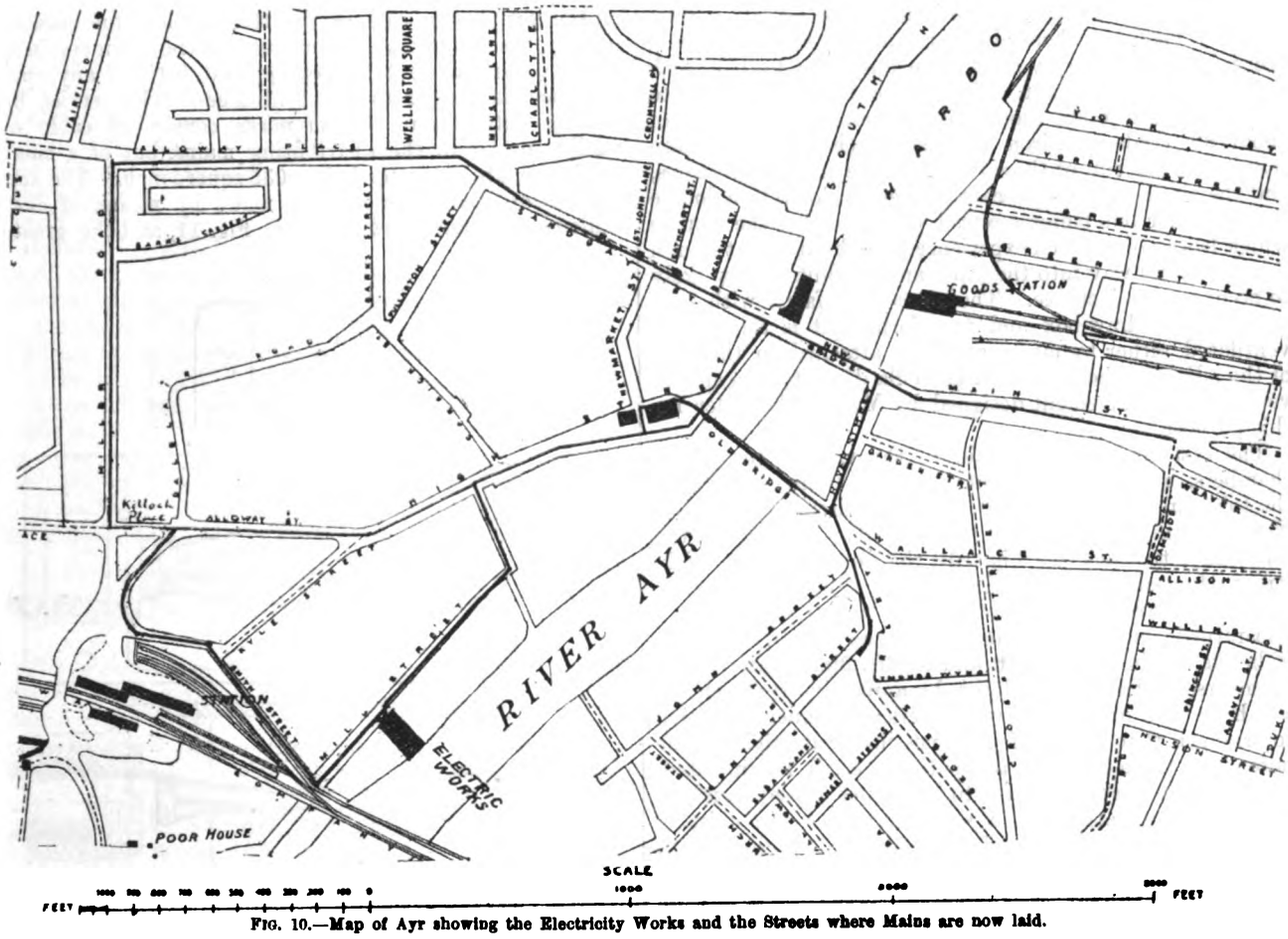


FIG. 10.—Map of Ayr showing the Electricity Works and the Streets where Mains are now laid.

This output was satisfactorily maintained on the tests of the combined sets at the makers' works. At the same time the performance of the engine on the governor was tested with the following results. On the full load being switched off suddenly the momentary increase of speed was found to be only 4 per cent., the permanent variation being the same. For an engine fitted with throttle-valve governor this result, so far as the momentary increase is concerned, is very good. It is largely due to the large flywheel effect of the heavy alternator in conjunction with the excellence of the governing arrangements. Two views of this engine and alternator are shown (Figs. 6 and 7), and Fig. 8 is a perspective view of the same.

There are two sets of cylinders, the cranks being set opposite each other, and steam being admitted simultaneously to the top of one cylinder and the bottom of the other. The reciprocating parts are balanced, and thus a high speed is made possible without setting up undue vibration. The high-pressure cylinders are 7½in. diameter, and the low-pressure cylinders 12in. diameter with 6in. stroke. These engines are fitted with a system of forced lubrication, which not only conduces to their noiseless working, but being essentially automatic in its action

SWITCHBOARD.

This was made, under the Lowrie-Hall patents, by Messrs. J. Fowler and Co., of Leeds. It is arranged for three alternators and two circuits, with provision for extension up to six alternators and four circuits. The board is designed to maintain high insulation, the bases being entirely of slate, and the metallic portions of the switch plugs are carefully insulated and fixed on ebonite bases. The form of the plugs and that of their corresponding terminals is that of a rectangle, nearly square in dimensions, in order to prevent the plug being inserted wrongly. The switchroom is so arranged as to be easily accessible at the back for examination of connections, etc., the oak frame on which the switch panels are fixed forming a false wall to the switchroom. The switchboard is fitted with signalling arrangement, with gong attached, having a suitable dial in the engine-room. The board also includes a complete synchronising arrangement and hospital shunt for occasionally running one circuit separately in connection with any alternator by means of jack cords and flexible cables. A suitable artificial load is provided for testing the plant prior to the running on the lights, and consisting of a resistance frame arranged with switches, so that loads of 25, 50, 75, or 100 kilowatts can

Digitized by Google

be obtained at will. The whole of the board, in addition, being highly insulated is thoroughly protected from accidental contact on the part of the attendant. The actual size of the switchboard is 12ft. wide by 11ft. 6in. high.

Distribution.

The whole of the mains and cable were manufactured and laid by the Callender's Bitumen Telegraph and Waterproof Company, Limited. From the central station in Mill-street, where the current is generated at 2,000 volts, it is carried by means of concentric cables to certain points in the town, at which transforming apparatus is placed in underground chambers. It is then converted into a low-pressure current, and thence distributed along the network of low-tension mains to the various consumers, to whom it is supplied at a pressure of 100 volts. Two separate circuits leave the works, each one contained in a separate conduit. This conduit consists of a cast-iron pipe having 4in. internal diameter. It is made to the Post Office specification as to weight and thickness, and is dressed both inside and out with Dr. Angus Smith's preservative compound. The pipes themselves are in lengths of 9ft., and are joined together by spun yarn and blue lead at each socket and faucet joint. Great care has been taken to make all these joints thoroughly sound. At intervals of about 80 yards cast-iron draw-boxes (Fig. 9) have been inserted in the run of these pipes. These are solid castings, and the manhole giving access to them is closed by a double lid, the inner one being screwed down, so that the trouble which has so often been experienced in other towns through gas finding its way into the pipes and conduits is not likely to occur in this instance. The outer lid is faced with concrete. Each draw-box and transformer-pit is thoroughly ventilated, either by means of a pipe attached to the wall of the adjoining houses or (in the villa district) by a special ventilating arrangement designed by Messrs. Callender for this purpose.

The cast-iron pipes are laid to the various converting chambers, and, as at present arranged, there are, within the town area, three of these on No. 1 circuit and four on No. 2, making seven in all. These seven are placed in the following situations (see Fig. 10): the Town Head, Garrick-street, Hope-street, Town Hall North, Town Hall South, Newmarket-street, Cross-street. The actual transforming apparatus is enclosed in a small box or chamber constructed of bricks, set in cement, 4ft. 4in. by 4ft. 8in. in size. These chambers, or boxes, are closed by a massive cast-iron lid, and have both inner and outer covers; the inner one being so arranged that it is, as far as possible, watertight. The outer is in three sections, so as to be easily manipulated. Every endeavour was made to construct these chambers under the footpath, but in some instances the existing cellars and other obstructions rendered it necessary to place them in the roadway. The length of each of the high-pressure circuits is about 1,160 yards. The feeding mains are of Callender's high-pressure concentric cables, having a sectional area on each conductor of ·062 square inch. Each of the conductors is insulated by a solid dielectric of bitumenised fibre, and the outer dielectric is sheathed with a solid tube of lead, which is made direct on the cable under great hydraulic pressure. The cable is then yarn braided and thoroughly compounded, so that the lead has a mechanical protection between it and the iron pipes. The pipe line was first laid complete, and the lengths were then carefully measured between the various boxes and transformer chambers. The high-tension cables were then made in exact lengths to suit the work, so that the joints which were necessary to unite the factory lengths into continuous mains when laid should in all cases occur at draw-boxes, so as to be easily available at any time for inspection or otherwise.

The quantity of cable provided for under the original contract was 3,080 yards, and this has been laid. In addition to this it has already been found necessary to extend the mains to the residential district, and 2,060 yards of similar high-pressure cable have been laid, making 5,140 yards in all, or nearly three miles. No difference in the system has been made in the residential district, except that the cast-iron pipes used have been 3in. in diameter. The low-pressure mains radiate from the transforming-chambers throughout most of the important streets in the burgh, and consumers are connected to these mains. The cables used for these low-pressure mains are also Callender concentric and lead-sheathed, and, so far, differ in no respect from the high-pressure mains, except that their section is ·097 square inch, and their insulation is of a much less degree. Over the lead sheath they are yarned and strongly armoured by two ribbons of steel. They are then dressed with a special preservative material, and then yarned and passed through a bath of asphalte compound as a preservative. These cables are laid in the trenches along with the high-pressure pipes, and require no protection other than their own armour.

Low-pressure mains have been laid in the streets shown with black lines in them in Fig. 10, and it has already been found necessary to extend them beyond the original compulsory area into the residential district. The total quantity of low-pressure cable provided under the contract was 3,080 yards, and 2,418 yards in addition have already been laid, making over three miles in all. Arrangements are made on the low-tension side of the transformers for cross-connecting the mains so as to cut out the transformers in the event of an accident happening, and little, if any, inconvenience is caused to the consumers. The service lines leading into consumers' premises consist of cable of a similar make to the distributing mains, but of a smaller section, each conductor being ·035 square inch. The actual connection with the main is made by means of one of Callender's patent service boxes, Fig. 11, and the greatest

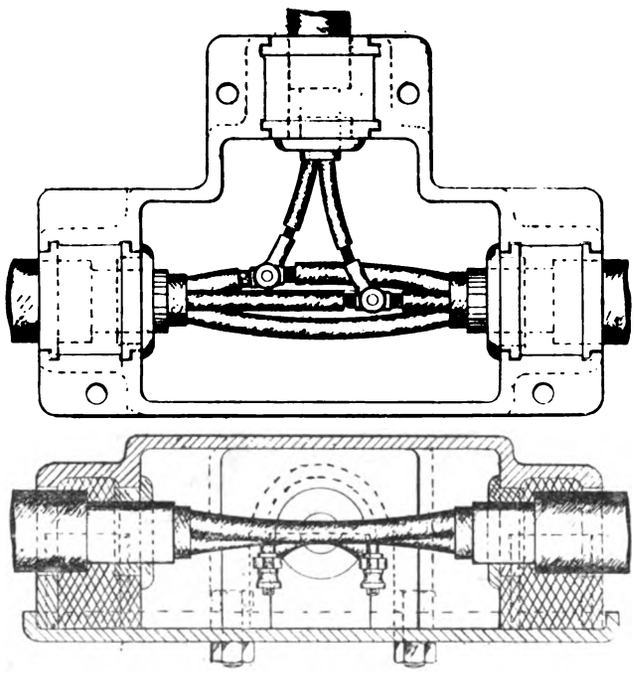

Fig. 11.—Callender's House Service Box.

possible care has been taken in making these connections. The service line ends inside the consumers' premises in one of Reid's patent fuse-boxes, which serves at the same time as a terminal box for the cable, and complies with all the requirements of the Board of Trade for the protection of consumers. There are at present 71 houses connected with the distributing mains, and applications are being received almost daily from would-be consumers. In addition to the private lighting thus provided for, there are 25 arc lamps in various parts of the town. They are connected by similar armoured Callender cable with the low-pressure mains.

The insulation of the cables has been most carefully attended to; that of the high-pressure feeders is over 5,000 megs per mile, and of the low pressure distributors 1,000 megs per mile. In addition to this, all the cables have been carefully tested with a pressure three times that which is to be used in actual working.

The transformers and transformer-boxes were supplied by Messrs. Swinburne and Co., of Teddington, and the arc lamps, posts, etc., by Messrs. J. Fowler and Co. The arc lamps are so constructed that the striking of the arc and the

Digitized by Google

feed of the carbons are separately effected, although governed by one electromagnetic device, and through one mechanism. The feed is regulated by a detent and fan. The controlling device is a solenoid connected in series with the arc and a floating laminated iron core. The feeding mechanism consists of three wheels, forming a differential gearing, the striking acting on one wheel, while the feed acts on the other. An intermediate wheel connects the carbons to the striking wheel and also to the feeding wheel. Through this intermediate wheel the striking gear or the feeding gear can act positively on the carbons, but entirely independent of one another. In order to prevent any pumping when the current is first switched on, an air dashpot is used, which acts only during the striking of the arc, it being thrown out of gear when the feeding begins by means of slots in the connecting link between the core and the dashpot. The lamp is arranged to be self-focussing, so that the arc is always in the same position of the globe whatever length the carbon may be. The posts are of ornamental design, and have been manufactured by Messrs. Allen and Sons.

The gentlemen whose photographs we give herewith have taken active part in the work. When the proposal to light Ayr electrically was first mooted, Mr. James Smith was treasurer of the burgh and convener of the Lighting Committee of the Town Council, and in consequence of his holding the latter position the lion's share of the work naturally fell upon him. Although, as he readily confessed, without any definite knowledge of the work, Mr. Smith at once tackled the duty which was thrust upon him, and by persevering study and investigation soon became conversant with the details of the work projected. On Mr. Smith losing his seat on the Council at a recent election, Bailie Wm. Ure took up the work so ably commenced. Mr. Ure, being an engineer by profession, was able to give valuable advice to the committee when the station was being constructed.

The opening of these new electricity works will be performed on Wednesday, January 8, by Lord Kelvin, with due ceremony, and with the help of Provost H. D. Willock.

CABLE-REPAIRING—A TROPICAL REPAIR.

As the events I am about to relate took place in comparatively recent years, and most of the persons concerned are still living, I think it advisable, in the interest of those persons, to avoid unnecessary candour in the matter of names and localities. "Peace on earth and good will unto men."

The good ship "Express" had been beating her bows deep into southern seas for some months, robbing the bed of the sea of some of its wonderful carpeting and putting down in its place various lengths of brand-new cable, when orders were received to proceed at once to the coast of Bulamaroo to repair a total break which had occurred in the section between Caramba and Matahomo. To have to go to Bulamaroo at all was a misfortune. To make Caramba—a mixture of Muscat and Old Calabar—our headquarters, fell nothing short of a dire calamity. It was not the youngsters. They would have sailed for Guam with Jonah as a shipmate. It was parties with nerves—mainly the skipper.

Taking it generally, it was hard lines. The "Express" was a crack ship, commanded by a high-toned but nevertheless capable seaman. She—and he—had been accustomed to sail in civilised waters, and in the intervals between grappling with minor difficulties to be *fêted* and made much of by good society. The prospect of fever—when one has nerves—serves but to irritate, and the certainty of exchanging My Lords' graceful condescension for the offensive familiarity of a greasy negro population had little in it to soothe. However, we went.

It was, if I remember rightly, on the sixth day out that the Old Man took sick. On the twelfth there was no more champagne. At 11 o'clock that night I was on the upper bridge, tramping it for company with the officer of the watch, when a ghostly figure, clad in a long white garment, made its appearance at the telegraph, and, signalling "full speed astern" to the engine-room, shouted out "Breakers ahead."

It was the skipper, and he asserted that he could smell the land

Poor old chap. Now, I have nothing but pity for him—a gentleman, a first-class seaman, and, as a rule, a very abstemious man. It was due to an unfortunate and perhaps constitutional dread of fever that for the first and, I believe, the last time in his life he drank to excess. At that juncture, however, it seemed far more serious. We were upon an important mission, the latitude was one of frightful storms, and the thought that our lives were under the care of a man who smelt "breakers" when there were 700 fathoms of water beneath us and no land nearer than 500 miles was far from comforting. Eventually we got him to bed.

Arrived at Caramba, we proceeded to land our apparatus and take the necessary tests. The skipper was moderately sober but touchy. He intimated that he should consider it his duty to leave within 24 hours, whether we had located the fault or not, and declined to argue. Fortunately, the cable was brass-taped, and had been crushed flat so that it gave a dead earth, and the tests were simple and conclusive. We located a break 20 miles to the southward, and requested the skipper officially to take the ship to the spot indicated and place a mark buoy. For an hour or so we were busy with our preparations in the testing-room, and then my chief left to inspect the picking-up gear and the fore tank. It was at that moment that things became really lively. We were, it appears, steaming due north instead of due south, and when the skipper was remonstrated with he threw things—chiefly paper-weights — and used language equally hurtful. To put him under restraint was dangerously like mutiny on the high seas, but it had to be done, and with the chief officer in charge we again put into Caramba and telegraphed for instructions. What those instructions were I need not say, but the skipper never again resumed command.

The loss of so experienced a man as Captain ——— naturally made our work more difficult. My chief had to take charge of the deck, while I looked after the electrical arrangements and assisted in checking sights, etc. Not only was our chart wrong and the cable nine miles to the westward of the position laid down, but a submarine landslip had made 500 fathoms difference in the soundings, and, in short, we were all at sea. Of course, we found the cable at last—after breaking the toes off five grapnels—and then had to tear it out of a third of a mile of rock which lay on top of it, repeating the operation some two miles further south. For 36 or more hours we had not a scrap of food, a heavy ground swell made the ship roll her scuppers under water, and when, at five o'clock in the afternoon, we finished the final splice, and stood by to cut away and cheer, somebody said, "Good Lord, it's round the forestay!"

So it was.

It was in the nature of things as they happened that voyage that the skipper should turn up at the moment and witness our discomforture.

If ever a crew were in a blue funk, the crew of the "Express" could have gone one better. To unship a forestay with the ship labouring heavily is an experience. Every moment the foremast threatened to come by the board, but it did not, and by seven o'clock the final splice was safely slipped, and by half-past ten we knew that the repair had been successful. Our homeward trip was equally prolific of incident, but that is "another story."

Utilisation of Natural Gas.—The *Western Electrician* of December 21 describes an electric lighting and power plant put down for the supply of the buildings of the Franciscan Fathers at Oldenburg, Indiana. The peculiarity of the installation is that it is worked by a 25-h.p. Raymond gasoline engine designed to run either with natural gas or gasoline. There is a supply of natural gas from a well close to the building, but it is uncertain, and when it fails provision is made for falling back on gasoline. The dynamo is a Siemens and Halske, wound for 150 volts, and the field rheostat of the machine contains sufficient resistance to allow of running direct on the lights at 110 volts

TO CORRESPONDENTS.

All Rights Reserved. Secretaries and Managers of Companies are invited to furnish Notice of Meetings, Issue of New Shares, Installations, Contracts, and any information connected with Electrical Engineering which may be interesting to our readers. Inventors are informed that any account of their inventions submitted to us will receive our best consideration.

All communications intended for the Editor should be addressed C. H. W. Biggs, *139-140, Salisbury Court, Fleet Street, London, E.C. Anonymous communications will not be noticed.*

TO ADVERTISERS.

Advertisements should be addressed to the Publisher, 139-140, Salisbury Court, Fleet Street, E.C., and should reach him not later than noon of Thursday. **Special Terms** *for a series can be arranged on application.*

"SITUATIONS VACANT" and "WANT PLACES" Advertisements will be charged at THREE WORDS for ONE PENNY with a MINIMUM charge of SIXPENCE.

TO SUBSCRIBERS.

"The Electrical Engineer" *can be had by Order, from any Newsagent in Town or Country, and at the various Railway Stations; or it can, if preferred, be supplied direct from the Office on the following terms:*

	3 months.	6 months.	12 months.
United Kingdom	3s. 3d.	6s. 6d.	13s. 0d.
Other Places	4s. 11d.	9s. 9d.	19s. 6d.

(Post Free, Payable in Advance.)

Cheques, Post Office and Postal Orders for Subscription and Advertisements should be made payable to C. H. W. Biggs, *139-140, Salisbury Court, Fleet Street, London, and be crossed "Union Bank."*

BOUND VOLUMES.

Vol. XV. of new series of "The Electrical Engineer" can be had bound in blue cloth, gilt lettered, price 8s. 6d. Subscribers can have their own copies bound for 2s. 6d., or covers for binding can be obtained, price 2s.

BEST WISHES FOR 1896.

"I held it ever
Virtue and knowledge were endowments greater
Than nobleness and riches: careless heirs
May the two latter darken and expend;
But immortality attends the former,
Making a man a god." Shakspeare.

The year just ended finished up with a brilliant display of war scares. Only one of these scares will concern us here, and that indirectly, inasmuch as it gave rise to certain ludicrous statements in the popular Press. Dalziel's correspondent must be a funny specimen of the *genus homo* ever seeking sensational "copy"—he really ought to be stuffed and put in a glass case in the British Museum as the champion disseminator of "believe-what-you-are-told information." Pour fluids into a sieve and they run through—the sieve has no discrimination, nor has this champion disburser of news. There is a war scare with America, and forthwith this brave champion rushes off on a Sunday, of all days in the week, to Edison to hear what Edison has got to say; and forthwith Edison proceeds to fill the investigator after sensationalism up to the brain with funny tales of the marvels he is going to do, and the newspaper man believes all he is told. *Punch* in its happiest vein could not fool so well. The fact is, this correspondent is either a fool or an ass. Well may the *Daily Graphic* have headed its note, "The American Munchausen." Besides the laughable side of this question, however, there is another. These sensational paragraphs do a real harm which it is impossible to eradicate, and in this direction the English popular Press is as much to blame for inserting such nonsense as the correspondent is to send it. Fancy any fool believing such utter rubbish as the following:

(1) "Water can be made more deadly than bullets. I have invented a machine by which it can be hurled to a great distance, and water charged with 5,000 volts and then dashed on an army would sweep it away like chaff. The only question is how far the water can be thrown?"

In reply to this, we say the statement which has been made before is all moonshine. In the first place, the water cannot be thrown any distance so as to retain its 5,000 volts, and if it could there is nothing more easy than to neutralise its effects. It is enough, however, to know that it is impossible.

(2) "I have also invented cables to be drawn around a besieged city which would deal death to anyone who tried to cross them; and so concealed that they cannot be discovered until too late."

This is bigger rubbish than the other. Edison does not know more about voltage, current, charge, etc., than thousands of other men, but he does know enough to be certain of the fallacy of such a statement. Again, even if he could do what he states, it is just as easy as cutting a piece of thread to stop all his dangers. Our attention has been called to a book which ought to be well known as coming from one of America's most talented and amusing writers—viz., Mark Twain—and if any reader cares to examine "A Yankee at the Court of King Arthur," he will find much of this electric fooling therein. Such a fact does not speak much

Digitized by Google

for either newspaper correspondent, agency, or editor sending, receiving, and accepting fiction of this kind in sober earnest.

(3) "There are also electric chains to be fired into an advancing army. These are of different lengths, and are attached by one end to the wires of a dynamo while the other is placed in a cannon. When these are discharged the air will be filled with chains like great snakes, which would mean death to an advancing host."

Still going from bad to worse. We are inclined to ask this champion correspondent—or Munchausen—if he knows the velocity with which his chain gear would travel, and how he would arrange for his wire to be taken out at that velocity. We would like to know the section of his wire connection, and how he would save its insulation? We would like to know how he knows the other end of his chain will make a good earth connection, and if it did, or, if it did not, what would be the use of it? Are these chains to meander about the air at will? We do not see any danger to the advancing host, but we do see a very definite danger to any insane people who were to try the dodge. These ideas might do as specimens of Sinbad's methods of fighting, but we know a little too much of electricity and magnetism on this side to be terrified by this bold correspondent.

The other schemes mentioned are not electrical, so hardly concern us, but according to our lights have about the same value as those of an electrical character—that is, no value at all.

Up to the present we had credited Edison with a certain amount of genius, though we should not place him so high in the scale of inventors as some of his hero-worshippers do, nor should we place him so low as some of his detractors. If, however, he ever spoke the words attributed to him by this correspondent in any way but fun to stuff a silly man with tales to see how far he would believe them—that is, if he spoke in earnest—our standard of Edison's genius will be lowered to zero point.

It has been our good fortune lately to hear much of Edison, especially in praise of his phonograph. We agree that it is a beautiful piece of apparatus. This telegram of Dalziel's correspondent, however, has caused us to examine into the matter, and as a consequence we find that Edison *may* have obtained his inspiration for this invention from outside his own experiments. "There is nothing new under the sun," says the wise Solomon, and when we find *sound printing* or *phonography* described in 1843, and know how Edison and his collaborateurs ransack the world's literature for ideas, the hint *may* have come from an outside source. The following paragraph relates to the subject, and is of the date 1843:

"We now hear from Germany of the completion there of an invention which about three years since was stated to be in embryo in Manchester, the object of which is to impress the sounds of a speaker's voice on paper or other substance. We know not whether the foreign invention be the same as the Manchester one, but the accounts received of it appear very similar. It is well known that the vibrations communicated to the air by the voice communicate corresponding vibrations to elastic bodies at considerable distances, therefore it is not impossible that the various vibrations may be rendered visible, and made to leave permanent indications. Printing by sound, at all events, does not appear a more extraordinary performance now than painting by light would have appeared five years ago. The latter we have seen successfully accomplished, and we cannot deny that the former may be done. At present, however, we are not acquainted with the *modus operandi*, though we observe, from printed announcements, that a gentleman is about to deliver a lecture on the new art, called *Phonography*, when we may hope to be in possession of the means of taking the whole of a discussion, or of a lecture, home in our pockets for consideration or study at future opportunity. A reporter of this kind would be useful in Parliament, though even then it might sometimes be inconvenient to have the words printed exactly as they are spoken."

Before leaving this distasteful story we would recommend the correspondent referred to to study the following lines:

> "No! Science cannot leave her hill
> And shine with heavenly radiance still:
> Strive not to draw her from the skies,
> But to her bright meridian rise.
> Those who would nobler prospects view,
> And drink the living ether blue,
> Must boldly scale the mountain rude—
> The spell is in the altitude."

During these rumours of wars no doubt we shall hear something about electric guns. According to the following paragraph, the hail of bullets as from a Maxim or a Nordenfelt was achieved by an electric method also in the forties. Who was Mr. Beningfield? If this experiment was so successful, what became of the inventor and his gun? for surely it was in advance of anything else known in 1845. The period—50 years or so ago—is not too remote for someone still living to remember it.

"MR. BENINGFIELD'S ELECTRIC GUN.—Some very interesting experiments have been exhibited in a large plot of ground on the south side of King-street, Westminster, with an electric gun, the invention of Mr. Beningfield, of Jersey. The gun, a barrel for discharging bullets or balls $\frac{5}{8}$in. in diameter, is placed over the body of the machine by which the propelling power is generated, and the whole runs upon a carriage with a pair of wheels weighing altogether half a ton, and calculated to be drawn by one horse at the rate of eight or ten miles an hour: when in position, a third wheel is attached by which it traverses with ease and steadiness. The engineer is enabled to take a true aim, the barrel having a sight similar to a rifle. The barrel is supplied with balls from two chambers, the one fixed and the other movable. The last may be made large enough to contain an immense number of balls. It is calculated that 1,000 balls or more can be discharged in a minute, the volleys being shot in almost continuous or constant succession, the stationary chamber supplying the barrel. The experiments fully carried out all that the inventor professed to do. The bullets were driven through a thick plank, and afterwards completely flattened on an iron target. Those directed against the target without the intervention of the planking were literally beaten to atoms, and in a manner plastered upon boards placed on the sides of the target, which received the fragments as they flew off at angles from the iron. The force far exceeded what can be produced by any military engine of equal calibre in which gunpowder is employed as the propelling power. A 3in. board at 20 yards distance was completely shattered through with the bullets, as if the centre-bit and drill of a carpenter

Digitized by Google

had been employed, and the rapidity and precision of aim was extraordinary. For clearing a breach or sweeping a force such an engine must be most tremendously destructive. The cost of keeping this gun in repair and of using it is stated to be very much beneath the cost which must be employed to bring into operation any other equally efficacious mode of discharging thousands of balls. The invention is not secured by patent, and therefore the inventor did not communicate the secret of the construction of his instrument or the nature of the power employed. It was avowed, however, that the propelling power is produced, not by steam, but by the application of gases exploded by galvanic electricity."

Men in those days were quite as energetic as men are in these days. Progress has been great in numbers, and hence in demand and volume of business, but they then looked ahead, even as we now look ahead. Telegraphs were few; this application of electricity was in its infancy. There were no cables, yet men discussed the time when the uttermost parts of the earth should be telegraphically connected. How soon after telegraphy was an actuality did the idea of cable communication commend itself to those interested we do not know, but it must have been in very early days. A paragraph in 1845 reads thus:

"A writer in the *New York Tribune* suggests a plan for bringing Old England within a speaking distance. He proposes to run a copper wire, well covered, and as large as a pipe stem, from Nova Scotia to the coast of Ireland. This, as is thought, may be accomplished by winding the wire upon reels, and arranging it on board a steamer so as to be reeled off as fast as the boat goes, and dropped the whole width of the Atlantic. The writer says: 'Its gravity would sink to the depth where water was so dense as to be of equal gravity, and, of course, beyond the reach of any kind of collision. Beginning and ending on a bold shore, beyond the reach of anchors, it would be out of harm's way, and exposed but to two kinds of accidents—viz., from separation by its own weight and the loss of the coating, from which the metal must be protected. The steamer "Great Britain" would carry more wire of this size than would extend to Europe, and its cost would, I think, be less than a million of dollars.'"

We might give a number of references to the capabilities of electric applications long anterior to these, but it would only show that we have what our forefathers hoped for, and this should lead us to infer that what we have will be superseded by our descendants.

Water Power.—Most of us get into a slovenly habit of writing, knowing perfectly well that only the few who are blind from the fact that they will not see are those who mistake what is written. Thus electricity is not electrical energy any more than mechanical energy is iron; but we are continually writing electricity for electrical energy, and nobody a whit the worse. Future controversialists and precise critics will no doubt quote sentences against us as evidence of lack of knowledge or precision; but that won't hurt us, and it may please them. We can never get over Thursday and Friday without being told of our weekly weakly sins. Then if we make a slip of a decimal or an adjective, our readers will have to generalise by using "about" as the result of the following calculation. The heat energy of the sun is the source from which we mostly draw our utilisable mechanical energies. Part of this heat energy is expended in vaporising and lifting water, and it is calculated that in a year 31,000 cubic miles of water are so vaporised, of which 13,000 cubic miles run back by rivers into the ocean. This water falls through a height equal to the mean level of the land, which may be taken for the whole world at about 1,000ft. The total water volume shed over England and Wales is about 20 cubic miles per annum, and we may assume the mean level of land at about 400ft. Thus in England and Wales 20 cubic miles of water fall 400ft. each year. A cubic foot of water weighs 62½lb., therefore a cubic mile of water will weigh 9,199,872,000,000lb., and falling 400ft. gives us 3,679,948,800,000,000 foot-pounds available from each cubic mile of water so falling. Then if 20 cubic miles so fall we have no less than 73,598,976,000,000,000 foot-pounds available, or about 2,230,272,000,000 h.p. per annum. Of course only a small fraction of this can be utilised, but for the sake of having the figures before us we have ventured to give what may be called the annual quantity of water on tap. It will be seen that a vast store of energy is now going to waste which will certainly be to some extent utilised when coal gets scarcer and therefore dearer.

THE ELECTRIC CONSTRUCTION COMPANY report an unprecedented amount of work during the past year. Enquiries and orders for all classes of machinery have been very numerous. Great progress has been made in the design and efficiency of their specialities in dynamos, motors, continuous-current transformers, alternators, and converters, arc lamps, switches, etc. No catalogues have been issued and better prices prevail. Among special contracts may be enumerated a supply of generating plant for the Corporations of Wolverhampton, Stafford, Manchester, and Halifax; the Liverpool, Birmingham, Chelsea, Oxford, Crystal Palace, and Clerkenwell Electric Supply Companies; Vestry of St. Pancras, etc. The Madras tramways have also been successfully put into operation. Work in hand includes 500-h.p. dynamo for the War Office, 300-kilowatt steam alternator for Halifax, motor equipments for the Liverpool Overhead Railway extension, the electrical equipment of Hartlepool tramways, and other important orders representing at least six months' work. The number of employés is steadily increasing, and important additions to the premises and machinery are being provided to cope with the great accession of business.

P. R. JACKSON AND CO. (Manchester) say that, although their new dynamo factory has only been in working order for about five months, they are full up with work, and have more than 30 dynamos in hand at the present time for customers. They have also a large electric hauling plant for a colliery and two electrically-driven centrifugal pumps, and complete electric plant for transmission of power in printing and bleaching works. The prospects for 1896 are extremely bright; there is not only every possible chance of being extremely busy in the electrical department, which they are arranging to extend, but they are extremely busy throughout the whole of the works, many machines, particularly the heavy machines, running night and day, Sunday included. The company say their new dynamos have been remarkably well received.

Digitized by Google

RANSOMES, SIMS, AND JEFFERIES.—This firm report that they have been very busy during the past 12 months. Besides their standard engine and boiler trade, and other plants for electric lighting, a large business has been done by this firm in the "open-type" high-speed vertical engine, specially designed for driving dynamos, which they introduced rather more than two years ago. Messrs. Ransomes have had numerous repeat orders from early purchasers, and the engines have steadily progressed in the favour of electrical engineers and other users. The patent expansion-shaft governor, introduced by this firm about the same time as the engines, has given particular satisfaction on account of its absolute reliability and the extreme regularity of speed which it ensures. Messrs. Ransomes guarantee that the variation between full load and no load of an engine fitted with this governor shall not exceed 3 per cent., and they have figures taken by independent electricians showing a variation amounting to only half this. More than a dozen of the engines supplied during the past year have been fitted with the patent expansion-shaft governor, but in cases where the extra cost of this apparatus is objected to Messrs. Ransomes fit their engines with an improved governor acting upon a throttle-valve. In the design of this improved throttle-valve governor the objectionable governor driving belt is dispensed with, the governor weights being mounted directly upon the crank-shaft. Among the engines completed during the last 12 months, particular mention may be made of four compound vertical engines, with cylinders 11in. and 18in. diameter by 10in. stroke, revolutions 320, coupled direct to dynamos for large electric light installations in Scotland; a compound vertical engine, with cylinders 6½in. and 11in. diameter by 7in. stroke, revolutions 350, for driving the dynamo in connection with the Hermite deodorising process at the new Marsh sewage works of the Ipswich Corporation; and a double-cylinder vertical engine, with cylinders 11½in. diameter by 9in. stroke, revolutions 250, for electric lighting in a North Country cotton mill. A large number of small single-cylinder engines to be used in connection with ship-lighting plants have been supplied to various electrical contractors, and Messrs. Ransomes are now laying down three compound high-speed engines for driving part of their own factory. They have a considerable number of orders in hand, and prospects for the coming year are favourable.

THE EPSTEIN COMPANY.—The year 1895 has justified the expectations which the directors of the Epstein Electric Accumulator Company had entertained, based upon the steadily growing favour with which leading firms and many eminent electricians looked on these cells and the rapidly increasing demand for them owing to the unqualified satisfaction they had given in every instance. The new and splendidly equipped works at Milton, Staffs, were inaugurated towards the close of 1894, and manufacture on a much extended scale was commenced in January, 1895, and maintained without slackening off throughout the year. A goodly number of central stations has during that period been added to those who had installed Epstein batteries in previous years already, and many corporations and supply companies have rejuvenated their existing batteries of other types by replacing the worn-out parts with Epstein plates, a process for which these latter are specially well adapted. No less successful has this company been in securing the goodwill of many important firms of contractors in all parts of the United Kingdom, the Colonies, and abroad, the net result of the year's work being an increase of over 100 per cent. compared with the previous year. Such eminently satisfactory results are convincing proofs of the high reputation which Epstein accumulators have established for themselves. Developments in traction batteries of far-reaching importance and almost universal interest have now, after years of patient investigation and the most careful tests, reached that degree of perfection when they can be confidently supplied for the public service. While retaining all those parts liable to deterioration which during the past years have given so good an account of themselves, the entire weight of the cells has been reduced by no less than 70 per cent. To achieve this without affecting strength and durability has been a problem of great difficulty, yet, the company are glad to announce, it has found its solution at last, and it may be expected that the great and burning question of propulsion by means of batteries has entered into a practical stage.

THE ELECTRICAL COMPANY.—The Electrical Company, Limited, of 122 and 124, Charing Cross-road, W.C., have had a large share of the increased trade during the past year of development of the electrical industry. The special department opened by this firm about two years ago for the sale of dynamos and motors, and for the installation of transmission of power and lighting plants, has proved a perfect success, a large number of their machines having been installed all over the country and the Colonies, which are giving the fullest satisfaction. A point of great interest is that the Electrical Company, Limited, construct (contrary to the usual type of bipolar dynamos and motors) such machines only up to 100 amperes, of the well-known iron-clad type. Above 100 amperes for any output their dynamos and motors have four or more poles, the frame of these machines being also of one solid piece of steel. Thus the stray field is reduced to almost nil, with corresponding increase of efficiency. Owing to the great expansion of their business in this direction, the Electrical Company, Limited, have been compelled to make arrangements at their factory for doubling the output of machines, and they are therefore now in a position to ensure the most prompt delivery in the course of the New Year.

MELDRUM BROS. have fitted a large number of their furnaces to electric supply stations during the year. At Blackburn, six furnaces; Stafford, six furnaces; Newport (Mon.), eight furnaces; Bournemouth, seven large Babcock and Wilcox; Westminster, 10 furnaces; Islington, 10 furnaces. Some of these are also fitted with their patent silencing apparatus (as fully described and illustrated in our issue of October 11 last).

THE LIVERPOOL ELECTRIC SUPPLY COMPANY state that the number of lamps supplied from their stations during the year has increased to a total equivalent to 40,000 16-c.p. lamps. In addition to installations carried out by the company in connection with their supply system, they have completed contracts for numerous private installations, amongst which may be mentioned one of 500 lights for the Liverpool Rubber Company, Limited. The company are now engaged in lighting the Liverpool landing-stage for the Mersey Docks and Harbour Board.

JOHN SPENCER says that "during the past year we have been fairly busy with wrought-iron tubes used as underground conduits for wires and cables, also in socket and spigot pipes for the same purpose for various electric light and telephone companies.

Digitized by Google

Several orders executed and in hand for large and small steam-mains for generating stations, together with the usual feed and exhaust pipes; also a moderate amount of orders for iron arc lamp poles, iron telegraph and telephone poles, both tapered and parallel, for use in connection with electrical mining work, tramway, telegraphic, telephonic, and fire-alarm systems. We have just put down an 'up-to-date' plant for best quality solid-drawn weldless steel tubes, of which we shall make a speciality, and we anticipate a big trade during the coming year."

ABERDEEN.—Mr. A. S. Blackman, the Corporation electrical engineer, writes: "The 'thorn in the flesh' of every central-station engineer is undoubtedly the often discussed but as yet never attained day load, and until matters are improved in this respect it can hardly be expected that anything very far in advance of present station costs will be achieved. Improvements in the matter of 'beating record' will no doubt appear from time to time as our station outputs grow; but for any radical improvement in costs, it is the day load we have to look to, and which seems a far more hopeful field than the small improvements we can reasonably expect to get in the way of increased efficiencies. In manufacturing towns supplied by the continuous-current system, and where there are numerous isolated plants, in factories, large hotels, etc., it has often occurred to the writer that great benefit would accrue to all parties concerned if supply companies and corporations would adopt a special low tariff for a day supply for the purpose of charging batteries on the large consumers' premises, and let those who wish take their supply during the daytime and store for themselves. I am aware that this is no new idea, and would not advocate it to in any way supersede the direct supply, but only to meet the requirements of large establishments who would otherwise lay down their own plant. Of course, these private batteries could be charged from the ordinary network, but the consumers' lamps would necessarily be of lower voltage than the supply, and the regulating cells might be paralleled for charging purposes. Very little skilled labour would be required by the consumer, and he would dispense with moving machinery. In the case of municipal undertakings, of course, we have electric tramways to look forward to, but in this we have the very awkward element of the two loads overlapping at the worst possible time, for the top-load period is probably the busiest time of the whole day with the tramways. It may be contended that the charging of private batteries is not likely to be a source of any very great profit to many undertakings, owing to the few isolated plants we have; but, on the other hand, there are many places where this would not apply. In Aberdeen, for instance, where we have turned out for the last year, roughly speaking, 160,000 units, had we also supplied all the private plants within reach, this output would have been nearly doubled, and the one half of our total output supplied during the daytime, with our present machinery and capital expenditure, or perhaps a very small addition to the latter for mains extension: and I have no doubt that Aberdeen is by no means an isolated case."

Telegraphic Extension in the Gulf of Aden.—The Berne *Journal Télégraphique* states that the French cable from Obock to Jibouti is now available for use by the public at a provisional tariff of 20 centimes a word. Jibouti is situated at the southern extremity of Tajura Bay.

CORRESPONDENCE.

"One man's word is no man's word,
Justice needs that both be heard."

THE INSTITUTION OF ELECTRICAL ENGINEERS.

SIR,—If I rightly understand the feeling of the large section of members of the Institution who, with its best interests at heart, are of opinion that the time has now arrived when some changes should be carried into effect, their desires may be comprised under two principal heads.

They are anxious, firstly, that the constitution and the manner of election of the Council should be so altered as to render the Council more truly representative of those who are actually doing the electrical work of the present day, more in touch with their requirements, more conscious of their desires and aspirations, more amenable to their wishes; secondly, that the standard of qualification required for full membership of the Institution should be raised, so that such membership should be a real and not, as at present, a practically nominal distinction.

With a view to arriving at a satisfactory solution of these problems, I beg to submit for consideration the following suggestions, which are, of course, only in outline, and are capable in some cases of considerable modification in detail:

(1) Some curtailment of the growing preponderance of power at present vested in the permanent members of the Council as distinguished from the elective members.

(2) An increase in the number of elective members of Council so that all branches of the profession shall be more adequately represented.

(3) A large number of members of Council to retire annually so as to allow of the introduction of more fresh blood every year.

(4) Greater facilities to be given for country members serving on the Council, it being understood that such country members of Council need not give such constant attendance at the Council meetings as is expected of members resident in London.

(5) A much longer interval of time to elapse between the publication of the Council's nominations for new members of the Council and the date on which the ballot is held.

(6) The list of nominations to be published at least one month before the issue of the ballot papers.

(7) The ordinary members to be given an opportunity of adding names to the Council's nomination list, and names so added by ordinary members to be printed on the official ballot papers in such a manner as to be indistinguishable from those nominated by the Council.

(8) The evening devoted to the annual general meeting to be reserved entirely for the necessary formal business, and for discussion on any matters pertinent to the general affairs and welfare of the Institution.

(9) Some alterations to be made in the constitution of the Institution, whereby for the future no one shall be qualified for election as a full member who is not actively engaged as a practising electrical engineer or electrician, a new class being created—as in the case of the Institution of Civil Engineers—for those who desire to belong to the Institution, and whose association with the Institution may be of advantage to the latter, but who are not qualified for full membership.

None of the above suggestions can be said to be in any way revolutionary, one and all of them being taken from the regulations in force in other engineering societies older and more experienced than our own.

I believe that some changes in the direction indicated could not fail to be salutary, and would greatly increase the prestige, usefulness, and harmony of the Institution as a whole.—Yours, etc.,

A. A. C. SWINTON.

London, S.W., December 31, 1895.

SIR,—We are now going through a time which remotely resembles the agitation which has sprung up in the Transvaal, without, of course, the racial difficulties. A cure may be found in both cases by a large and liberal measure of reform.

Our constitution, it is said, does not provide for sufficient representation of the body politic. My competence to

Digitized by Google

write on the subject may or may not lie in the fact that I am the survivor of the two founders of the Society of Telegraph Engineers, now the Institution of Electrical Engineers, and consequently the eldest (not the oldest) living member, having sat in the Council, either as a member, treasurer, or past-president, and been a constant attendant at its meetings since it first met in May, 1871.

As a member of the Institution, in which capacity I venture to address you, I am very much in accord with the general spirit of the various correspondents in the electrical journals—namely, that a radical alteration is necessary in the organisation of our representation. I believe we should not be afraid to cast ourselves free, if we find it necessary, from the shackles of tradition and custom inherited from other similar societies or institutions, and that there is plenty of scope for originality, the effect of which would be to bear useful fruit in welding together the interests of the various branches of the professions which form our constituency, thereby increasing the usefulness of the Institution, and giving it cohesion which will last for a long time to come.

The completion of 25 years of our life seems an appropriate time to have the subject exhaustively thrashed out, and I, personally, shall be most willing to aid any such movement that may be originated by a sufficient number of our members and associates, in order that, if necessary, our charter, which has been now in force for 11 or 12 years, may be altered to suit present and possible future requirements, which we understand far better now than we did even 12 years ago.

If I may be allowed to suggest, in spite of the too probable "pooh-poohs" of the conservative and "save-trouble" interests, the deliberations of any general committee appointed to consider the subject may with advantage deal with the possibility of the establishment of a "second chamber" in the governing body, which shall take a share separately and conjointly in dealing with many of the questions now dealt with by the existing Council alone.

I am myself in favour of local honorary secretaries and committees of members and associates throughout the United Kingdom; of larger and more effective representation of the great body of associates; and of limiting the use of the occasional vote of past-presidents who have practically given up attending the meetings of our governing body.—Yours, etc., C. E. WEBBER.

THE BLOCK TELEGRAPH SYSTEM.

BY J. PIGG.

The occasional occurrence of lamentable accidents, involving loss of life and destruction of property, on our railways reveals, under the rigid enquiries to which they are subjected, the fact that the system of block signalling on which we so implicitly rely is liable to break down under certain circumstances. Since the "block" system is entirely worked by electrical apparatus, an examination of some of the weak points in the system will not be out of place in the columns of a leading electrical journal, and a discussion of any points observed in practical working may result in suggestions for improvement.

It is a trite observation that when the cause of a failure has been ascertained half the remedy has been discovered, and it is therefore proposed in this article to show the most salient points as emphasised by recent events, and to point out as far as possible some remedies, having regard to the fact that improvements in this direction, as in most others, are necessarily the result of experience, and therefore of slow and gradual growth. The large amount of capital already sunk in the installation of signalling apparatus places an effectual check on revolutionary changes, to say nothing of the confusion inevitable from a total change in the methods of working.

Theoretically, the "block" system in use for working traffic on English railways is perfect. If by any means it is possible to preserve a distance, however small, between successive trains on the same line of rails, no disadvantage other than delay will follow. The primary function of all "block" working is to ensure the preservation of a certain distance, varying in different places, between two successive trains without unnecessary delay. This last condition is primarily dependent upon the arrangement of traffic, and may be dismissed from further consideration in connection with "block" working proper, which consists solely in passing trains safely through the different sections as they arrive.

The electrical apparatus provided in each "block" cabin has several functions, the chief of which are the indicating of the condition of the line, and the transference of signals indicating the description of the trains and asking and giving permission for these trains to pass through the section. There is not at present anything automatic in the general working of the "block" system—*i.e.*, the passage of trains through any section does not, *per se*, actuate any apparatus to protect itself, or indicate its presence to anyone concerned, and the electrical apparatus is therefore entirely dependent upon the actions of the signalmen being in accord with the actual state of the line. The actual passage of the trains is of course controlled by the outside mechanical signals worked by the signalman, but these are worked in accordance with the indications or signals received independently on the "block" instruments. The actual methods of signalling are too well known to require description.

An examination of the regulations, code of signals, and their order, together with the actual working of the instruments, shows that the important point in a "block" section is evidently considered to be at the receiving end—that is to say, that end of the section towards which the train is travelling. The signalman at the receiving end is responsible for the entrance of a train into the section by his acceptance of the "be ready" signal. He controls the indications of the "block" apparatus, and it is he who certifies that the whole of the train has passed under his protection by giving the "line clear" signal. Shortly stated, it may be said that every "block" section is controlled by the man at the receiving end, and that the man at the sending end acts simply as a more advantageously situated assistant or look-out man, and informs him when trains are ready to enter the section, but acts strictly on his instructions in allowing them to do so.

A closer examination into the methods of "block" working shows that it depends for its safety upon the absolute accuracy with which several men can perform their different duties. A slight dereliction or neglect of duty on the part of the driver of a train or the signalman at either end of the section may be followed by serious results. The driver MUST act in accordance with the mechanical signals exhibited. The signalman at the sending end of the section MUST exhibit such signals as are in accordance with the condition of the line as shown by the "block" instrument. The signalman at the receiving end MUST ascertain that the line is clear before giving permission for a train to proceed towards him. Instances are not rare where drivers HAVE run past signals at danger through fog or other causes; where a signalman HAS sent a train into a section without the necessary permission; and where a signalman has cleared the line and taken another train into the section without having first ascertained that the line was clear.

Hence it becomes advisable to consider whether, notwithstanding the degree of perfection of the system when properly worked, it is desirable to supplement the apparatus already in use in such a way as to minimise the chance of error on the part of those engaged in the work. That such checks are desirable there can be no reasonable doubt, and many suggestions of various kinds and different degrees of merit have been made with but meagre results up to the present so far as adoption for practical and continuous work is concerned.

The mechanical signals are of the greatest importance to railway working, but are of slight interest to electricians, except in so far as they are concerned in "repeating" them. Mechanical signals, however, are placed, or should be, in such positions as enable them to be seen by drivers for their guidance, and the practice of fixing signal on high posts, or at much greater elevations than the position of the drivers is, to be deprecated on account of the difficulty of seeing these signals in foggy weather. Any advantage gained by the signals being visible at a greater distance in clear

Digitized by Google

weather is more than counterbalanced by the difficulty experienced in seeing the signals at all during fog, when the necessity for seeing them is much enhanced by the difficulty drivers experience in "localising" themselves. The system of fog signalling now in use is antiquated and expensive, and much valuable time may be lost in calling out and equipping men for this special and uncertain work. The ideal system of fog signalling is one that indicates, *on the engine*, that a signal which is being approached is at danger. Such indication should be visual and not aural, as at present, and it should be under the control of the driver, and be capable of being brought into use by him at any moment.

Any additions to the electrical apparatus in use for "block" working should conform to the following requirements: It should be cheap and simple, and not readily put out of order. It must involve no change in the character of the apparatus already in use, or give additional work to the signalman, and it must not interfere with the regulations of the service or the signals which it is necessary to send on the instruments for the working of the traffic. It must not be forgotten that the duties at the two ends of the section are by no means the same, or of the same importance, and that experience shows that apparatus designed for universal application or to serve a number of purposes nearly always fails to give complete satisfaction owing to its complexity. The apparatus devised should not, therefore, necessarily be all in one case—the simpler the duties of any instrument are the more likely it is to perform them efficiently.

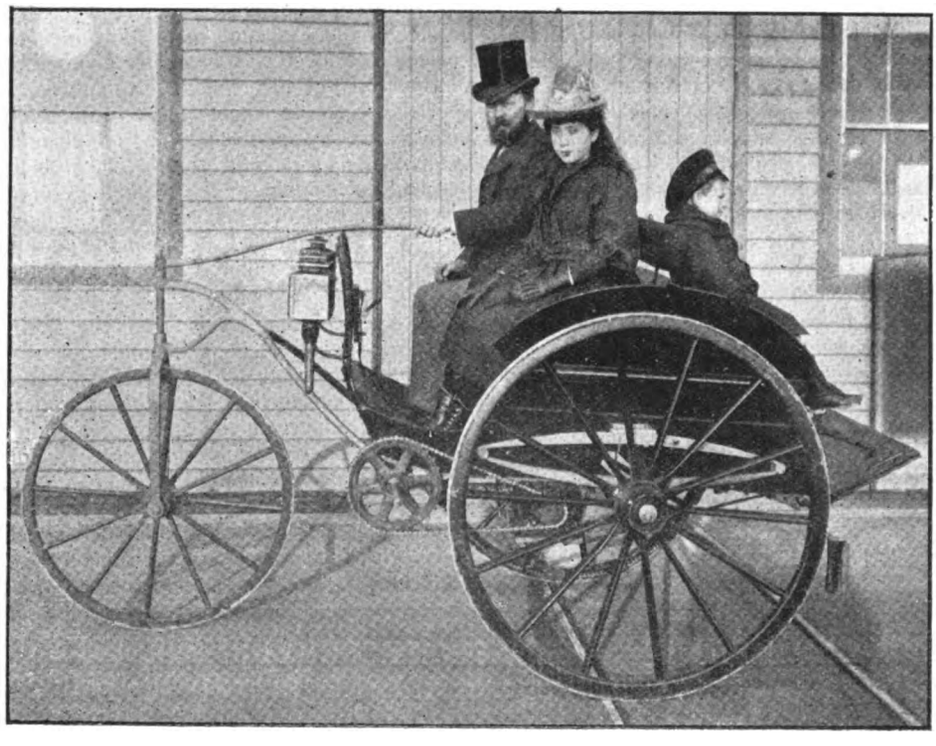
An apparatus which would appear to best fulfil the conditions required for the receiving end of the section would be such as would enable the "block" instruments to be locked in the "train on line" position, with the concurrence of both the signalmen, after the usual signals had been sent, the lock being so arranged that it would be released by the passage of the train over some point at the receiving end of the section. Such an arrangement would not be desirable as a means of "clearing" the line, but would be admirable as a check against the signalman performing this action before the train was actually in the proper position for him to do so. If neither signalman was able to clear the line until the train had passed a certain point near the receiving end of the section, where it must necessarily have passed under the eye of the signalman, then, with the exercise of judgment in selecting the point of release, such an accident as would result from a signalman clearing the line, and accepting another train from the rear, under the impression that the line was clear, could not occur. The danger of accidents occurring from this cause is not imaginary; such accidents have already happened, and there is not the slightest reason why, given an absent-minded man, they should not recur, more especially where the train standing is a short one and is at the "advance" signal.

It has already been pointed out that the chief danger arising at the sending end of the section, so far as the signalman is concerned, consists in his ability to send a train into the section, under misapprehension, contrary to the wishes of the man at the receiving end. The simplest method of preventing such a mistake would be to lock the "advance" signal by the "block" instrument for all positions of the latter except "line clear."

Such arrangements as those outlined in the barest possible manner would do much to enhance the safety of block working by providing valuable checks on the actions of those responsible for the working of the apparatus, and there seems no reason to suppose that suitable apparatus could not be provided at a reasonable cost.

MOTOR CARRIAGES.

As self-propelled vehicles are now receiving considerable attention, the time being near at hand when the present restrictions to their use on the public roads will be removed,



we give an illustration of a vehicle designed by Mr. Magnus Volk, of Brighton, propelled by a 2-h.p. motor. Although at the present moment electricity cannot compete with paraffin or benzoline when used to propel a road carriage, as far as regards distance, run, and cost, the electric carriage has a distinct field of its own, for there are always persons who are willing to pay a higher price if a better or more convenient article is to be obtained.

For runs up to 20 or 25 miles, for town and park use, the electrically-propelled vehicle is unrivalled. It is free from dirt, vibration, smell, and noise; is ready instantly, and can be used by ladies with the greatest comfort, and in these times the charging of the accumulators can be carried out with the greatest facility by attachment to the supply mains whilst standing in the coach-house.

Apropos of this, as accumulators could often be used for many purposes, an automatic charger that could be inserted in the main circuit so as to regulate the charging current, and automatically cut off when the cells are fully charged, would be a great desideratum. A proper number of cells would, of course, be used suitable for charging from the supply mains.

TECHNICAL EDUCATION.

BY H. H. SIMMONS, A.I.E.E.

There are two fundamental questions regarding technical education which are most difficult to answer, and are consequently most vexed. The one is, What should be the duration of the purely theoretical training? and the other, When should this training be given? To give an arbitrary answer to either of these questions is surely impossible, for it must be affected both by the natural capabilities of the individual and the course he has mentally mapped out for himself. Apart, however, from such variable considerations as these, there are, it seems, two sides to both questions—that is to say, it is an open question how best to give a good all-round training to a man of average capabilities.

The ideal method is an elastic combination of theory and practice, including manual training, and such that it leaves the learner free to attack any difficulty which presents itself in either direction, care being taken to maintain the balance so that the bearing of practical on theoretical and theoretical on practical considerations be duly and simultaneously kept in view—an ideal almost impossible of attainment, except perhaps to the millionaire. This ideal is, however, hinted at, and an apologetic attempt to reach it is made in most technical colleges by the maintenance of a more or less sleepy workshop, where the machine tools are of an excellent kind, very much underworked and require little or no exercise of ingenuity or skill on the part of the operator. The expenditure on these shops is necessarily very large both in prime cost and upkeep, and it is hardly fair to look for improvements which would add largely to the cost of working.

It is, of course, out of the question to hope for manual skill of any high order from these shops, but they might surely be worked so as to be much more efficient in acquainting the students with ordinary workshop methods. Broadly speaking, one of three courses is now usually followed. College is made to follow immediately upon school, and the workshop or drawing office, or both, of some commercial undertaking supplies the further practical training without which no budding engineer begins to be worth his salt. Or this order is reversed; or, thirdly, pupilage supplies the practical and evening classes the theoretical training.

The second course is, perhaps, the best as a rule, for if a man be fit to become an engineer at all he cannot fail to observe and to seek the why and wherefore of what he sees, and this renders him peculiarly receptive toward the information subsequently to be gained at a college.

There is, however, a fourth method which must commend itself to all practical men, and which is being more and more largely followed—it is also a nearer approach to the ideal. On leaving school the youth of 17 or so enters a workshop as a boy at from 4s. to 6s. a week, and supplements this experience by evening study and technical training. In the workshop, workshop methods and current practice become familiar, while manual dexterity, not to be despised, though of very secondary importance, is also acquired: from private reading, theory may, in these days of innumerable books on every subject, be slowly but surely learned, but only at the cost, it is true, of patient, laborious study. Technical training, an entirely distinct thing, as has often been pointed out, can only be gained by attendance at some technical institute, or by years and years of painful and costly experience. It is this training which is needed to enable the engineer to combine theory and practice, and to truly estimate the relative importance of the considerations urged on either side for the solution of the problems he has to solve.

The advantage of this fourth course is that a widening range of acquaintance with both practical and theoretical considerations and their relative importance is acquired, and the risk of either's preponderating unduly is reduced, but against this must be set off the extremely hard work entailed, which requires a tireless patience and perseverance in spite of the slow apparent progress made. We are living, however, in an age of hard work, particularly of hard mental work, and the man whose constitution, whose funds, whose patience, and whose general education are sufficient, will find that this road will find him, broadly speaking, more competent, self-reliant, and generally better fit to take a responsible post than his brethren who have chosen the other roads, but he may have to wait till he is between 30 and 35 before his advantage becomes apparent.

ELECTRICITY IN MINING.

BY SYDNEY F. WALKER.

Enormous as have been the advances made in the development of electricity in every branch of business, probably in none has it been greater during the last 20 years than in mining.

It is now very nearly 20 years since the present writer took up the subject. At that time the telephone was not in existence, the electric light undreamt of for mines, and electric signals had a bad name. But the advent of the telephone in 1878 changed all that. Though the telephone in those days was correctly described as a scientific toy, the "boom" with which it was introduced created an interest in other electrical apparatus, and so electric signals again came to the fore. Now the number of mines in the kingdom in which they are not used is very small indeed, their great utility having long since commended them to the minds of mining engineers.

About this time, too, the electric light began also to make a fresh start. A few years before the writer had given up his position as electrician to the company who owned the Gramme patents, because the company had got itself into Chancery, and there seemed no chance of doing any work or getting any pay for it; but he had kept his eye constantly on the matter, and when the British Electric Light Company began to push the Gramme machine for electric lighting he arranged to work with them. About this time Mr. Hollingshead brought the "Lontin" apparatus over to the Gaiety Theatre, from which it was subsequently taken to the Gunner Colliery in the Rhondda Valley, but was not successful. Then appeared the "Brush" system, and immediately after the "Brockie" commutating lamp. In the latter part of 1879 and early part of 1880 the writer ran a temporary installation, consisting of two arc lamps and an A Gramme dynamo, at the Nunnery Colliery Company's coaling screens just outside Sheffield. This was followed by installations of five Brockie commutating arc lamps at the Gunner Colliery in the Rhondda, and at the Mardy Colliery in the Rhondda Fach valleys. These, he believes, were the first successful installations of electric lights at any colliery. At Cymmer the dynamo was driven by the workshop engine, at Mardy by the fan engine. The Cymmer lights were abandoned about two years later, and the colliery is still without electric light, one of the few remaining in the Rhondda. As there is an abundant supply of natural gas coming out of one of the pits which is cheaply adapted to illuminating purposes, immediately one of the periodic down waves in the coal trade appeared the electric light was given up. The Mardy dynamos worked on till quite recently, though the Brockie commutating lamps were abandoned as soon as the Sunbeam lamp became practicable.

Soon after this came the incandescent lamp. Risca Colliery, Monmouthshire, after its explosion, and Earnoche Colliery, in Scotland, adopted it at once, and almost simultaneously. At both, Gramme machines of the old A and B type were used, which have since been displaced. Risca still has the electric light, but has gone no farther. Earnoche has kept up its advanced position, and has now a hauling and pumping plant. Shortly after this the writer fixed a small plant of 40 lamps underground at Harris Navigation Colliery, the engine being driven by compressed air, this being the only method then available. The plant in a modified form is still working, as was also till very recently a plant which he fixed on the surface at the same colliery just previously.

After this time comes a period of continuous advance Colliery after colliery in all parts of the country have adopted the electric light, because it has been found to be cheaper, safer, and more convenient, even oil lamps not being able to compete with it. One plan is adopted in nearly every case. A dynamo and engine are placed on the bank in some convenient position, usually where another engine is at work, and cables are led from it to all parts of the colliery, above and below ground, often also to the houses of the colliery officials.

Digitized by Google

The improvements effected in the dynamo since the expiration of the Gramme patent, the continuous education of colliery officials which has been constantly going on, and in which the writer claims to have had a large share, with the continuous improvement in the incandescent lamp, have all tended to effect this. The arc lamp has practically disappeared from mining work. The advent of the large incandescent lamp killed it. While the electric light in mines was still in a very infantile stage, Mr. B. Brain, at Trafalgar Colliery, in the Forest of Dean, had laid down a small electric pumping plant, consisting of an A Gramme series-wound dynamo as generator and a small Siemens series-wound dynamo as motor, and this plant continued to work until it was displaced by a larger plant a few years back. Years passed before other mines followed suit; and when it was taken up, it made progress very slowly. At first it was only used for dip workings, and is even now used more for that class of work than for any other. When the coal measures incline downwards from the shaft, as many do, much of the water present finds its way into the lower workings, and the electrically-driven pump, with its cables coiled on a drum, easily run out as the workings move forward, has proved very convenient and economical. Several large electric plants, pumping water from the neighbourhood of the pit bottom to the surface, have also been put down in various parts of the country. One such plant in particular, in Monmouthshire, is stated to have turned out very economical, the whole of the water now being got out of the colliery in a few hours, where previously three steam-pumps worked day and night to do the same. It is fair, however, in this case to mention that at least a portion of the economy effected is due to the system adopted of draining all the water into one large lodge-room, or tank, from which the electric pump lifts it to the surface. On the other hand, it is stated that compressed air could not have done the work satisfactorily; and in another somewhat similar case an eminent mining engineer told the writer that he had tested the efficiency of pumping by steam from the bottom of a shaft as against pumping by electric transmission, and he found that the loss by condensation more than overbalanced the losses by conversion and conduction in the electric system.

On a small scale, too, electricity is being used for drilling the flanges of steam-pipes, etc., the convenient electric drill being taken to the work, instead of its being necessary to take the work to the drill. It is also being used still, on a small scale, for directing currents of air through particular portions of the mine, a small electric motor, with fan attached, being easily and quickly placed in any required position. The writer believes that something of this kind would be very useful after explosions in mines, to direct currents of air easily and quickly in any direction that exploring parties may take. Within the last few years hauling and winding plants have been installed in a few mines in different parts of the country, and electric rock-drilling and coal-cutting machines have also been introduced into some of the Yorkshire collieries, and into some of the Cleveland iron ore mines.

Progress in all these is necessarily slow. Mine-owners are afraid that the sparks at the commutators of electric motors may fire gas. As it is now perfectly practicable to produce an electric motor that is not only theoretically sparkless, but that is absolutely sparkless under all conditions except those produced by extraordinary accidents, and as it has also been shown that the spark of the ordinary motor does not fire the gaseous mixture in a mine, there is every hope that these fears will gradually cease to be. The writer claims to have been one of the first to show, in a practical and scientific way, that nothing was to be feared from this cause; that it was not a spark *per se* which would ignite gas, but a spark of a certain energy—viz., about 20 watts. The writer's experiments were made with ordinary coal gas, but he understands that recent experiments by Prof. Vivian Lewes show the gaseous mixture met with in coal mines to be much less inflammable than ordinary coal gas. It is even claimed, on the authority of some experiments made in Germany, that the spark which passes between the broken ends of a live cable will not fire the gaseous mixture in a coal mine, as it does not continue for a sufficiently long period.

In the matter of the construction of cables for use with electric light and power currents in a mine, the writer is at variance with the general practice. His view is that it is unwise to protect the cable by an outer conductor, whether armour or lead, as you run great risk of damaging the insulation; that the money spent on the outer metal protector would be much more serviceably spent in indiarubber, the rubber itself being protected from mechanical injury by jute. Steel wires laid over the insulation render the cables difficult to handle, while they do not make them so strong that fracture is impossible. A striking instance of this came under the writer's notice a short time since. A pair of steel-armoured cables accidentally got on the tram-lines when a journey of coal-trams were passing. The cables were parted as by a knife.

It will thus be seen that electric transmission is now making steady progress, and is gradually pushing out both steam, compressed air, and rope driving, its rivals, and will probably continue to do so. No data have yet been published giving the actual cost of pumping, hauling, or coal-cutting by electricity. There should be plenty of materials now for comparing the cost of the electric pump with that of the steam, rope, and hydraulic pump. Moore's hydraulic pump, in which the ram consists of a long column of water, appears to be the most formidable rival the electric pump has to contend with at present. One of the principal difficulties that electrical haulage has had to contend with is the unequal strains brought to bear on the motor owing to the uneven nature of the roads over which the journeys of loaded coal-trams have to be hauled, and the increased tendency to sparking produced thereby. The most advanced proposal that has been made is that by Mr. Llewellyn Atkinson in a paper read before the South Wales Institute of Engineers a few months since. Mr. Atkinson suggests that in laying out new collieries, in place of having several engines in different parts of the colliery, doing various work, there shall be one or two large engines and dynamos fixed in some central position, and cables led to the different positions where work is required to be done, electric motors taking the place of the steam-engines now employed. Mr. Atkinson claims that the economy effected in this way at the centre will more than compensate for the losses of distribution and conversion. In the writer's opinion there can be little doubt that something of this kind will be the ultimate outcome, not only of colliery undertakings, but of many others, though how long it will be before this result is attained it is difficult to say. Already there are slight movements towards such a result. Some collieries already have a generating station from which electric currents are distributed for lighting, pumping, and hauling. As the education of the miner progresses, and as competition among collieries renders economy more and more needful, the plant will be more and more centralised, and no physical agent can compete with electricity where that is the end to be attained.

The prospects among mines at present are not bright. Colliery owners hesitate to spend money, even when future economies are clearly visible. The development of coalfields in various parts of the world is not only depriving coalowners of their markets, but is introducing competitors in other markets where they previously had none. Strikes in this country have given these competitors one opening after another, which they have rarely failed to take advantage of. Those who are closely connected with mines believe that electricity will be the salvation of the mine-owner. The difficulty at present is to make the mine-owner believe it too.

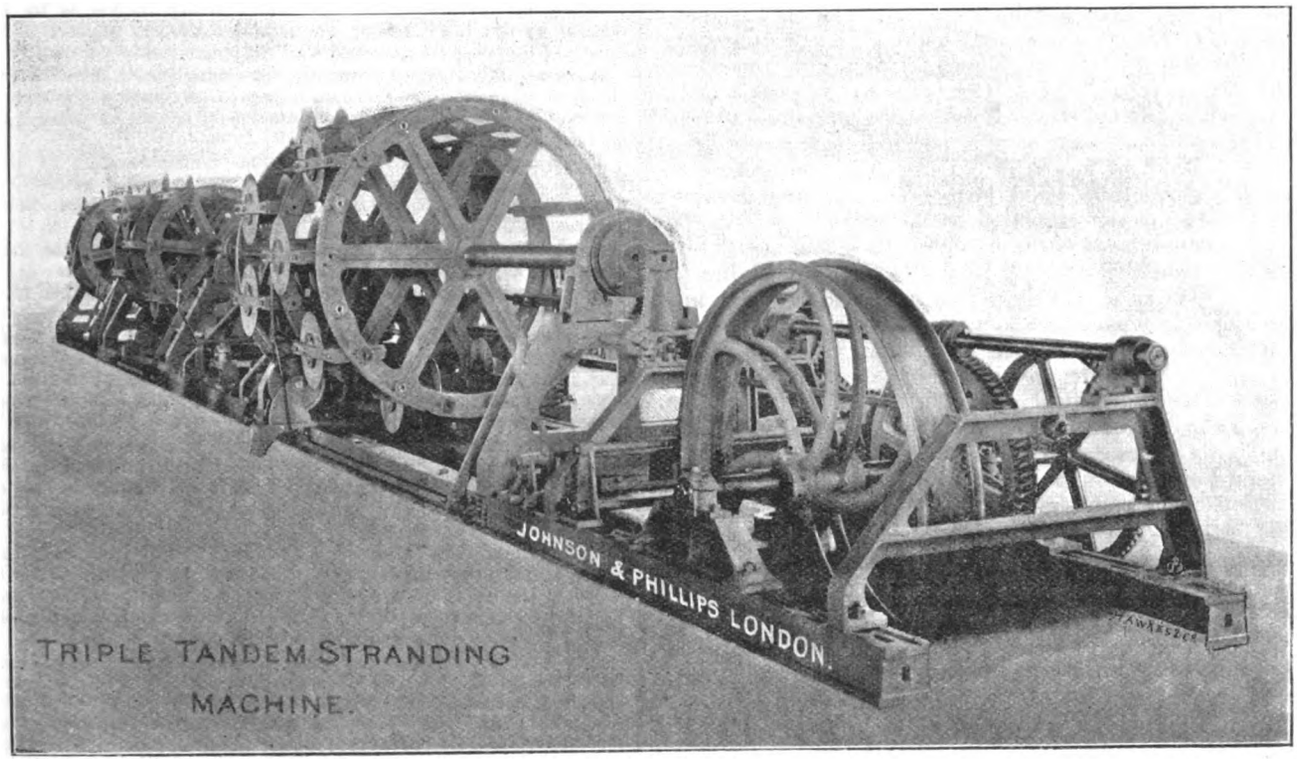
MESSRS. JOHNSON AND PHILLIPS'S TRIPLE-TANDEM WIRE-STRANDING MACHINE.

Owing to the great strides now being made in electric lighting and transmission, cable-making is becoming a most important industry, and we think, therefore, our illustration and description of a large wire-stranding machine which has just been completed by Messrs. Johnson and Phillips, of London and Charlton, will be of interest to many of our readers.

Digitized by Google

The machine in question, which has been built to the order of a large firm of wire manufacturers on the Continent, is what is termed a triple-tandem machine, and, as the name implies, consists really of three separate machines arranged "tandem." The first part is a six-wire machine, the second a 12-wire, and the third an 18-wire machine. Each part is arranged so that it may be run in the reverse direction to that of its neighbour, and at a different speed, and thus form a 37-wire cable in one operation. The centre wire being led through the centre hollow shaft, the first part of the machine lays six wires round it, forming a seven-wire cable; the second part lays 12 wires on this, forming a 19-wire cable; and the third part lays 18 wires over all, making up the 37 wires.

The machine will equally well make cables with a lesser number of single wires, or if a flexible cable is required, 37 strands made up of smaller wires could be used. The machine is also arranged that each part may be run in the same direction and at the same speed, and provision made for leading the wires from the first and second parts through the third, so that the whole of the 37 wires or any lesser number may be laid on a cable in one flake, as might be required in making a concentric cable. This also adapts the machine for making much larger cables.



For instance, if the 37-wire cable is passed through the machine again and covered with 24 wires a 61-wire cable is formed; this passed through again and covered with 30 wires forks a 91-wire cable, and this in turn can be passed through and covered with 36 wires, making up a cable of 127 wires. The bobbins each hold about 3cwt. of wire, and are suitable for all sizes up to No. 6 B.W.G.

All twist is kept out of the wires during the operation of cabling by means of the usual arrangement of cranks and eccentric rings. The ground space covered by the machine is 60ft. by 10ft., and it is erected on a continuous cast-iron girder bed running along its whole length. As will be seen on looking at the illustration, the draw drums are of large diameter, and they are driven by means of worm gearing, the speed being capable of considerable variation by means of change wheels to give the different lengths of "lay" for the wires.

The various parts of the machine are driven from a shaft running its whole length near the floor level. A novel feature in this machine is that the three sections are driven by chain gearing, and the builders believe this is the first example for a machine of this sort, and they claim that it is much quieter in working than the usual arrangement of spur-wheel gearing, the rattle of which causes so much annoyance. Another feature is that the central hollow shafts which carry the revolving part of the machine are provided at each end with heads which run on adjustable anti-friction rollers, and as the centre discs also run on similar rollers, the machine requires comparatively little power to drive it.

We understand that the machine is capable of making about three miles of cable per working day. Messrs. Johnson and Phillips have for some time been very busy in this department, and amongst other machines completed is one for the Postal Telegraphs for making seven-wire gutta-percha cables interlaid with yarns, and the whole covered with compounded tape, in one operation. We hope to give a description of this machine shortly.

ELECTRIC POWER PLANT AT THE CARTRIDGE FACTORY OF LUGANSK.

A correspondent sends us further information relating to this installation as follows:

The cartridge factory of Lugansk consists of 16 blocks of buildings, sufficiently distant from each other to reduce the gravity of accidents in case of explosion. These buildings contain five workshops, pump-chamber, central station, offices, powder and material stores, verification offices, stables, etc., and they cover a surface of nearly 30 hectares.

Under such circumstances, the distribution of power was rather a difficult matter with the usual system of mechanical transmission, the energy being produced by one engine only; on the other hand, the installation of an engine in everyone of the five centres requiring power would not have given an economical result, and, besides, it would have been necessary to place boilers within the buildings, which means an increase of the danger of explosion.

Electricity solved the question in a most satisfactory way, because it enabled a single central station to be placed in a separate building out of the radius of the others. The forge and the foundry being also placed at a distance from these buildings, and the shops being heated by steam, there is no fire whatever in the whole dangerous radius. The advantages of economy and facility resulting from the use of electricity are too well known to be again explained here, and we shall consequently only examine its applications in the factory of Lugansk.

Central Station.—There are in the central station five boilers, one of which will be a spare one, each of them having a heating surface of 2,480 square feet, producing

Digitized by Google

steam at eight atmospheres for the heating of the works and feeding. An engine of Felser's system, triple expansion, of an output of 400 h.p. and running at a speed of 82 revolutions per minute, is coupled direct to a 120-volt continuous-current dynamo (H. Pieper's system), and shunt wound. The dynamo is of the flywheel type. A triple-expansion 200-h.p. Felser engine, running at a speed of 150 revolutions per minute, is coupled direct to a shunt-wound 120-volt continuous-current dynamo of H. Pieper's system. These two dynamos are connected to a main switchboard, where all the working of connecting and distributing is done. The 400-h.p. is used to do the power work and the 200-h.p. engine does the lighting, but each of them can (the apparatus being disposed accordingly) do the work of the other one. The tension is maintained constant on the switchboard by two automatic magnetic-field regulators.

There are 25 separate circuits from the switchboard for the 25 motors and nine circuits for the lighting.

Motors.—The big empty-cartridge and ball shop, under one roof, contains: two 40-h.p. motors, one 25-h.p. motor, three 16-h.p. motors, and three 6-h.p. motors, each driving separate shaftings for the chasing machines and for the drilling machines by means of belts; also two 3½-h.p. motors driving automatic lifts by pinion gear; one 3½-h.p. motor driving direct a Schiele ventilator and blast engine of the lead-melting furnaces; and a motor of ⅛ h.p., coupled direct to a fan which works the blow-pipes annealing the ends of the empty cartridges. A 12-h.p. motor is placed in the shop where the bullets are fixed, and where the automatic weighing of the cartridges is effected; this motor drives a countershaft by means of a belt. The shop where the machines are repaired and the tools manufactured is worked by two 10-h.p. motors placed on the ground floor and two 6-h.p. motors placed on the first floor; these four motors drive separate countershafts. A ⅙-h.p. motor is coupled direct to a forge ventilator, and there is a 6-h.p. motor in the forge driving a drop hammer and a ventilator. A 3½-h.p. motor, coupled direct to a Schiele ventilator, is placed in the foundry. The waterworks, situated at a distance of 550 metres from the central station, is worked by two 16-h.p. motors and two 8-h.p. motors, driving four Worthington pumps of a respective output of 454 and 227 gallons of water per minute, at an elevation of 72ft. with 23ft. suction. The pumps are belt driven.

Lighting.—The works are lighted up with 62 C. I. E. 10-ampere arc lamps and 1,000 16-c.p. incandescent lamps. In the dangerous buildings the cables, although insulated with okonite, are encased in tubes. The lamps are placed in protecting globes; the fuses and switches are placed outside the houses to avoid all danger of explosion. During the night the yards and the shops are lighted up with 100 incandescent lamps, fed by a battery of accumulators of 640 ampere-hours. This lighting is intended for the night watchmen.

CONTRACTS FOR ELECTRICAL SUPPLIES.

CONTRACTS OPEN.

Posen.—Tenders are invited by the State Railway Authorities for the supply of 90 000 carbon pencils Conditions for 50pfg. from Die Königl Eisenbahn-Direktion, Posen.

Ploesti —The Municipality of Ploesti invites tenders by January 15 for the lighting by electricity of the 46 principal streets in the centre of the town Conditions from La Mairie de Ploesti Roumania.

Brussels.—The Ministère de la Guerre invites tenders by January 15 for (1) a heating installation, (2) electric lighting in the new military school to be constructed in the Avenue de la Renaissance, Brussels.

Aussig.—The communal authorities propose to have built a seven-mile single line tramway. The choice of system is left open. Contractors are invited to place themselves in communication with the Stadtrath, Aussig a.-d.-Elbe, Prussia. Tenders are to be in by January 31.

Dublin.—Messrs Arnott and Co., Limited, Dublin, invite tenders from competent firms for electric light and power installation to their new premises, Henry-street and Princes-street, Dublin. A copy of specification can be obtained from Mr. George P. Beater, M R.I.A.I., architect, 17, Lower Sackville-street, Dublin, on payment of £5. 5s., which will be returned on receipt of bona fide tender, which must be delivered at architect's office on or before January 8, 1896, endorsed "Electric Installation, Arnott and Co., Limited.

St. Pancras (London).—The Vestry invite tenders for the wiring and other work in connection with the electric lighting of the Vestry Hall and offices in Pancras-road. Specification and conditions of contract can be obtained at the Electricity Department Offices, 57 Pratt-street, N.W., on payment of £1, which will be returned on receipt of a bona fide tender; and a plan of the general positions of the lights can be inspected at the office of the borough engineer at the Vestry Hall, Pancras-road. Tenders to be sent to Mr. Albert E Pycraft, chief clerk Electricity and Public Lighting Department, 57, Pratt-street, N.W., endorsed "Tender for Wiring Vestry Hall and Offices," by 12 noon on the 16th inst

RESULTS OF TENDERS.

Coventry —The tender (£140) of the Electrical Engineering Company Limited, for electric lighting installation at the free library has been recommended for adoption.

BUSINESS NOTES.

Bristol Tramways Company.—The receipts of this Company for last week showed an increase of £154

City of London Electric Lighting Company, Limited.—Warrants for interest have been posted on this Company's 5 per cent. debenture stock.

Islington (London).—The electric lighting station is to be opened by the Lord Mayor, accompanied by the sheriffs. The date will probably be February 27.

Hornsey (Middlesex).—The District Council have decided that the application of an engineer in reference to lighting the streets and buildings in the district with electricity cannot at present be entertained.

Liverpool Overhead Railway.—The traffic receipts of this railway for the week ended December 29 amounted to £941, as compared with £837 in the corresponding week of 1894 being an increase of £104.

Bradford.—In view of the extension of the Corporation electricity works, which will shortly become necessary, the members of the Electricity Sub-Committee are making visits to other electricity generating works

Peterborough.—The borough engineer reported to the Town Council that he received a communication from Dr. Fleming stating that the current for arc lamps must be supplied from a separate circuit, and an estimate for street-lighting on this system is being prepared.

Johannesburg (Transvaal).—A Reuter's telegram in the *Times* states that the conditions of the Government contract for the establishment of electric lighting in the town forbid the use of English-made plant, and provide that only that made on the Continent is to be adopted.

Rotherham.—The Electric Light and Tramways Committee have decided to recommend that the town clerk be instructed to lodge a petition in opposition to the Sheffield District and Rotherham Tramways Bill. It was also recommended that application be made for a provisional order for electric lighting

City and South London Railway.—The returns for the week ended December 29 were £890, compared with £858 for the corresponding period of 1894, being an increase of £32. The total receipts for the half-year 1895 were £23,443, compared with £23,305 for the corresponding period of 1894, being an increase of £138.

Calendar for 1896.—The Chloride Electrical Storage Syndicate, Limited, have sent us a very attractive calendar in a neat frame. The dates are given clearly Some half dozen different types of accumulators manufactured by this firm are illustrated on the calendar. We note particularly the cell designed for traction purposes.

Western and Brazilian Telegraph Company, Limited.—The directors have received telegraphic advice to the effect that the necessary authorisation for the purchase of the Company's line had been continued by the Brazilian Chamber of Deputies and the Senate, and was included in the budget for the ensuing year. The receipts of the Company for the past week were £2,329

Trade Review.—We have received Messrs Bolling and Lowe's "Trade Review" for the year. "Electricity," this circular remarks, "is coming more and more to the fore as an actual factor in our daily life both for lighting purposes and motive power. There is good reason to believe that those experts are right who say, to use a popular phrase, that it is only in its infancy"

Newmarket.—After a week's consideration, the Urban District Council have resolved to object to the provisional order of the Newmarket Electric Light Company on the ground that as a drainage scheme was shortly to be considered for the enlarged area of the urban district, the steam machinery necessary for that might also be utilised by the Council for the supply of electric light to the district

Blotting Pad.—We have received from the Electrical Power Storage Company, Limited, a most useful blotting pad almanac and diary for 1896. The information contained in the beginning of the diary is of great service to all electrical engineers, and the

Digitized by Google

indexed diary forms a pleasing addition to this blotting pad, which has now become an established adjunct to the office furniture of an electrical engineer.

Salt Chemicals Syndicate, Limited.—This Company has been registered with a capital of £5,000 in £1 shares. Its objects are to acquire any patents, inventions, etc., relating to improved methods of producing caustic soda by electrolysis, or other kindred methods, and to develop and work the same. The first directors are to be elected by the signatories, and no qualification or remuneration is specified.

Aberdeen.—It has been reported at a meeting of the Gas and Electric Lighting Committee that the Secretary of State for Scotland had sanctioned further borrowing powers in respect of the electric lighting undertaking in the city. The committee have resolved to fit up shafting in the Corporation gas-stove depôt in Union-buildings, and to invite makers to send various kinds of electric motors for exhibition.

Chelmsford.—The committee of the Arc Works Relief Fund having met, Mr. H. C. Hawkins, who attended on behalf of Messrs. Crompton and Co., stated that practically all the men were at work again. It is probable that no further relief will be needed, but it was decided to hold over the £100 subscribed by Messrs. Crompton and Co , and four other sums, and the meeting was adjourned for a fortnight.

Madeira Electric Lighting Company, Limited.—This Company has been registered by Mr. R J. Twyford, 44, Finsbury-pavement, E.C., with a capital of £20,000 in £1 shares Its object is to enter into a certain agreement with Messrs. Ullathorne and Hartley for the acquisition of a concession to supply the city of Funchal with electricity for light, power, or other purposes The directors are to be elected by the signatories

Houghton Main Colliery (Yorks).—The electric lighting plant which has just been installed for the management by Messrs Crompton and Co. consists of six large arc lamps, four of which are 15-ampere, 3,000 c p. two 10-ampere, 2 000 c p , and 200 incandescents, with a dynamo giving an output of 240 amperes at 110 volts. The dynamo is driven by an engine of the ordinary horizontal type, giving about 40 h.p

J. C. Howell, Limited.—This Company was registered December 20 by Messrs Deacon and Co., 9 Great St Helens, E C., with a capital of £10,000 in £1 shares. The Company is to acquire all the property of the firm of J. C. Howell, and intends to carry on business as producers of and suppliers of electricity for the purposes of light, heat, power, etc. Mr. John C. Howell is to be sole managing director, his remuneration as such being £800 per annum.

Lockwood's Builders' Price-Book.—We have received from Messrs. Crosby Lockwood and Son, 7, Stationers' Hall court E.C., a copy of this book for 1896. About 30 pages are devoted to electric lighting prices, and the general conditions of supply of the City of London Electric Lighting Company are given as illustrating what the architect and builder have to provide for. In addition to this, the Phœnix Office Rules are added in full in an appendix.

Seamless Copper Steam-Pipes.—We are informed that the Marine Department of the Board of Trade have completed an exhaustive series of tests upon electrolytically formed seamless copper steam-pipes made by Elmore's Patent Copper Depositing Company, Limited, Leeds, and as a result the Board's inspectors have been instructed to pass this company's steam-pipes for use in passenger and other steamships built under Board of Trade survey.

Scotland and Electricity.—It has been noted that, while in England parliamentary powers are to be sought during 1896 by quite a number of municipalities and companies for the construction of electric tramways, from Scotland no such applications are announced. A similar large number of notices of applications for parliamentary powers for the supply of electric lighting have been lodged by English towns, while not a single application has been made from any town in Scotland.

Fareham.—The poll of the parish on the question of purchasing the undertaking of the Fareham Electric Lighting Company or the paying of the damages (£3,800) awarded in the recent lawsuit for nonfulfilment of contract has taken place. Contrary to expectation, the poll was not a heavy one, more than one-half of the electors not voting. The result was: for the purchase of the works, 431; payment of damages, 235—majority, 196 There were 16 spoilt or unmarked papers.

Dublin.—The burgesses' meeting to consider the Corporation Improvement Bill is fixed for February 5. At this meeting the burgesses will also be asked to pronounce upon the schemes embodied in the Rathmines, Dundrum and Blackrock District Tramways Company's Bill; the Dublin United Tramways Company's Bill; and the Dublin Southern District Tramways Company's Bill The executive of the Dublin Trades Council have issued a circular recommending that the scheme of the Southern District Company should be supported.

Wimbledon.—The Urban District Council have received a letter from the Local Government Board, stating, with reference to the Council's application to borrow £32,000 for the purposes of electric lighting, that in view of the early expiration of the electric lighting license of 1889, the Board would not be in a position to sanction the loan for any period longer than the unexpired term of that license. The chairman and clerk were appointed to wait upon the secretary of the Local Government Board. Wimbledon, with a population of 34,000, is at present lighted by means of paraffin lamps.

Kamm's Zerograph Syndicate, Limited.—This Company has been registered by Messrs. Osborn and Osborn, Exchange-chambers, Copthall avenue, E.C., with a capital of £12,000 in £10 shares. Its object is to enter into an agreement with L Kamm, and to carry on business as manufacturers of and dealers in telegraphic apparatus, or any other apparatus to be used for the transmission of messages. The directors are S. Reuschel and L. Kamm. The qualification is £100. Remuneration, £100, divisible; and the registered office 133 and 135, Old-street, E.C.

Tunbridge Wells.—The Lighting Committee have resolved that the thanks of the committee be given to the electrical engineer for the manner in which he carried out the arrangements in connection with the recent electrical exhibition, and that he be given a gratuity of £10. 10s from the exhibition fund for his services. It was also resolved that gratuities be given to the subordinate staff. On the discussion of the report of the Lighting Committee in the Town Council complaint was made of the neglect to light the side streets at night, and Mr Boot, the electrical engineer, explained that new machinery would soon be ready at the central works to meet extensions and the promised full 24 hours' pressure.

Elmore's Wire Manufacturing Company, Limited.—At the annual meeting of this Company, held in Leeds, the chairman (Mr. J. J. Atkinson) explained a financial arrangement whereby the Company would start the new year unencumbered by any old losses. He said the Company's sales had steadily improved since the beginning of 1895, when the sales of copper sheets were only a few tons monthly. Now further progress was only stopped by shortness of capital. In a short time a scheme would be propounded for largely increasing the Company's resources to meet the demand for high-class and higher-priced products. It has been decided to issue £7,000 worth of 6 per cent. debentures, more than half of which have been already applied for.

Sheffield.—The condition of the tramways question is at present as follows: The statutory town's meeting has been held to approve the Corporation's Bills for the working of the tramways of the city. The present company—the Sheffield Tramways Company—are applying for a renewal of their lease, and a new company—the Sheffield and District Tramways Company—have given notice of their intention to apply for powers to acquire the present system and to make numerous new lines all over the city, the new system to be worked by electricity. The town's meeting approved the decision of the Council to promote their Bill, and also consented to opposition to the applications of the two companies. At an informal meeting which followed, the Council were requested to apply for a provisional order so that in case they obtain possession of the tramways they may proceed with extensions at once. The Rotherham Corporation have also decided to oppose the Sheffield and District Company's Bill.

Glasgow.—Satisfactory reports are to hand concerning the working of the electrical power distribution plant put down a few months ago at the ironfoundry of Messrs. R. Maclaren and Co. Here a gas engine of 180 h p , supplied from gas from a producer, drives a dynamo from which an electric current is distributed to motors in various parts of the works. These motors vary in power from 3 h.p. each to 25 h.p. each, and the coal consumption is stated to be about 1¼lb of anthracite coal per hour per actual horse-power delivered by the motors at the points required. Sheriff Guthrie has given judgment in an action by the National Telephone Company, Limited, against Hugh Wilkie, watchmaker, Glasgow, for recovery of a year's rent for an instrument supplied by them to Wilkie From the evidence it appeared that Wilkie was somewhat deaf, but the Sheriff found that it was an implied condition of the contract that the telephone was to be made suitable to his special case, and that this was not done, despite repeated complaints. He therefore gave judgment for the defendant with costs.

Edinburgh.—At a meeting of a sub committee of the Lord Provost's Committee of the Town Council, a letter of the manager of the National Telephone Company suggesting that the Corporation should lay down underground tubes for telephone wires at the expense of the company was considered, and the sub-committee resolved to recommend that the proposals made by the Telephone Company should not be entertained. The Electric Light Committee have resolved to recommend that the following streets should be lighted by electricity: (1) from the Literary Institute to Salisbury-place, eight lamps, at a cost of £144; (2) from Waterloo-place to Abbeyhill, 16 lamps, at a cost of £288; (3) from Lauriston to Tollcross, 14 lamps at a cost of £252; (4) Dalry-road from Haymarket to Ardmillan-terrace, 20 lamps, at a cost of £360; (5) Fountainbridge from Freer-street to Viewforth, eight lamps, at a cost of £144; (6) Greenside to Pilrig, 25 lamps, at a cost of £450; (7) Frederick-street to Comely Bank, 18 lamps, at a cost of £324; (8) Hanover-street to Canonmills, 20 lamps, at a cost of £360; (9) Cowgate from the Grassmarket to St. Mary-street, 14 lamps, at a cost of £306.

Direct Electro-Generator Syndicate, Limited.—This Company was registered December 20 by Ashurst, Morris, Crisp, and Co., 17, Throgmorton avenue, E.C., with a capital of £100,000, divided into 100 000 shares of £1 each Its object is to adopt and carry into effect (with such modifications, if any, as may be agreed upon) an agreement expressed to be made between Charles P. Shrewsbury, John Cooper, Frank L. Marshall, and John L. Dobell of the one part and the Company of the other part, the said agreement being referred to in Clause 3 of the Company's articles of association, and generally to carry on, in all or any of their respective branches the businesses of electricians, generators, and suppliers of electricity, mechanical engineers, and manufacturers of and dealers in all apparatus and things required for or capable

Digitized by Google

of being used in connection with the generation, distribution, supply, accumulation, and employment of electrical energy. The signatories are: A. J. Seton, 36, Buckingham-terrace, Edinburgh; H. Dobbin, 4, Balmuir-terrace, Putney; S Spill, 24, St. Ann's-villas, Royal-crescent, W.; J. Cooper, 8, Furnival's inn, E.C.; F. L. Marshall, 22, Streatham-hill, S.W.; J. Lindsay, 32, Lupus-street, Pimlico S.W.; E Hills, 11, Paulton street, Chelsea. The first directors—of whom there shall not be less than three nor more than 10—are Major A. D Seton, Charles P. Shrewsbury, of Glyn Neath, Glamorganshire, Harry Dobbin, John Cooper, and Frank L. Marshall. Qualification, £250, and their remuneration is to be fixed by the Company.

Colchester.—The Town Council in committee presented a report, in which they stated that they had adopted a special report presented by the Lighting Committee, which had been to the effect that an important communication having been received from the officer commanding the Royal Engineers in the Eastern District in reference to the lighting of certain military premises, the Lighting Committee, in view of the letter from the War Department, and that a reply was evidently urgently required, recommended that the provisional order be put into operation, and that they be directed to take the following-mentioned proceedings on behalf of the Council—viz: Arrange terms with Mr. Massey, or other technical expert, to prepare a scheme, with specification and plans, on which tenders could be invited from firms of electrical engineers of good standing. Enter into provisional agreements with owners of suitable land on which works might be erected, and obtain plans, specifications, and tenders for the requisite buildings. Prepare particulars for the Local Government Board, with a view to application being made for their sanction to the borrowing of the sum required, and make provisional arrangements with the War Department for the supply of electric light, and report to the Council when these matters have been attended to, and obtain further instructions. On the motion, however, for the confirmation of the report, an amendment was carried adjourning the matter for a fortnight for further information.

Lightning Express Railway Syndicate, Limited.—This Company was registered December 23 by Messrs. Lindo and Co., 2 and 3, West-street, Finsbury-circus. E C, with a capital of £100 000 in £1 shares, 25,000 of which are 10 per cent. cumulative preference. The object is to acquire all the inventions now the property of Mr. Fritz B. Behr, of 6, Old Jewry, E C., in connection with lightning express or high speed railways, and in connection with improvements in carriages and electric locomotives for such railways and the sole and exclusive license to use the inventions belonging to the Lartigue Railway Construction Company, Limited, for the purpose of building, equipping, and working lightning expresses or high-speed railways. With a view to the above object the Company will adopt and carry into effect an agreement to be made with Mr. Fritz B. Behr. and generally carry on business as constructors of railways and tramways of every description, and in particular of those of a single rail on the Lartigue system of construction, and also as mechanical and electrical engineers, shipowners, carriers, and the business of a telegraph, telephone, and electric light company. The signatories are: L Clow, 22, Austinfriars, E.C; C. G Lindo, 2 and 3, West-street, Finsbury-circus; S F, Foster, 48, Victoria-road, Kensington; B G. Lake, The Priory, Orpington Kent; F. B. Behr, 6, Old Jewry, E C.; A. J. Sanderson, 66, St. James's-street, Pall-mall; N. S Russell, 39, Coleman-street, E C.; and the first directors—of whom there shall not be less than three nor more than seven—are to be elected by the signatories. The qualification is £100, and the remuneration £1 000 per annum for the first two years, after which as the Company may decide.

Swansea.—The Town Council, after hearing the adverse arguments of a deputation headed by Dr. Griffiths, have decided at their statutory meeting, by a majority of 30 votes to 7, in favour of prosecuting in the next session of Parliament the triple scheme for electric lighting and tramways and a dust destructor. Mr. R. Martin, chairman of the committee, in moving the formal resolution empowering the Corporation to proceed with its Bill, said the tramlines of the town were at present in a sad state, but under this arrangement they would be renewed, and the company enabled to run their cars at a profit. By getting the tramways company as a customer for their "day load" the Council would be enabled to sell electrical power for lighting at, not 6d. per unit, as had been suggested, but at 3d., and still leave a profit. Even assuming that they had to burn coal to generate the power, the total cost, including sinking fund, would be only £5,879 a year. That being so, could anyone doubt their ability to dispose of electricity at 3d. per unit—a price which meant something like 1s. 6d. per 1,000 for gas; 275,000 units at that price would mean £7,503. 16s. 8d, leaving a profit of £1,695 a year to go towards reduction of the rates of the borough. Mr. Martin went at length into the arguments in favour of the scheme, and said the result would be that the street-lighting would be done for nothing, and surplus power could be disposed of at 3d per unit. They had not pinned their faith on the destructor. As a matter of fact, it was absolutely necessary that a new method of disposing of town refuse should be adopted. This was the best means of destroying the refuse, and whatever heat could be obtained from it should be applied to the benefit and relief of the ratepayers of Swansea. In spite of the large majority on the Council there is influential opposition to the scheme, and it has still to be passed by a town's meeting.

South Staffordshire Tramways.—As the result of negotiations conducted by the Streets Committee of the Walsall Town Council, the Electric Construction Company have agreed to continue to run the electric tramcars on the present terms until the end of January. In the meantime the Mayor of Walsall will use his good offices in endeavouring to effect a more permanent arrangement. So far as concerns the portion of the tramlines worked by steam, the company have received permission from the Board of Trade to continue to use steam traction until March 25. Mr. Henry Hatchett, the secretary of the company, has been interviewed, and in reply to a question whether the company would consider the advisability of adopting some other means of traction between now and the expiration of the certificate, he said that the directors had already had the matter under their consideration. Speaking on the question of the cable system, he said he did not think their traffic would warrant its adoption In the first place, the initial outlay was very costly, whilst to make it pay a five minutes' service of cars was necessary. Again, the laying down of the cable would necessitate a suspension of the tram traffic, and would, he thought, constitute a considerable annoyance to the shopkeepers and residents on the lines of route. On the other hand, the overhead electric system, such as was at present working successfully in Walsall and part of Wednesbury, would not interfere with the present tram traffic; indeed, he said that the steam trams could run up to the very day of the adoption of the overhead electric system. The alteration of the system, was, however, a matter which called for very careful consideration, for the company at present possessed no fewer than 36 engines. How seriously the suspension of the running would have affected the public may be judged from the fact that the company during the course of a year carry passengers to the number of ten or eleven times the entire population of the various districts traversed by the steam trams.

Newcastle-on-Tyne.—The British Thomson-Houston Company, Limited, of London, have made an offer to work the trams of Newcastle by electricity, and in order to bring the matter before the Corporation have sent a circular to the town clerk and to every member of the Council asking the Council to hesitate before finally committing itself to the cable system. The company offer to provide a generating station with car sheds and engineering and repairing shops on land provided by the Corporation, and to relay the whole of the lines proposed to be equipped for cable traction, the trolley wire to be carried overhead on steel posts in a manner similar to that employed at Dublin and Bristol, and the whole of the work to be carried out at a cost not exceeding £86,000. They state that they are prepared to take a lease from the Corporation for 7, 14, or 21 years upon the terms that they (the company) supply at their own cost the requisite rolling-stock, consisting of cars carrying 43 passengers, and also, if necessary, double deck trail cars for use at times of exceptional pressure. They further agree to work the lines as to fares, times, and workmen's cars in accordance with the proposals embodied in the report of the Town Improvement Committee, with the addition of the running of a Sunday service if necessary. By way of rental they offer to pay 7 per cent. on the total sum to be arrived at by adding the cost and interest of the reconstruction, half the cost of widening Byker Bridge, and the proportion of the old debt applicable to this portion of the tramways (less the value of the old materials) and 3 per cent. on the value of the land. A half-yearly account of profit and loss would be issued, and of the net profits therein shown, 15 per cent. to be payable to the Corporation. The circular states that this will probably result in an annual profit to the Corporation in relief of rates of something like £1,200 to start with, which would grow with the increase of the city and the prosperity of the undertaking without any risk to the Corporation. In conclusion, the company say the work of reconstruction could be carried out in from six to nine months, but during the period little interference need take place with the existing horse traffic working. Correspondence on the subject still continues in the local Press, the tone being decidedly adverse to the decision of the Town Council in favour of cable tramways. The Newcastle-upon-Tyne Electric Lighting Company have just ordered from the Brush Electrical Engineering Company a 300-kilowatt Mordey alternator, making the sixth machine in this station, and bringing the total capacity of the station up to 900 kilowatts.

Wycombe (Bucks).—The Electric Lighting Committee having reported in favour of the Town Council entering into a contract with Messrs. Pritchetts and Gold for the electric lighting of the town, it was unanimously resolved to empower the committee to arrange the details of the contract. A subsequent motion to obtain the advice of an expert was lost, and it was also decided to give six months' notice to the gas company to terminate the present lighting contract. According to the arrangement with Messrs. Pritchetts and Gold, who will take over the Council's provisional order, the price for public lighting is to be £3 per annum per 16-c.p. lamp, the hours of lighting and other conditions to be similar to those in the present contract with the gas company, and the contract is to be for a term of 10 years. Electricity is to be supplied to private customers by meter at the rate of 8d. per Board of Trade unit, and the Corporation is to undertake to take a supply at the above rate for all municipal buildings and offices requiring artificial light. The Corporation is to have the option of purchasing the whole undertaking at the expiry of seven years from the date of commencing public lighting on paying the company a sum equal to the amount spent on the undertaking as shown by the Board of Trade return and certified by their auditor plus a profit of 15 per cent. If this option is not exercised at the expiry of seven years the Corporation to have the further option of purchasing at the expiry of 14 years on similar terms, but with the addition of 10 per cent. profit instead of 15 per cent. One year's previous notice of intention to purchase to be given by the Corporation. The Corporation to agree that the machinery and undertaking generally shall be exempt from rating, and that no other

Digitized by Google

company or firm shall supply electricity during the continuance of the provisional order. Whilst the public authority of Wycombe has been considering the introduction of the electric light into the town, a private firm has been acting for itself, and an installation has been completed at Mr. Jonathan Plumridge's Desborough-road Sawmills by Mr. F. W. Dickinson, of St. Ann's Electrical Works, Leeds. The installation consists of six arc lamps of 2 000 c.p each and 12 incandescent lights for the workmen's benches, etc., of 20 c.p. each. The current is supplied by a dynamo driven by a vertical high-speed engine made especially for electric lighting by Messrs. Marshall and Sons, of Gainsborough. Mr. Hammond, who recently acted as consulting engineer to the Corporation, has delivered a lecture at the free library on electric lighting. As an example of the cost of the light Mr. Hammond referred to the installation at Leeds, where, notwithstanding the fact that gas was only 2s 2d. per 1,000ft., the electric light company made a profit of 1 per cent. on the first complete year's working. He also gave extracts from accounts of consumers at Leeds, from which it appeared that the bill of a draper with 22 lights for the year was only £9 7s ; another, with 116 lights paid £29 10s. 6d ; a butcher with 20 lights, £7. 19s. 6d. ; a jeweller, with 92 lights, £20; another jeweller, with 132 lights, £20. 19s. ; and so on. Mr. Hammond also alluded to the healthy character of the light and the fact that illness in the Post Office had decreased by 60 per cent. since it had been used, and referring to the question of competition with gas he said that either the Corporation or a company coming to High Wycombe should be able to supply electricity at a price which would fairly compete with gas at 3s 6d. or 4s.

Blackpool.—Mr. Hesketh's report on the question of charges for electricity and proposed extensions has just been issued In reference to the scale of charges Mr. Hesketh remarks : "Under the Blackpool Electric Lighting Order, 1890, we are entitled to charge 'for any amount up to 20 units, 13s. 4d. ; and for each unit over 20 units, 8d.' We are also entitled to demand security and undertakings to take a certain supply for a period of two years from commencement of supply. At present our charges are : for any quantity used for incandescent lighting or for arc lighting, where charged by meter, 6d. per Board of Trade unit. Subject to the accounts being paid within one month of being rendered, the following discounts are allowed : on quarterly accounts to £5, 5 per cent ; £5 to £10, 7½ per cent. ; £10 to £20, 10 per cent. ; £20 to £50, 15 per cent. ; £50 to £100, 20 per cent. ; over £100, 25 per cent. To this scale there are at present only two exceptions : (1) the public arc lighting is charged at a uniform rate of 4½d. per unit irrespective of demand ; and (2) the Winter Gardens, under the first scheme of charges, had supply to arc lamps at 4d per unit, less 10 per cent This rate has not since been changed. The result of this scale of charges is that those of our consumers who use most energy, however and whenever demanded, have the best terms—the reason for this being that the custom of the largest consumers was considered as most valuable to us. This is true to a certain extent, and has up to the present worked well—whether it is advisable now to change it or not is for the committee to decide. The following are those consumers who have hitherto had the advantage of the full 25 per cent discount : Empire Theatre, Prince of Wales Market, and Winter Gardens. Those who reach the 20 per cent. scale are : Clifton Hotel, Imperial Hydro Hotel, and Victoria Pier Company. Many reach 15, 10 and 7½ per cent., and all have the opportunity of having 5 per cent. It is my firm conviction that upon this scale of charges the works will pay. There is a point at which consumption is as cheap for a consumer to supply his own electrical energy as to buy it from us on this scale. Seeing that the greater the demand the lower the cost of production (everything else being equal) it follows that we can make cheaper than they can, because, in addition to their demand, we have the demand from other consumers ; and therefore I maintain that rather than allow any large consumers to put down their own plant, it would be to our advantage to offer them terms just equal to or just below those on which they could supply themselves. For this reason alone I would recommend that we do not increase the price of supply to the largest consumers beyond 4½d. per unit. As the controversy on charges seems to have ranged round the Winter Gardens Company, I may be allowed to give data as to their consumption during the past four quarters : total units, 77,914·4, cost £1,390. 0s. 8d. ; or, an average of 4·3d per unit. The fact that the Winter Gardens have a demand which is very irregular, is to a great extent counterbalanced by the fact that in the season they have an afternoon demand of some magnitude." Mr. Hesketh describes the extent and capacity of the present plant at Blackpool, and says that the Corporation have overspent their borrowing powers, which amount to £50,577, by £739. The sinking fund amounts to £2. 11s. 4d. per cent , which is equal to the "antiquation" of the whole plant in 25 years Owing to the rapid advances made in the type of plant, it is advisable to supplement this £2. 11s 4d. per cent. by a further fund. The sinking fund for repayment of loans in 25 years is £2. 11s 4d. per cent. ; for 20 years, £3. 10s. 9d. per cent. : and for 15 years, £5 3s. 8d. per cent. ; and to decrease the period of total redemption to 15 years means the increase of the sinking fund by £2. 12s. 4d. per cent. per annum. It follows that on this calculation the total depreciation amounts to £3,162, or just over 6 per cent. Against this the Corporation are compelled by the Local Government Board to put by £2. 11s. 4d. per cent , and in addition all renewals, repairs, etc., are met out of maintenance, and therefore the plant can always be considered as approximately kept up to the original standard of efficiency out of the working expenses It appears, therefore, that every reasonable contingency would be met if a further provision of 2½ or 3 per cent. on the total capital were placed to a reserve fund every year. From a return supplied, Mr. Hesketh shows that the profit for the past half-year ending September 30, 1895, is £300, which can be set off to reduce the loss of last year. The report adds that "the question as to new consumers requires consideration. Intending consumers will not send in their applications so long as they know they cannot be supplied, yet we have received applications for fully another 100 kilowatts supply, even excluding the additions to the Winter Gardens and to the public street-lighting. With these two last items we should, if extensions are gone on with, have to connect to the mains within the next 12 months fully 200 kilowatts more than at present. At least four months must elapse before we can have the first of any new plant running for supply, and therefore, if extensions are to be gone on with, some definite steps must be taken at once. We have hitherto used Lancashire boilers exclusively, and they have done their work well, with one exception, which is that on account of our load being a maximum for only about four hours of the day. If steam is to be raised in Lancashire boilers for these four hours it involves alternate strains of expansion and contraction, which eventually weaken and damage the boiler. A Lancashire boiler for safe constant working cannot be improved upon, but for rapid steam raising to take a maximum load it is not altogether adapted. Not only so, but for equal power it takes up more room than any other type of boiler, and it is my wish to put before the committee a scheme by which the extensions can be carried out under the same roof as the present plant, and so avoid not only the extra capital cost of new buildings, but the increased working cost which would naturally accrue from more extended premises with plant scattered over a wider space. I would, therefore, recommend the placing of two boilers of the marine type between the two existing batteries, which would give us a further capacity of 1,000 h p., and a slight margin for space. Not only so, but the marine type of boiler lends itself particularly to the use of induced or forced draught. This is important, seeing that for three hours of the day our chimney capacity is also deficient, and that if we use Lancashire boilers we shall be obliged to build another chimney. With marine boilers and induced draught even now a new chimney will not be necessary." In reference to engines and dynamos, Mr. Hesketh remarks that "hitherto the custom has been to consider these separately, but the most recent practice is to build the dynamo round the flywheel of the engine. By such means we can get 500 h.p., or 300 kilowatts, into a very much smaller space than we otherwise could have done. But seeing that all the space is already taken up in our engine room, the following is the best recommendation I can make : The three small arc dynamos and engines are comparatively inefficient — that is to say, they can only give an efficiency of 40 per cent., whereas the larger engines can easily give 80 per cent. I would therefore recommend that these three small engines be replaced by two large engines of 500 h p. each. Into the same space as that now occupied by 180 h.p. we should get 1,000 h p. The cost of each of these small sets of plant complete was originally £831, or say, £850. Supposing that we can now get half-price for these engines and dynamos, we entail a loss of £1,275, against which is to be placed a saving in buildings and an economy in working the station. I feel sure that the cost of buildings alone to cover the new engines will far exceed this amount, and from the plan the new arrangement of plant gives a far more compact and workable station than we have at present. The alternative to this scheme is to build an extension to the present building, and place in it the new engines and dynamos, but I do not recommend this. In the specification for the boilers, I have provided against trouble from smoke ; in the engines, the arrangement of steam-pipes prevents the escape of moisture into the street ; and in the dynamos I propose to insert clauses as to immunity from trouble through noise. I have inserted a clause in the specification that the contractor for the dynamos must guarantee that in the quiet hours of the night, with the windows of the works open, the occupants of houses in the adjoining streets shall not be able to distinguish whether the engine is running or not. Provision for a further 25 street lamps has been made, together with a rearrangement of the circuits, so that no two adjacent lamps are on the same circuit. To complete the engines and dynamos alone will take four months, and unless orders are placed before January we shall be unable to meet next season's demand. Although in this scheme I have allowed for the addition of 1,000 h.p., the specification is so drawn that only half the scheme need be undertaken immediately if the committee so decide. In my opinion, however, the full scheme is necessary under the existing state of affairs."

PROVISIONAL PATENTS, 1895.

DECEMBER 16.

24049. **Improvements in electrical contacts.** Adrien Joseph Moulart and Artien de Galard, 8, rue des Princes, Brussels.

24055. **Improvements in the construction of electric cable joint-boxes, more especially for those of concentric type.** Robert Cornelius Quin, 18, Hamilton-road, Brighton.

24079. **Improvements in collectors for electric railways and tramways.** William Edward Parry, 70, Chancery-lane, London. (John Parry, United States.)

24092. **Contact apparatus for night and sound signalling and telegraphing.** Cornelis Vreede, 323, High Holborn, London. (Complete specification.)

Digitized by Google

24098 **Improvements in continuous-current generator-dynamos or motor-dynamos.** Albert De Puydt and Maximilien Poncin, 60, Queen Victoria-street, London. (Complete specification.)

DECEMBER 17.

24136. **An automatic check or governor for controlling the trolley (trolley-wire system of electric traction).** Henry Brecknell and Thomas Bradley Holliday, 64, Lawrence-hill, Bristol.

24151. **An automatic electric fog signal and general danger signal indicator and communicator.** William Edward Penfold, 50, Culmore-road, Peckham, London.

24165. **Process for hardening the active material on the positive plates of secondary voltaic batteries.** Ludwig Epstein, 28, Southampton-buildings, Chancery-lane, London.

24166. **Improvements in incandescent electric lamps.** The Edison and Swan United Electric Light Company, Limited, and Edward Alfred Gimingham, 28, Southampton-buildings, Chancery-lane, London. (Complete specification.)

24172. **Improvements in or connected with galvanic batteries.** Armand C. Iwanoski, 6, Lord-street, Liverpool.

DECEMBER 18.

24222. **Improvements in multiplex telephony.** Daniel Sinclair, 62, St. Vincent-street, Glasgow.

24264. **Resistance switch apparatus for starting electromotors.** Siemens Bros. and Co., Limited, 28, Southampton-buildings, Chancery-lane, London. (Siemens and Halske, Germany.)

24296. **Improvements in or connected with rotary electric transformers.** Alexander Bewicke Blackburn and Wilfrid L. Spence, 47, Lincoln's-inn-fields, London.

24304. **Improvements in incandescent electric lamps.** Mark Bailey and John Warner, 21, Finsbury-pavement, London.

DECEMBER 19.

6565A. **Improvements connected with the electrolysis of chlorides and other salts, and the evaporation of solutions.** Harry Tee, 15, Water-street, Liverpool. (Date claimed under Patents Rule 19, March 30, 1895.)

24354. **Improvements in electrical switches.** Charles Mark Dorman, Reginald Arthur Smith, and Herbert George Baggs, Ordsal Electrical Works, Salford, Manchester. (Complete specification.)

24375. **Improvements in electric arc lamps.** Ignace Hippolyte Hegner, 6, Lord-street, Liverpool. (Complete specification.)

24393. **Improvements in reflecting incandescent lamps.** Audley Charles Miles and Bernhard Fietz de Morgenstern, 151, Strand, London.

24394. **Improvements in and relating to galvanic batteries.** Audley Charles Miles and Bernhard Fietz de Morgenstern, 151, Strand, London.

24398. **Improvements in means for controlling or directing electric currents.** Charles Pollak, 47, Lincoln's-inn-fields, London.

DECEMBER 20.

24437. **Improvements in electrical and other gas lighters and extinguishers.** The Anglo-Swedish Trading Association, Limited, and Oscar Ehrenfried Woollert, 64, Aldersgate-street, London. (Complete specification.)

24443. **Improvements in portable electric lamps for use in mines and other places.** Sydney Ferris Walker, Cardiff Electrical Works, Severn-road, Cardiff.

24444. **Improvements in holders for electric glow lamps and analogous electrical contact devices.** Emil Hungerbühler and the Electrical Company, Limited, 433, Strand, London.

24447. **Improvements in the separation from their cathodes of electrically precipitated gold and silver from cyanide solutions.** Charles Maria Pielsticker, 60, Queen Victoria-street, London.

24465. **An improved electric contact button.** Audley Charles Miles and Bernhard Fietz de Morgenstern, 151, Strand, London.

24466. **Improvements in electric indicators.** Audley Charles Miles and Bernhard Fietz de Morgenstern, 151, Strand, London.

24467. **Improvements in incandescent lamps.** Audley Charles Miles and Bernhard Fietz de Morgenstern, 151, Strand, London.

24471. **Improvements in devices for protecting electric circuits and apparatus from injury by excessive electrical potential due to lightning or other cause.** Valere Alfred Fynn and Easton, Anderson, and Goolden, Limited, 47, Lincoln's-inn-fields, London.

24472. **Improvements in dynamo-electric machines.** Valere Alfred Fynn and Easton, Anderson, and Goolden, Limited, 47, Lincoln's-inn fields, London.

24473. **Improvements in or connected with incandescence lamps and filaments therefor.** Charles Henry Stearn, 47, Lincoln's-inn fields, London. (Charles Frederick Topham, Switzerland.)

DECEMBER 21.

24503. **Improved electric insulators.** Robert Atherton, 8, Quality-court, Chancery-lane, London.

24514 **Improvements in means or devices for holding electric incandescent or glow lamps.** Robert Hacking and John Bennett, 78, Fleet-street, London. (Complete specification.)

24516 **Improvements in secondary voltaic batteries.** Ludwig Epstein, 28, Southampton-buildings, Chancery-lane, London. (Complete specification.)

24539. **Improvements in electric regulators.** Audley Charles Miles and Bernard Fietz de Morgenstern, 151, Strand, London.

24556. **Improvements in suspension devices for electric and other lamps.** Etienne Jullien, 45, Southampton-buildings, Chancery-lane, London.

NOTES.

Electricity in Gold-Mining.—At Piggs Peak Mine, in South Africa, the 30-stamp mill recently erected will be driven by power electrically transmitted from the waterfalls about six miles distant.

Telephone Difficulties.—All the telephones in Naples were rendered useless for a time last week owing to one of the wires of the electric lighting at Chiaia coming into contact with the telephone wires.

Telephone and Telegraph.—The head of the Telegraph Department at Valencia (Spain) has decided that several telephone lines that have been erected and worked without the consent of the authorities being obtained should be summarily cut. *El Telegrafista Español* would be greatly pleased if other local heads of departments were to look up similar cases of unauthorised telephones in their various districts and treat them in the like manner.

Electrotherapeutic.—A paragraph has been going round the Continental electrical papers on a method of stimulating the nerves of the stomach devised by Drs. Einhorn and Ewald. Currents of from 15 to 25 milliamperes are used, and the patient, having previously drank a quantity of water, has passed into the stomach a perforated vulcanite capsule containing one of the electrodes, the connection being maintained by a wire insulated by an indiarubber tube. Dyspepsia is unpleasant, but one would imagine this remedy was as bad as the disease.

Utilising the Scorcher.—Various devices have been invented for enabling the cyclist to train or take his exercise indoors during bad weather. It has occurred to a French electrician that he might at the same time be doing some useful work. Accordingly, an apparatus is described in *L'Etincelle Electrique* by which the driving wheel of a safety bicycle of the usual type is raised from the floor and by means of a strap and speed gearing drives a small dynamo which is used to charge accumulators. The arrangement is designed to give a current of seven amperes at 20 volts.

The National Electrical Exposition in America. An electrical exposition under the auspices of the National Electric Light Association, and approved by the American Street Railway Association, is being planned to be held next May. The convention will be held in the New York Industrial Building, Forty-third-street and Lexington Axe, and the business will be conducted by the National Electric Exposition Company, which has been formed for the purpose. The Industrial Building was constructed expressly for exposition purposes; it has seven storeys, with roof garden, a lighting plant of 5,000 incandescent lamps, and a spare steam plant of 300 h.p. The office of the Exposition Company is at 126, Liberty-street, New York. It is contemplated to make this the greatest electrical exposition ever held.

Marine Engineering Design.—The council of the Institution of Junior Engineers, 47, Fentiman-road, London, S.W., announce that arrangements have been completed for a course of six lectures on this subject, to be given by a gentleman of long experience on the North-East Coast, and now occupying the first position in the designing department of one of the leading London marine engineering works. The lectures will be specially prepared to be of practical benefit to those attending them, the great importance of economical, as well as efficient, design being kept in view throughout; and as there will be many questions considered affecting steam-engine design generally, they will be of interest and value to engineers not exclusively engaged in marine engine work. The following are the dates of delivery: February 3 and 17; March 2, 16, and 30; and April 13, at 7.30, at the Westminster Palace Hotel. The fee for the course is 12s.

Thunderstorms.—M. Albert Nodon has communicated to *L'Electricien* the results of certain researches made in connection with the department of physics at the Sorbonne. A Mascart electrometer was connected by a thin insulated copper wire to insulated metallic discs placed at some distance from each other in the open air, and it was found that the maximum potential obtained was the same during any one storm, and was independent of the distance of the disc from the spot where the lightning discharge took place. It is concluded from this that a thundercloud acts as an efficiently good conductor to be considered as presenting an equipotential surface, and that the electrical equilibrium, so far as the cloud is concerned, is rapidly re-established after each flash of lightning. It was possible to tell when a flash was about to occur by noting the rate at which the electrometer readings progressed towards the maximum.

A Suspended Beam Electric Tramway.—The *Electrical Review* of New York has some illustrations of an interesting suspended beam electric tramway, put up by the Brown Hoisting and Conveying Machine Company, of Cleveland, at the works of the National Carbon Company at Cleveland. The system consists of an electric travelling hoist running on a suspended beam track. The hoist is suspended from four axles, with track wheels, which run upon a track made of 10in. channels, with the flanges inwards. These channels are spaced about a foot apart. The motor is a 10-h.p. Brush mining type, designed for 220 volts. The current is communicated to the machine by means of two trolley wires, one on either side of the channel-iron track. The hoist has been erected for the purpose of transferring bulky furnace tops, weighing from 3½ to 4 tons each, from one furnace to another.

Bare Conductors.—The following exemplifies the dangers attached to the practice of fixing bare electric light conductors on the same post as telephone or other circuits, particularly where the former carry high-tension currents. At Grunberg, in Silesia, the other day, a linesman named Weinhold mounted one of the high poles to attend to some repairs to the telephone wires under the impression that the electric light circuit was switched off. Standing on one of the insulated hooks of the telephone line, he was about to secure himself by passing a rope round his body and the pole when his head touched one of the bare electric light mains above, and he received the full force of the 10,000-volt current. The result was that he immediately fell from the top of the pole to the ground and broke his spine. There were considerable burns on the neck and feet clearly showing where the current had entered and left the body, and the unfortunate man died almost immediately afterwards.

A French View of the Voltage Question.—M. Mondon, of the Compagnie Electrique de la Loire, has communicated a note to the Chambre Syndicale des Industries Electriques in reference to the regulation of September 15, 1893, which authorises the use of bare conductors when the difference of potential does not exceed 120 volts for alternating and 400 volts for continuous currents. "It results from this regulation," he remarks, "that insulated wires must be used when the three-wire system is adopted with alternating currents, since there is a difference of potential of 240 volts between the two outside wires. But a pressure of 240 volts alternating is much less dangerous than one of 400 volts continuous, and it would therefore be reasonable to authorise the use of bare conductors with alternating currents provided that the pressure did not exceed 240 or 250 volts. Assuming that

Digitized by Google

the danger is proportional not to the effective but to the maximum pressure only $150 \times 52 = 355$ volts should have been allowed in place of 400 for a continuous current."

France.—The principle of electric traction may now be regarded as fairly established in France, at any rate so far as concerns the provinces. The system has been started already at Havre, Dijon, Bordeaux, Lyons, Cimiez, Toulon, Rouen, and other towns, and a very large number, indeed, of lines are either projected or in course of construction, so that *L'Energie Electrique* remarks that on all sides endeavours are being made to substitute electric for horse traction. In almost every case the overhead system is adopted, but one line, from Nice to Cimiez, is run with accumulators. The pattern of these has, however, been more than once changed. There has also been some advance in the use of gas-engines in place of steam for generating purposes, but with the exception of Cambrai the gas companies have done little to encourage these. The use of petroleum-engines as auxiliaries to water power on occasions of short supply may be also noted, as this removes one of the difficulties in the way of the utilisation of much energy which now runs to waste.

The Light from a Crookes Tube.—There has been telegraphed from Vienna the summary of an article in the *Presse* in reference to a discovery made accidentally by Prof. Röntgen, of Würzburg, while experimenting with Crookes vacuum tubes. The discovery, which is stated to have been accepted by Prof. R. Boltzmann, of Vienna, is in effect that a photographic plate is affected by radiations from a Crookes tube, which are entirely beyond the range of the visual or what has hitherto been considered the photographic spectrum. While metallic conductors are opaque to the new radiations, wood and many organic substances are transparent to them, so that by their use it has been possible to obtain a photographic image of a metal object enclosed in a wooden case. It is suggested in Vienna that these radiations are really an extension of the ultra-violet spectrum, but there is, of course, the possibility that the effect is due to undulations of a comparatively long period. If the discovery is substantiated, further details will be awaited with interest. The repetition of the experiment has not yet been successful in Vienna, where the Crookes tubes at the disposal of the experimenters were not sufficiently large.

Pressure and Conductivity.—An article by Gustav Tammann in *Zeit. Physikal. Chem.* is summarised in the *Journal* of the Chemical Society: The influence of pressure on conductivity may be divided into three factors: (1) volume alteration; (2) alteration of viscosity and ion friction; (3) alteration of the degree of dissociation. The effect of pressure on viscosity has been determined by Cohen for sodium chloride solutions: the viscosity of solutions of small internal pressure diminishes with increase of pressure, the reverse obtaining with solutions of high internal pressure. The effect on the dissociation constant is given in a table of percentage alteration due to pressure of 500 atmospheres for solutions of varying concentration and dissociation. The total effect is then considered and typical curves are given. At infinite dilution, factors 1 and 2 alone are weighty, and these cause an increase of about 4·5 per cent. (for 500 atmos.). If the concentration increases, there are three types of curves: (I.) where the electrolyte is feebly dissociated, the curve rises to a maximum and slowly falls; (II.) where the dissociation is great and factor 3 of small account, the curve is at first almost parallel to the axis of concentration, then slowly sinks owing to the effect of the viscosity, and finally cuts the axis; (III.) for intermediate dissociation, the rise is not as rapid as in (I.), and a well marked maximum occurs. The curve is also given in the case of sulphuric acid, which is shortly considered; a maximum occurs here at concentration 0·5 per cent. and a minimum at 85 per cent.

The Electrical Trap Again.—The *Indian and Eastern Engineer* is responsible for the following: "All dwellers in India whose tempers have been at times ruffled by the persistent and extremely inharmonious efforts of crows to make their presence known will be glad to hear, according to a contemporary, that an electrician has directed his attention to their extermination. In fact, the *corvus impudicus* is to be electrocutioned; but the act will be suicidal, and this is how he proposes to make him carry out that act: Between two metallic horizontal bars, which are the positive poles of a powerful battery, is hung a wire basket, which is the negative pole of the battery. In this wire basket is placed moistened food, which can only be got at by a bird perching on either of the aforesaid horizontal bars. The birds cannot see each other from these bars. Below these perches is fixed a large box, with slanting pivoted tops, which is got at from the room without any fear of being seen by the birds outside. As soon as a crow perches on one of these bars and begins to draw the moistened bait out from between the meshes of the cage, he establishes the circuit, is killed, and drops on to the slanting lid of the box, which revolves and deposits him for future cremation in the box, and adjusting itself hides the criminal from further view."

Niagara Falls.—The New York *Engineering Magazine* for December contains an article by the late Franklin Leonard Pope on the "Distribution of the Electric Power Obtained from Niagara Falls." In the article, which was left incomplete by the author's sudden death and is finished by his brother, Mr. R. W. Pope, it is remarked that the results which have been already attained culminating on the transmission of electric energy to the amount of some thousands of horse-power to the works of the Pittsburgh Reduction Company, make it certain that the vicinity of the Falls will in time become one of the greatest manufacturing districts of the United States. But the question of the transmission of power to a distance so as to compete with steam power produced on the spot still awaits its solution. In spite of the favourable opinions expressed by many electrical engineers, it is noted as significant that, so far as can be learned, no work has actually been commenced upon the transmission line to Buffalo. It is urged that it is not always safe to base important plans upon possible economies. In the case of steam plants, the economy to be derived from grouping plants so as to work from a central power station operated at high efficiency has to give way to the local convenience of separate plants. It might result that the flexibility of electrical distribution would lead to the substitution of the motor for the steam-engine where the question of heating was of little importance. It is concluded that all manufacturing enterprises in the United States, unless of a strictly local character, will be henceforth located only after a thoughtful consideration of the great advantages of Niagara.

Steam Ploughs.—A consular report of Mr. O. Döderlein, United States Consul at Leipsig, deals with the application of electric motors to steam ploughing in Germany. In the usual system of steam ploughing, in which the plough is pulled by a wire rope coiling on a drum, the friction of the rope is very great, so that the horse-power required at the engine is quite disproportionate to that which is available at the plough. Moreover, the rope wears rapidly and is costly to replace. These considerations proved fatal to the "all round" rope system with one engine, leaving at present only the double-engine

Digitized by Google

system, with its double expense for capital and attendance, to maintain a precarious existence down to the present time. An obvious improvement would be to make the plough drag itself along a fixed rope, but short of taking a more or less heavy steam-engine across the field there was until the advent of the electromotor no convenient method of supplying energy to the plough. The suitability of a dynamo and motor for this purpose is obvious at first sight, and it is probable that had not the condition of agriculture in this country been such as to offer no encouragement to projects involving the outlay of considerable capital, a system on these lines would have been worked out here. It has, however, now been done in Germany with some success. The plough, carrying an electromotor, pays out and picks up a separate conductor cable as it crosses the field, and the cost of working is stated to be about one-half that of oxen. No details are given in comparison with horses. As, however, in the experiments given a 10-h.p. engine was required to work a two-share plough, there is evidently still room for improvement, since two single-furrow ploughs would require only four actual horses to work them, or, since the soil is stated to be heavy clay, six horses at the outside.

Piano-Playing by Electricity.—In the current number of the *Scientific American* is an article on an electric apparatus which can be attached to any piano, enabling it to be played without the intermediation of any performer. The apparatus is fixed immediately under the keyboard of the piano, and is so constructed that it can be fed with perforated music-sheets. Electric contacts are provided for each note, which contacts operate through the perforations in the music-sheet, so that each perforation closes an electric circuit. From the electric contact, wires run to a series of electromagnets placed below and corresponding to each key of the instrument. When the current passes, a magnet attracts its armature, and this occurs when one of the perforations closes the circuit. A long brass drum runs across the bottom of the apparatus and is kept in constant rotation by an electric motor. Extending from the end of the armature of each magnet is a metal friction shoe, the lower end of which forms the segment of a circle, and is arranged to be brought in contact with the brass drum. A piece of raw hide is cemented to the outside of the segment, and when the armature is depressed it brings the raw hide-covered face of the segment into contact with the rotating drum and the friction at once throws the arc forward. From the upper end of the metal shoe a short arm projects at right angles, and from this a vertical striker arm rises and presses against the inner end of the key, which is then set in motion just as if the outer ivory-covered end were depressed by the finger of a performer, and the note sounds. It is stated that this apparatus does not affect the capacity of the piano for being played by hand. It is also stated that the motor consumes from five to ten amperes at a pressure of four volts, ten amperes being required when several notes at once are sounded, as in a chord.

Utilisation of Mountain Streams.—Mr. Bunten, the proprietor of Rannoch (Perth) has recently put down an electrically-driven threshing machine at his home farm, and it was exhibited about a week ago to a large number of Perthshire agriculturists. The contents of three burns which come down the side of Schiehallion are discharged into a dam fully three-quarters of a mile from the mansion house. From the dam the water is conveyed fully 500 yards in 10in. iron pipes to the dynamo-house. In the dynamo-room there are two turbines and two dynamos. The turbines are 12½ h.p. each, and arrangements are made so that one turbine and one machine can run, or the two together if required. The current is led by two conductors from the dynamos to the mansion house, a distance of between 400 and 500 yards, and there are branches from the house to the stables and laundry, about 200 yards beyond. The premises are fitted with fully 300 lamps, of which from 150 to 160 are generally in use. As the capacity of the cable is sufficient to carry double the number of lights that were originally fitted up, Mr. Bunten (who is managing partner of the Anderston Foundry Company, Glasgow), after deciding on making an experiment as to the application of electricity as a motive power for machinery, resolved to extend the cable from the mansion house to the steading, a distance of 940 yards. The difficulty in the way of using water power for this purpose is that, according to modern agricultural practice, threshing is not an operation that goes on continuously through the winter, but is done in large parcels at a time, and consequently more power would be required than is likely in most cases to be available. There are, however, a quantity of minor operations about a farmstead which are fairly continuous during the winter season, when the streams are full, and which are quite suitable for such an application of water power as is described above.

"Are We Educating Too Many Electricians?"—Mr. Henry Floy, writing under this heading in the New York *Engineering Magazine* for January, says that to meet the growing evils of what he terms "electro-mania," there is urgently needed an educating of popular thought as to the possibilities of electricity and the business opportunities offered in electrical engineering. It had been stated that the time was rapidly approaching when every central-station lighting and power plant and every form of electrical business would have their consulting and installing engineer; but he thinks such a statement misleads the public, because the electrical manufacturing business is daily tending to the production of more simple apparatus which may be operated by those who are ignorant of electrical laws, and, as a consequence, there is less and less call for the highly-educated theoretical man in the more usual practical applications of electricity. Feeling sure of the over-production of electrical engineers, and in order to secure some facts as a verification of his convictions, he sent 260 personal letters to the present year's graduates in electrical, mechanical, and civil engineering. His idea was to procure statements which would show comparatively the number of positions secured by recent graduates in these three courses, to ascertain whether influence was necessary to secure positions and to determine the salaries paid in these positions. He sent 108 electrical letters and had received 48·1 per cent. replies. Of these, 78·8 had secured employment, and 65·3 had secured employment in the line of work for which they studied; and of the total, 36·4 had secured employment through the influence of relatives and friends. The average rate of pay per hour on the basis of 5½ working days per week was 21·8 cents. The conclusions he drew from these statistics were that, while a greater percentage of the graduates in electrical engineering secure employment as compared with the other graduates, yet the fewest, relatively, secure employment in the line of work for which they had studied—that is, in order to get employment, they had to take positions in which their electrical knowledge did not count. Assuming 5½ working days per week for each of the three professions, the electrical graduate received over 20 per cent. less per hour than the mechanical graduate (who received 27·4 cents), and 23 per cent. less than the civil graduate (who received 28·5 cents).

Thermo-Electricity.—Profs. J. Dewar and J. A. Fleming have determined the thermo-electromotive force

Digitized by Google

at temperatures as low as the boiling point of liquid air; the couples were in all cases prepared by the junction of the metal wire, "M," with a lead wire, and the observations were afterwards reduced to those of a couple of "M" with pure lead. Measurements were taken at about 30 temperatures between 100deg. and −200deg. (the temperature being determined by a platinum resistance thermometer, and recorded in "platinum degrees"), and very careful measurements were taken at fixed temperatures—that is, the boiling point of oxygen, melting point of solid carbonic anhydride, etc. The metals examined were platinum, gold, palladium, silver, copper, zinc, cadmium, magnesium, tin, iron, nickel, steel, manganese steel, maganin, German silver, platinoid, bismuth (A, B, and C), antimony, and aluminum, and also carbon. The lines (E.M.F. against T) are in all cases curved, with frequently a maximum, but none are exact parabolas. Some have changes of curvature, so that the lines of thermo-electric power would be broken, whilst it is noticeable that antimony has two neutral points, and all specimens of bismuth exhibit a sudden break at −80deg. *pt.* The same authors have investigated the resistance in the case of three samples of bismuth: (1) commercial pure bismuth (A); (2) and (3) pure samples specially prepared (B and C), the temperature varying from 95deg. to −235deg. (platinum degrees). In each case the specific resistance at first diminishes, a minimum being reached at −50deg. *pt.* (B), −83deg. *pt.* (C), and 0deg. (A); after this the resistance increased, the temperature coefficient being negative. In the case of the commercial bismuth (A), a maximum was reached at about −200deg. *pt.*, after which the temperature coefficient was again positive; but in the two pure samples no such maximum occurred, neither was there any indication that a maximum would be reached. It is noticeable that the change in the temperature coefficient of the pure bismuth (especially C) occurs at about the same temperature as that of the discontinuity in the thermo-electric power. It is also found that the effect of a magnetic field on the resistance of the metal is very much increased by reduction of temperature, an increase of 5 per cent. due to a magnetic field reaching 25 per cent. at the temperature of liquid air.

The Electric Railway Chronograph.—The running of a street car from the time it leaves the terminal shed to its return is frequently supposed to be dependent entirely on the motorman and the conductor, but the movement of the car all the time is known to the superintendent in the central office. He simply consults a chronograph and immediately learns whether the cars are running regularly or irregularly; whether there is a stoppage at any point; how long it lasts; how many cars are blocked; and when the trouble is removed and the road begins operations again. This chronograph constitutes a sort of living map of the road, by means of which the superintendent can take a bird's-eye view of the whole operation of the line. If there is a bad break, he can send instructions to fill in with extra cars. If there is irregularity in the running time without good cause, he can check it, and, if necessary, trace the exact car which is responsible for the deviation from schedule time. The manner in which all this information is obtained is extremely simple. The chronograph consists primarily of a sheet of paper moving at a uniform rate under a series of pens or points operated by magnets. Each magnet point represents a point on the road, and each time a car passes this point on the road it makes contact, and the magnet point on the chronograph makes a mark on the paper. On the frame of the instrument is mounted a back roller to hold a supply of paper, the front roller on which to roll up the record, the top plate holding the magnet points, and the roller, which gives the time movement to the sheet. This top roller is a series of grooved wheels, one for each magnet point. The importance of this part of the device is obvious, since the movement of the sheet must be absolute and exact or there will be inaccuracy in the time record. This roller is actuated at the rate of one revolution an hour by a powerful clock movement. This gives the paper 4in. of movement in the hour, or 1in. for every 15 minutes. A line running on the one-minute schedule will, therefore, show 15 cars or prick marks to the inch, a five-minute schedule three to the inch, and so on. A break of 2in. would denote a stoppage of 30 minutes at that point. When the superintendent sees a regular, unbroken showing of points on the record he knows that the cars are all doing their full work. The record-sheets are dated and filed for reference, and in offices where the chronograph has been used since its introduction two years ago the company can instantly tell how the cars worked on any day in that time.

American Fire Office Rules.—The new rules agreed on by the Underwriters' National Electric Association have been published. The changes made in the rules, while considerable in number, are not radical, except in a few cases, and the following are some of the more important of them, and are given in the order of the sections amended in the present rules: The grounding of the frames of generators may be allowed when necessary by written permission. This change was made on account of the introduction of direct-connected and extremely large and heavy machines. Switches for motors must hereafter plainly indicate whether the current is on or off. Rules were adopted requiring wires to be protected from mechanical injury in buildings—where necessary, high-potential wires by substantial boxing, giving a reasonable air space, and low-tension wires either by boxing or by an approved iron-armoured conduit tubing. The mesh of wire netting for arc light globes should not exceed 1½in. Switches on hanger boards must cut out both poles of the lamp The use of wire smaller than No. 14 B. & S. will not hereafter be allowed except for pendant and fixture work. The rules for special wiring in breweries, etc., will require that joints and splices be avoided as far as possible, and that switches in damp places be mounted on porcelain knobs so as to give an air space behind them. It will hereafter be allowable to draw strings into conduits for the purpose of pulling in conductors, which should not be placed in the conduit until the mechanical work on the building has been completed as far as possible. Hereafter cut-outs will not be allowed in the canopies or shells of fixtures. Circuits must be arranged so that no group of lamps (whether on the same fixture or not) requiring a current of more than six amperes will be allowed to be ultimately dependent upon one cut-out, except that special permission may be given in writing for departure from this rule in case of large chandeliers. Hereafter, except for pendants and fixture work, a solid rubber insulation, protected by durable braid, will be required for flexible conductors. Supports for motor ceiling fans must have an insulator interposed between them and the motor. Service switches must disconnect all of the wires entering the building—that is, on the three-wire system, all three wires must be opened by the switch. The use of brass-sheathed interior conduit and vulca tubing will not hereafter be approved for bushings. The use of incandescent lamps in series circuits for decorative purposes will be allowed by special written permission, when installed in a proper manner. Rules for electric heating apparatus were adopted, which will require, in addition to the general wiring being done in accordance

Digitized by Google

with rules, that the switches shall plainly indicate whether the current is on or off; that the attachment of the feed-wires be in plain sight; that stationary heaters be treated as stoves, and that the flexible conductor necessary for use with flat-irons and other devices of a similar nature shall have an insulation that will not be injured by heat, such as asbestos, which insulation must be protected from mechanical injury by a substantial outer braiding. The matter of obtaining more effective and more efficiently constructed devices for automatic safety cut-outs has been referred to the committee on testing with a request that they obtain all the information possible in relation to the proper construction of fuse blocks, length of fuses, and efficiency of fuse metal, and with relation to currents of various quantity and potential. A committee has been appointed to consider and report on the question of how best to guard against the hazard due to the possibility of the breaking down of the insulation between the primary and secondary transformer coils. This subject was considered of importance, in view of the tendency toward extremely high voltages in long-distance transmission. The subject of protectors which will obviate the hazard due to the liability of wires, such as telegraph, telephone, and similar wires becoming crossed with electric light or power wires, has also been referred to a committee.

Storage Battery Applications.—The *Electrical Review* of New York summarises a communication on "Past and Present Obstacles in the Storage Battery Development," before the American Institute of Electrical Engineers, as follows: Cessation of litigation and the development of the Planté type of cells make the storage battery outlook in this country much brighter; the cost of a guaranteed storage battery seems in many cases to be nearly equal to that of the direct generators to encourage their general adoption. A reduction in the cost would therefore open a large field, much larger than in proportion to the reduction; the renting of accumulators seems a commendable method of introducing them. Most of the diseases which storage batteries are subject to could be avoided or made much less disastrous by having large surfaces, small depths of active material, and free circulation. The first cost would be reduced, and the vexing question of the uncertain amortisation settled by a light, short-lived, cheap positive plate, and a cheap process of reconverting old into new positive plates. Storage batteries for slow discharges have been a success abroad; a very large additional field would be opened by a light, cheap, rapid-rate cell. The objection to a plate with a thin layer of active material is that it may not retain its charge as well as one with a thick layer of pellets, but in most cases in which rapid rates are desired or cannot be avoided, the small loss in standing is probably more than balanced by the fact that the plates are not injured by rapid rates. As a rule, long periods between charges go hand-in-hand with slow discharges, and less objection to great weight, while short periods between charges, high rates of discharges, and lightness usually go together. In conclusion, the writer of the communication took the opportunity of making the following recommendations in the interests of engineers who may have to calculate accumulator plants. That rates of charge and discharge be designated in hours and fractions, the current (or for power purposes, the watts) during that time being considered to be kept constant. There can then be no mistake as to what is meant, as this represents the time in hours during which a cell will continue to give a practically constant current before the voltage falls below its limit. That efficiencies and capacities be always accompanied by the corresponding rate in hours. That in giving an efficiency it should always be stated whether it is for ampere-hours or for watt-hours. That for portable batteries intended for power purposes the capacity be given in watt-hours instead of ampere-hours, and that the weight given be that of the complete cell ready for use, as distinguished from the weight of the plates alone. Mr. Arthur E. Childs contributed a communication on "The Storage Battery for Central Stations." He said the fact that storage batteries had reached a point of high efficiency and low cost of maintenance had stirred up engineers in their country to consider the application of storage batteries to their own plant, and thus the accumulator had assumed great importance at the present time, especially as power and light stations were so far developed that further increase in generating capacity meant large additional expenditure, and in many cases the rebuilding of the entire plant. In England and on the Continent storage batteries had been used in central stations for more than five years, and their utility and value were acknowledged throughout Europe. The great variations and fluctuations of the load on power circuits were among the greatest difficulties which engineers had to contend against, and the introduction of a storage battery into a central station acted in a certain sense as a buffer between the external load and the dynamos, taking the shock of the variations without throwing the same on the engines. As applied to power stations, and especially where water power was used, storage batteries were almost indispensable. With regard to illuminating plants their value was equally as great, as the charging of the battery could be done while the plant was operating at light loads. At the period of heavy load the battery was able to take care of the peak of the load, and also to operate the lights when few lights were being supplied from the station. The storage battery could also be used as a valuable adjunct to both power and lighting stations at points where it was difficult to maintain the voltage at periods of heavy load. A survey of the progress which storage batteries had made in European countries indicated no very great change in the principle of construction, but the results seemed to be rather due to a thorough analysis and appreciation of the requirements of each case. The great difficulty in America had been that engineers had not recognised a proper limit to the usefulness of a battery, but had in many cases far exceeded their specified limitation, and so injured the batteries and cast discredit on them. The batteries in use in Europe had shown grea endurance and solidity, from the fact that engineers had endeavoured to obtain long life and high efficiency even at the expense of increased first cost. Great progress had recently been made in the manufacture of the batteries, and manufacturers could now produce cells having almost any given capacity. The factors which tended to reduce the efficiency of a storage battery were due to a loss in voltage and in the quantity of current; but these losses were not so serious as in the past. Mr. C. L. Edgar, in a communication on "Practical Experience with Storage Batteries in Central Stations," classed their uses under four heads: (1) to carry the peak of the load at maximum hours, (2) to carry the entire load at minimum hours, (3) to act as equaliser or reservoir, and (4) for the equipment of annex stations. Mr. Nelson W. Perry, E.M., considered that they had a more economical method to hand than the use of storage batteries. He referred to the gas-engine. In the discussion which followed, the use of the storage battery was very favourably commented on, but the idea of the gas-engine for driving the generators did not meet with much approval. A simultaneous discussion on "Storage Battery Applications" took place at Chicago.

LECTURE XXI.

(Specially Contributed.)

Registering Ammeters.—These are instruments intended to keep a continuous record of the current in the circuit. One of the best known is that of Richard. Here we have an electromagnet, A B (Fig. 1), with an iron fan-shaped

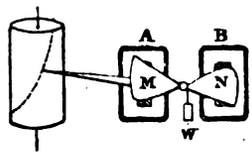

FIG. 1.

armature, M N, movable on its axle. When a current passes, the armature is attracted and turns about its axle. The motion is counterbalanced by a small weight. The armature carries a pointer, as shown, which is used to trace a mark upon paper carried by a cylinder moved by a clock-work arrangement. The indicator card made by the pointer can be read by reference to a graduated scale. Fig. 1A shows the complete instrument.

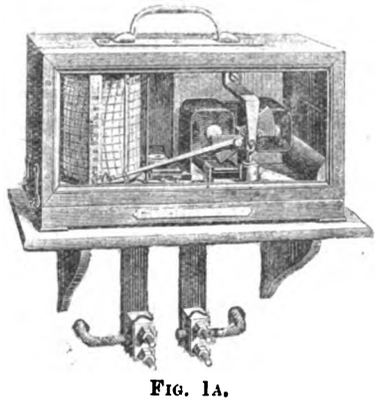

FIG. 1A.

Ammeter-Balance.—In this instrument the current through the coil of the electromagnet also attracts the armature, and the force of attraction is balanced by a weight which we can slide along a graduated scale. The position of the weight on the scale shows the current in amperes.

Electro-Dynamometers.—The instruments previously described are only useful for measuring continuous currents—that is, currents going in one direction; but we have also to deal with alternate currents—that is, currents going first in one direction, then in another. The instrument I am about to describe will do for either kind of measurement. We have seen that every conductor carrying a current is surrounded by its magnetic field, and the field of a current in one conductor has its effect upon the field of another conductor just as it has upon the field of a magnet. If, then, we have a conductor, A B, and another, F F, and pass currents through these conductors, the interaction between the fields will be to tend to place the conductors so that the lines of force of the two fields are parallel. This tendency may be represented numerically by the product of the two currents—$C \times C_1$. Thus, if the conductors are so arranged that same current goes through both conductors, the tendency will be equal to the square of the current.

If a current of x amperes goes through one conductor, A B,
and a current of y amperes goes through the other conductor, F F,
the strength of the force tending to bring A B and F F parallel is $x \times y$, or $x\,y$.

If the current in A B $= x$,
and the current in C D $= x$,

then the force $= x \times x = x^2$.

This means that if the fields of two conductors interfere, the force tending to bring them parallel is equivalent to the product of the currents in each conductor. When, therefore, the current in each conductor is the same, the force is equivalent to the square of the current.

If, by means of the torsion of a spring, the movable coil is kept at rest, the angle through which the spring has to be moved will be the measure of the square of the current. The Siemens electro-dynamometer is the best known, and will now be described. In it we have two coils, one coil fixed containing a number of turns, and usually so constructed and connected with binding screws that more or less turns can be used according as the measurement in hand requires. Examine the diagram, Fig. 2. The inner coil, F F F F, represents the fixed coil of many turns, while the outer coil, A B, represents the movable coil, usually of a single turn. The coils are connected in series through the mercury-cup, H H_1 When a current is sent through the coils, as shown by the arrows, A B tends to move so as to be parallel to the fixed coils, and is balanced by the spring. Now examine the two illustrations of this instrument (Figs. 2 and 3). F F shows the fixed coil, A B the movable coil which carries a pointer, P, with a turn at the end to point to the division of the scale. The binding screws, 1, 2, 3, admit of more or less of the fixed coils being used in the reading. Suppose, now, the source of current properly connected to the binding screws, then the current traverses both fixed and movable coil, and the latter at once moves. The index of the movable coil is brought back to zero by turning the screw, S, so as to oppose its torsion to the force tending to move the coil,

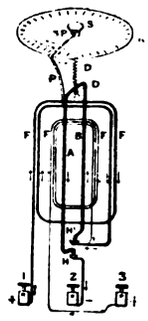

FIG. 2.

and the number of degrees through which the screw pointer, S P, is moved, in order to bring back the movable coil index to zero, must be noted. As has been said, the angle through which the torsion screw is moved measures the square of the current. The movable coil, having only one turn, is not much influenced by the earth's field, but solely by that of the fixed coil; hence there is no necessity to have the coil in a particular direction. To find the current in amperes, we have to find the square root of the angle and multiply by a constant.

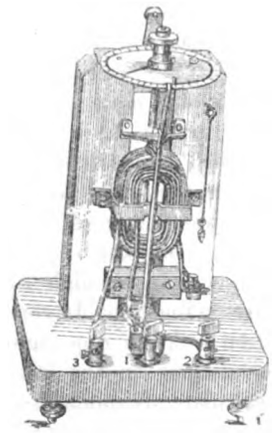

FIG. 3.

The constant used differs for each instrument, and is supplied by the makers. Usually the fixed coil really consists of two coils—one of large wire for heavy currents, the second of smaller wire for smaller currents, as is shown diagrammatically in Fig. 2.

Ammeters and Voltmeters.—The instruments hitherto described are for the measurement of current,

Digitized by Google

but we have also to measure pressure, and a little examination will show that the instruments to measure volts need not differ in principle, though they must in construction, from those to measure amperes. Keeping in mind that the test must not alter the thing tested, and that the introduction of any testing instrument into any circuit will alter the conditions somewhat, it can easily be seen that an ammeter must fulfil certain conditions altogether different from those necessary in a voltmeter. To use an ammeter, we put it in series with the rest of the circuit, so that the total resistance of the circuit is increased by the resistance of the instrument. If, then, the resistance of the instrument is large compared with the resistance of the circuit and the pressure constant, the circuit currents before and after the insertion of the instrument may differ considerably. Just examine a case or two.

Take a circuit having a resistance of two ohms and a pressure of 10 volts.

From Ohm's law $C = \frac{E}{R}$,

we get $C = \frac{10}{2} = 5$;

i.e., we get five amperes of current.

Now, suppose we try to measure this current with an ammeter having a resistance of two ohms. The insertion of this brings the circuit resistance to four ohms.

Then $C = \frac{E}{R}$;

$C = \frac{10}{4} = 2{\cdot}5.$

We have doubled the resistance and halved the current.

Suppose our circuit consists of 40 arc lamps in series, each having a resistance of five ohms, added to which the connecting wires, etc., gave further 10 ohms resistance to the circuit, or a total circuit resistance of 210 ohms. Let the pressure be 2,100 volts.

From $C = \frac{E}{R}$,

$C = \frac{2,100}{210} = 10$;

that is, we get 10 amperes as the current. Adding our ammeter of two ohms brings the circuit resistance to 212 ohms and the current to

$$C = \frac{2,100}{212} = 9{\cdot}9,$$

a very different state of things to the other case.

Let us see what information we can gain by an examination of the formula $C = \frac{E}{R}$,

where, as usual, C = current,
E = E.M.F., or pressure,
R = resistance.

If we add another resistance, r, then the denominator becomes $R + r$,

and $$C = \frac{E}{R + r}.$$

Those who have little algebraical knowledge may look upon formulæ like $C = \frac{E}{R}$ or $C = \frac{E}{R + r}$ as division sums.

Just like

$$24) 144 (6$$
$$144$$
$$\cdots$$

where we have a divisor 24, a dividend 144, and a quotient 6.

In the formula, C is the quotient, R or $R + r$ the divisor, and E the dividend. From our knowledge of simple division, we know that increasing the divisor decreases the quotient when the dividend is constant.

When we want to measure current we want to measure the real current in the working circuit; hence the ammeter or other instrument used must have a small resistance compared with the rest of the circuit—that is, the divisor must be increased by as small a quantity as possible. When we come to measure pressure something similar holds good, but here the current should be as small as possible and the resistance as large as possible for that particular pressure. We have seen that mechanical pressure applied to a body gives it motion—of course, understanding that the body is not too large for the pressure. We can get the value of the pressure from a knowledge of the mass of the body and the velocity it acquires under the action of the pressing force, but that is not so easy a way to find the value of the pressure as is the increasing and increasing the mass causing motion till you come to the point where the addition of the slightest mass prevents motion. Let me illustrate this by a diagram.

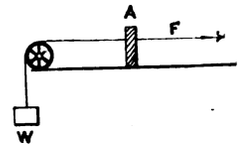

Fig. 4.

In Fig. 4 let A represent a body acted upon by a force, F. On the other side of A, I harness a weight, W, and change that weight for a larger and a larger till the force, F, is just counterbalanced, and A does not move. I can at once say that the force, F, is equal to a gravitational force of so many pounds. This balancing method is most useful in many directions. The grocer balances unknown weights with known weights, and the unknown remains unknown no longer. Similarly, we might balance electrical pressures by opposing known pressures to unknown pressures through a resistance. So long as pressures differed there would be a current in one direction, but when the pressures were equal there would be no current. This method is sometimes adopted, but not often, as it is inconvenient. Hence the more convenient method—

$$C = \frac{E}{R}, \text{ or } C \times R = E$$

is used.

But, again, we must remember that the E.M.F. does not remain constant if we take too large a current. Consider once more the water analogy. Let us have a reservoir, H, with water at the level, L (Fig. 5). Then A L is the head of

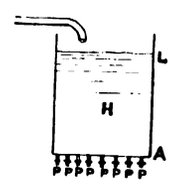

Fig. 5.

water. Suppose water can be supplied to the reservoir by the pipe, P, at the top, and taken from the reservoir by the pipes, P P P P, at the bottom. The available head of water is A L. If I open all the pipes at the bottom the rush of water out is too great for this head to be kept up, and this great rush out of water is somewhat like too large currents of electricity—in both cases it is difficult to keep pressure constant. Thus, what we do is to take a small current.

Now, in the formula, $C \times R = E$.

If C is made smaller and smaller R must be made larger and larger—that is, a small current requires a larger resistance in order to correctly measure E.M.F.

An ammeter, then, of large resistance will enable us to measure E.M.F., and many voltmeters are constructed upon the same principle as ammeters, but wound with wire of much greater resistance.

The equation $C = \frac{E}{R}$ may be read in another way—viz., that C varies directly as E and inversely as R. So that if we increase or decrease E in any way, C will increase or decrease similarly if R remains constant.

Now, the resistance of a voltmeter, or, for the matter of that, an ammeter, remains constant, leaving for the moment the change of resistance due to rise of tempera-

Digitized by Google

ture. Take an ammeter of high resistance and join by conductors to its terminals the two points in the circuit the difference of potential between which we want to know,

then $$C = \frac{E}{R}.$$

Take the same instrument and join any other two points similarly,

then $$C_1 = \frac{E_1}{R}.$$

Thus the indications of current, C and C_1, will be proportional to the differences of potential, or pressure, and will give this difference in volts if the scale divisions be marked for this purpose.

If in the second instance the current C_1 is 2, 3, 4, or n times or $\frac{1}{2}$, $\frac{1}{3}$, or $\frac{1}{n}$th times the current C in the first instance, then E_1 will be also 2, 3, 4, or n times, or $\frac{1}{2}$, $\frac{1}{3}$, or $\frac{1}{n}$th times E in the first instance.

All, then, we have to know to make a scale is *the* E that will give a current C.

When a current of 2 C is observed, then the pressure is 2 E, and so on.

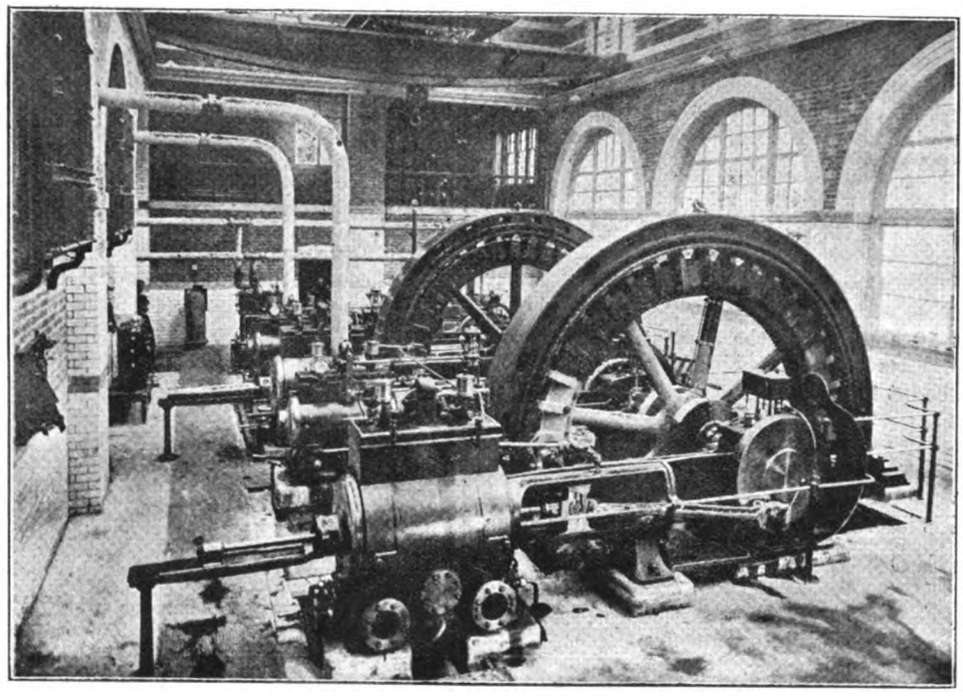
AYR ELECTRICITY WORKS.

The opening ceremony in connection with the installation of the electric light in Ayr was performed on Wednesday afternoon by Lord Kelvin, F.R.S. Provost Willock presided, and there was a large attendance, including a deputation from the Town Council of Glasgow, the Provosts of Kilmarnock, Irvine, Girvan, and Govan.

Provost WILLOCK, in introducing Lord Kelvin, gave a short *résumé* of the history of the work, and then called upon Lord Kelvin, who, he said, had come there, together with Lady Kelvin, at considerable inconvenience to himself.

Lord KELVIN expressed the great pleasure it afforded him to be present to witness the opening of such an exceedingly interesting application of science as the application of electric lighting in the town and district of Ayr. Long before such an application of electricity became a reality, it was a dream of science that electricity would at some time or other be applied for lighting and other purposes, and that day they would see its realisation in Ayr. They had to carry their minds back a good way to find the first use of electricity, but at that early date it could not be used for lighting houses. The only kind then in use was that used for lighthouses—*i.e.*, the very old discovery of Sir Humphry Davy—the electric arc light. They had to go back for a period of 60 or 70 years for their knowledge of the electric arc light. Going back 30 years, however, would suffice to take them to the time of the first useful or practical application of the electric arc light, of which he might say that even then the only practised application of electric light was still for lighthouses and very little indeed for other purposes until many years after. Fifteen years ago there came a great development of discovery in connection with the light, and that was the practicability of applying the light to other purposes for which it had not been previously designed. It was then realised that the application of the light which they were going to see that day was practicable. That discovery was chiefly due to Swan and Edison, and culminated in the Swan-Edison lamp. He congratulated the town of Ayr that it should at so comparatively early a day have come forward and that its Municipality should use electricity in that practical way. The provost had told them how they came to take the matter into their own hands, and in that he thought they had acted wisely. He was quite sure the people of Ayr at present thought their Council had done right, and he hoped and believed that after two, three, and even twenty years they would know from actual experience that the confidence they had placed in their Council had been well founded. The work of producing the engines, dynamos, and arrangements for transmitting the light from that building over the town had gone on very vigorously and successfully until it had culminated in that successful opening. That was not the time to speak of plans and machinery. Different places had different plans and different machinery, and in different countries there were large varieties of mechanism, steam-engines, and electric engines which had been chosen to do the work of electric lighting. Ayr had the benefit of 15 years' experience from the beginning of this light, and yet it was very early among the towns of Scotland to take up the matter, but under the able guidance of Mr. Hammond the work had been carried out in a manner he believed would be a credit to all concerned. It was a treat to him to see these grand engines, two of which were ready to give 100 kilowatts of power, and it gave him great pleasure to declare the electric light installation of Ayr open.

Bailie URE (convener of the Lighting Committee), in the name of the Corporation, presented Mrs. Willock with a gold bracelet as a souvenir of the occasion. Provost Wil-



View of the Engine-room at Ayr, showing the Flywheel Alternators.

Digitized by Google

lock thanked Bailie Ure and the Council, on behalf of Mrs. Willock, for the memento, and said he was sure Mrs. Willock would look upon it with great pleasure in days to come. Mr. Robert Hammond (consulting engineer) then moved a vote of thanks to Lord Kelvin.

Lord KELVIN briefly returned thanks, and Mrs. Willock then started the machinery amid cheers. The Council afterwards entertained a company of guests to dinner in the town hall in the evening.

ARTIFICIAL ICE FLOOR FOR SKATING.

The production of a really good ice floor has for years been the aim of many engineers, but experiments on a large scale have been few owing to their costly nature and the large amount of plant required. A new system has recently been laid down at the Hengler Circus in Argyll-street, Oxford-street, the building now being called "The National Skating Palace." There are many novel features in the construction which are worthy of notice as likely to give a more uniform hardness to the sheet of ice produced, and also to result in a ready method of keeping all parts of the ice floor at a uniform temperature. This new system, which is under patents owned by Messrs. Tyler and Ellis and Messrs. J. and E. Hall, has the following essential details. The floor itself consists of a uniform sheet of ice 4in. thick, which rests on rectangular steel tanks about 2in. in depth. Through the flat closed tanks a brine solution is passed, which by its low temperature keeps the ice at the freezing point. The temperature of the brine passing out of each of these tanks is measured on thermometers near the regulation stop-valves, and if the delivery water from one is found to be warmer than the rest a quicker circulation of salt water is given. The actual temperature of the brine is about 26deg. F., the difference of temperature between inlet and outlet being only 3deg. or 4deg. F.

Under the cooling-tanks there is an insulating air-space of about 12in., then a matchboarding floor covered with lead, which rests on a layer of charcoal about 6in. thick placed on the concrete foundations. These flat tanks under the ice give a more uniform temperature, and therefore more uniform hardness, than some older systems where pipes are actually embedded in a thicker layer of ice. Any leakage of the cooling solution from such pipes is apt to discolour the ice and make it rotten. Also, owing to the great thickness of ice required to cover the pipes and to make up a level surface, the ice becomes very solid and heavy, and hence more liable to crack.

The water-tank of the Tyler and Ellis system also gives a certain elasticity to the ice which is more like that experienced when skating on a frozen pond. The refrigerating machinery at the National Skating Palace is worthy of special notice. Below the building is the boiler-room, with its battery of three 40-horse locomotive boilers, by Messrs. Davey, Paxman, and Co., of Colchester. Either two of these boilers are capable of supplying all the steam necessary for the various engines. This boiler-room is shut off from the engine-room proper by a brick wall, so that no dust may be carried over the machinery.

The machinery in the engine-room consists of two main 50-h.p. refrigerating engines and compressors, standing along one side of the gangway, while the two sets of electric light engines and dynamos are on the other. These refrigerating engines are of Messrs. J. and E. Hall's carbonic-anhydride system, and are tandem compound horizontal condensing engines. Each engine is capable of maintaining the ice surface in perfect order, and together they can freeze an entirely new floor 4in. thick in 24 hours. These carbonic-anhydride machines are superior to the older forms of refrigerating machines, in which ammonia and other chemicals were employed, owing to the far greater refrigerating effect of carbonic anhydride and to its being an odourless innocuous gas, which latter is of the greatest consideration in or about a place of public entertainment.

The actual routine of this refrigerating operation is as follows: The CO_2 is drawn from the evaporating-tanks and compressed. It is then passed into the cooling-tank, when at a temperature of about 48deg. F. it assumes the liquid form. From these condensing-tanks, which are cooled by circulating water, the liquid carbon anhydride is evaporated in two other large tanks through pipes in which the brine is circulated. The actual temperature in these evaporating-tanks was 17deg. F. when our representative visited the engine-room. The brine is thus cooled; but it will be noticed the carbonic anhydride is only used in the engine-room, the brine being the medium for cooling the ice floor by conduction.

In this installation the whole of the steam used in the various engines is condensed, and for this a large volume of cold water is required to absorb the heat of the steam, as well as to cool the gas in the carbonic-anhydride condensers. As this amount of water, if taken from the water company's mains, would be a matter of great expense, the directors decided to sink a well into the deep chalk to ensure a large supply of pure water. This well has been sunk at the far end of the engine-room to a depth of nearly 400ft. from ground level, the work being carried out by Messrs. Thos. Tilley and Sons, of Walbrook. The deep-well pump, which is capable of delivering upwards of 5,000 gallons per hour, was also supplied and erected by the same firm. This pump is driven by belt from a line shaft running overhead, and this shaft also drives the brine and water service pumps.

All the water delivered by the deep-well pump is first passed through the carbonic-anhydride condensers, where it is warmed through absorbing the heat from the compressed gas delivered into these condensers from the main refrigerating engines. Having passed through these condensers, part of the water is used in the main engine steam-condensers and for feeding the boilers, and part for the electric light engine condensers, the remainder being pumped to tanks on the roof for the general service of the building.

The condenser for the electric light and auxiliary engine is of the type known as an evaporator-condenser, and was supplied and erected by Messrs. T. Ledward and Co., of Queen Victoria-street. The pipes to this condenser are so arranged that the exhaust steam from the electric light and auxiliary engines may be turned into the condensers of the main refrigerating engines, and *vice versâ*, in the case of any breakdown.

The contract for the electric lighting machinery was placed with Messrs. Crompton and Co., Limited. Altogether, the lighting arrangements comprise the use of some hundreds of incandescent lamps, and 26 arcs, which are supplied with current by two 30-unit shunt-wound dynamos, driven with belts by two 56-i.h.p. vertical compound-condensing Sissons steam-engines, which take steam from the same boilers as the refrigerating plant.

Some interest is attached to the method of wiring that has been adopted—namely, Mavor and Coulson's concentric system, which is the subject of a paper now under consideration at the Institution of Electrical Engineers.

The floor and the whole of the machinery have been carried out to the designs and under the superintendence of the company's consulting engineers, Messrs. A. H. Tyler and J. S. E. de Vesian, A.M.I.C.E.; the company's consulting electrical engineer being Mr. C. Orme Bastian.

THE BERRENBERG METALLIC VACUUM PUMP.

It has been repeatedly asserted that the invention of the Sprengel pump brought the incandescent lamp within the range of possibility. With the highest vacuum previously attainable the carbon filaments would not last more than a few hours. As soon as the incandescent lamp was found to be a commercial possibility and a success, many inventors strove to perfect the mechanical pump as a more rapid means of exhausting the vast number of lamps required All the first attempts in this direction ended in failure, and it became almost a foregone conclusion that mechanical pumps were useless except to exhaust the bulk of the air from the bulbs before flashing the filament, and again before connecting them to the mercury-pumps. One of the early workers in this field did not, however, accept the general con

Digitized by Google

clusion. We refer to Mr. A. Berrenberg, of Boston, who commenced his attempts to build a satisfactory pump in 1885. By gradual improvements, he succeeded in 1888 in producing a sufficiently good vacuum by mechanical means as to attract general attention.

This pump was capable of making a vacuum up to the height of the barometer and of maintaining it. But as some kind of a fluid had to be used, it was found that the vapour from this fluid destroyed the lamp. This induced Mr. Berrenberg to design another pump, and it was constructed in such a way that this vapour could not enter the lamps. This second pump was successfully put to work in April, 1890, and was described in the issue of the *Electrical World* for the 26th of that month. The author there says: "The perfection of the work depends upon the radical departure from the mechanism of the old air-pump. This departure is simple in principle, and the reason for its effectiveness is plain. The device adopted is of forming a vacuum jacket around the working cylinder, so that whatever leaks in around the other side of the box (which is closed with oil, as in ordinary air-pumps) is promptly pumped out by the subsidiary cylinder. The difference of pressure, therefore, tending to cause leaks in the joints and valves of the working cylinder can be reduced to a quantity almost negligible, and the leakage almost disappears." This pump was used in America from that date up to the present time, but the lamp patents tended to restrict its universal application. In the meanwhile the inventor continued to make improvements which are all included in the pump which is now erected at 4, Huggin-lane, Queen Victoria-street, E.C., and of which we are able to give the three illustrations herewith.

The advantages of a good vacuum are now generally understood, and the fact is recognised that the Sprengel pump will give good results. The only consideration is that valuable time is taken to produce the best results, and hence the vacuum in a commercial lamp is not as a rule equal to that which would be attained with unlimited time. Even as it is, the cost of exhausting the lamps forms a fairly large proportion of the total cost of the lamp. Another point in which advantage is gained by the mechanical pump is in the blackening of the lamp globes after use.

Prof. B. F. Thomas, in his paper communicated in 1892 to the American Institute of Electrical Engineers on the test of a large series of different makes of lamps, says: "When the sorting and grading of the blackened lamps was satisfactorily completed, it was remarked that the two lots which were least blackened were of the makes which are advertised as exhausted by mechanical pumps. That they should both be so much alike in blackening, and both only one-half as much blackened as the least blackened of the mercurially-exhausted lamps is, to say the least, worthy of notice. It is, of course, not established that the observed freedom from blackening is due to the absence of mercury vapour in the lamp, as the makers claim, but if investigation should establish the claim the mercury-pump will probably become once more a laboratory instrument."

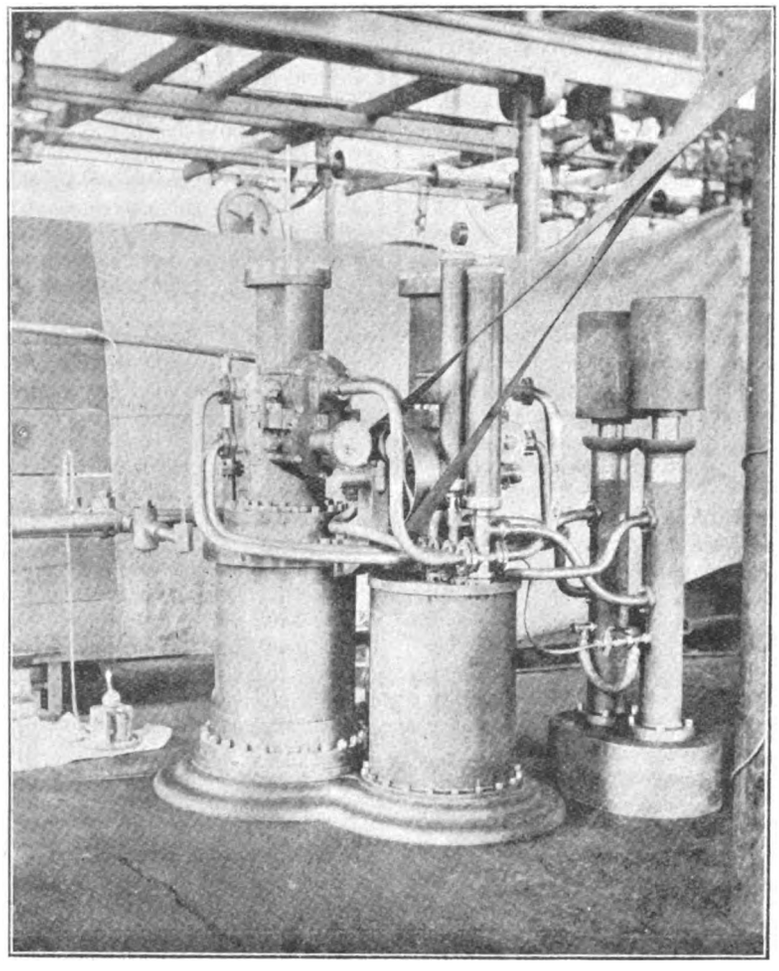


FIG. 1.—Perspective View of the Berrenberg Metallic Vacuum Pump.

The percentages of the maximum blackening observed in the lamps tested by Prof. Thomas ranged as follows: 10, 12½, 25, 28, 30, 32, 35, 42, 45, 50, 75, and 100 per cent. The first two—*i.e.*, 10 per cent. and 12½ per cent.—were observed in mechanically exhausted lamps. The mechanically exhausted lamps were treated by Mr. Berrenberg's pumps.

Leaving these historically interesting facts, the present pump is shown in perspective in Fig. 1, while Fig. 2 shows an elevation, and Fig. 3 a section through the pump. The chief difference between this machine and the pump of 1890 lies in the fact that the motion of the pump pistons is now effected hydraulically instead of by cranks, as in the older types. With air-pumps intended to produce a highly attenuated vacuum, it follows that the end clearances must be reduced to as nearly an actual fit as possible. For this reason the ends of the cylinders and piston are coned and ground to absolutely the same contour. It is then impossible to use the common reciprocating gear, and

Digitized by Google

the requisite flexibility was in the older pumps obtained by a compressible connecting rod. It is found, however, that fluid pressure is both more convenient, as also more certain in effect. In the section (Fig. 3) the upper two cylinders form the hydraulic mechanism for moving the two concentric pistons of the air-pump. As will be seen, the larger piston forms the cylinders for the inner piston. The action of the pump is as follows, commencing from the position shown: The two pistons move up together, and thus the opening from the lamp main is uncovered by the large piston. The inner piston, travelling through a longer stroke, delivers air abstracted from the lamp on the previous up stroke into the space above the piston. The outer piston previously delivers a certain amount into the space above the cylinder through the valves shown. This space is connected to the preliminary vacuum pump, and hence no increase of pressure is obtained. In fact, there is no atmospheric pressure anywhere within the air-pump. The fluid used in the upper cylinders for working the pump is a non-volatile oil. The force pump for maintaining the pressure on it is shown in the foreground in Figs. 1 and 2. The two accumulators shown in Fig. 1 are used to keep the pressure constant and to prevent shock at the end of the stroke. The great feature in the construction of these pumps

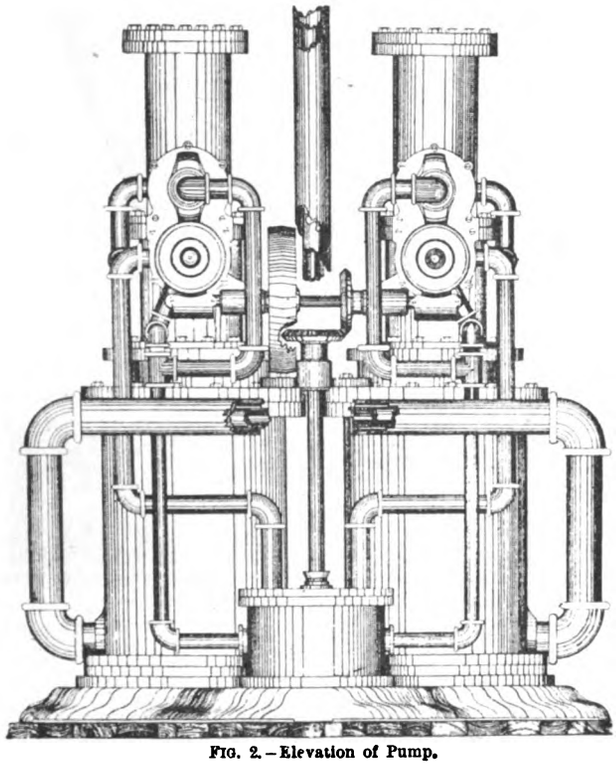

FIG. 2.—Elevation of Pump.

and the whole system is the excellence of the mechanical construction. The pistons and cylinders are made of welded steel rings, and then hammered out to the required diameter to ensure uniform density and freedom from air-holes. The work is then accurately turned on a lathe, the finish being given by an emery-wheel to ensure truth in every part. The other details of the pump will be gathered from the illustration.

Coming now to the practical work done by the pump in Huggin-lane as verified by us, the pump is connected to a duplex system of pipes, one branch of which is supposed to be exhausting, while lamps to be treated are being attached to the other branch. These pipes can be partly seen in Fig. 1. At Huggin-lane only one branch is erected, owing to the limited space sufficient for test purposes. It consists of one main pipe and eight side tubes, each controlled by a valve. Each side tube has sockets provided for four main lamp connections. The junction in Fig. 1 only shows one such socket. These sockets are tapered to receive glass plugs with cocks, to which are blown a series of lamps. The whole of the glass plugs are emery ground to an exact taper, so that any plug will make an absolutely air-tight connection with any socket. The whole of the tubes connected to the pump are lagged by the same non-volatile oil that is used in the pump. This is done by surrounding them by a second system of steel pipes, which, of course, is the one seen in the figure. The intervening space is then filled with the liquid.

The equivalent number of 16-c.p. lamps connected in our presence was 265. These were roughly exhausted by an ordinary air-pump and then connected to the final pump. In six minutes the McLeod gauge showed that $\frac{1}{50,000}$th of the atmospheric pressure remained inside the bulbs. The bubble left in an ordinary-sized lamp bulb when filled with mercury was then of the same size as that in a lamp exhausted by mercurial pumps, which Mr. Berrenberg assured us was about the best he has found.

To check this, we brought a commercial lamp at once from an independent source, and on breaking it under mercury found the residual bubble to be considerably larger. The reading on the McLeod gauge at this point was 10mm. After 20 minutes this value was reduced to about 1mm., corresponding to a pressure of $\frac{1}{500,000}$th of an atmosphere. As will be gathered from the above, this is 10 times better than that in the ordinary lamps exhausted by mercury-pumps. Thus, both in speed and quality this pump gives most excellent results, and the inventor is to be congratulated on the success which has followed the long and arduous labours. The perfect interchangeability

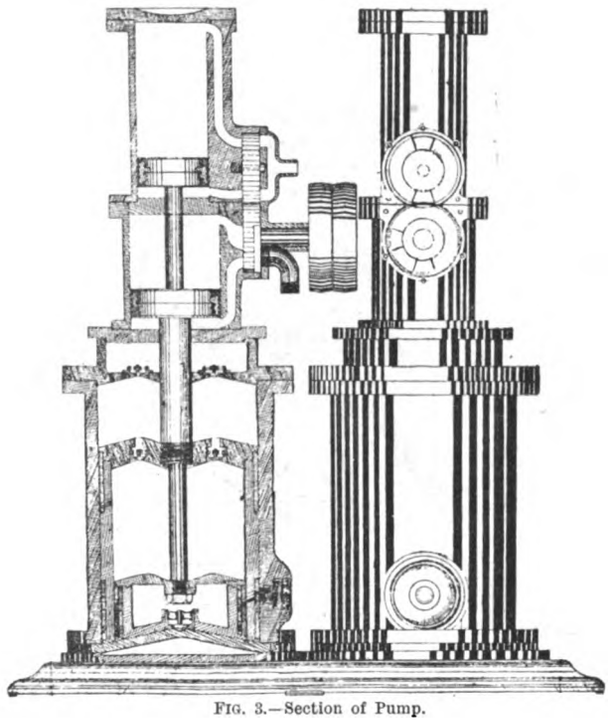

FIG. 3.—Section of Pump.

of parts must be seen to be believed. The fact that the system of pipes and valves shows no appreciable leakage in 48 hours is a proof of the good results obtained. We shall await with interest the results of the attempt to get English lamp manufacturers to take up this method of exhausting their lamps.

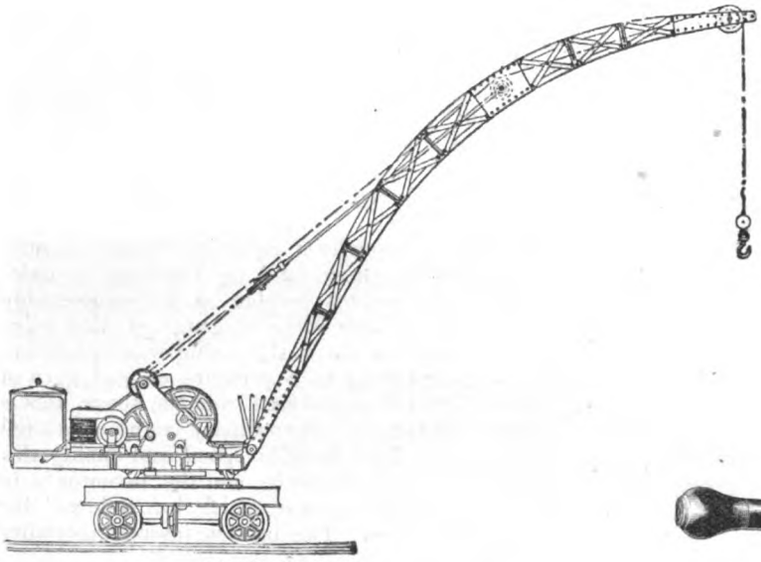
THE GENERAL ELECTRIC COMPANY'S 1896 CATALOGUE.

The new edition of this company's price-lists is bound up in a handsome medium quarto volume, containing about 1,000 pages and some thousands of illustrations, the various articles listed comprising practically every article required in the equipment and use of the now numerous branches of electrical science and the many practical applications resulting therefrom. Thus the articles listed vary from a countersunk iron screw up to a complete electric dog-cart with silk fittings, and, again, down from an electric piano, which we presume is musical, to an electric bell at 2s. 9d., which decidedly is not. The range of subjects has been met to a certain extent by subdividing the matter into eight sections, although in certain cases it

Digitized by Google

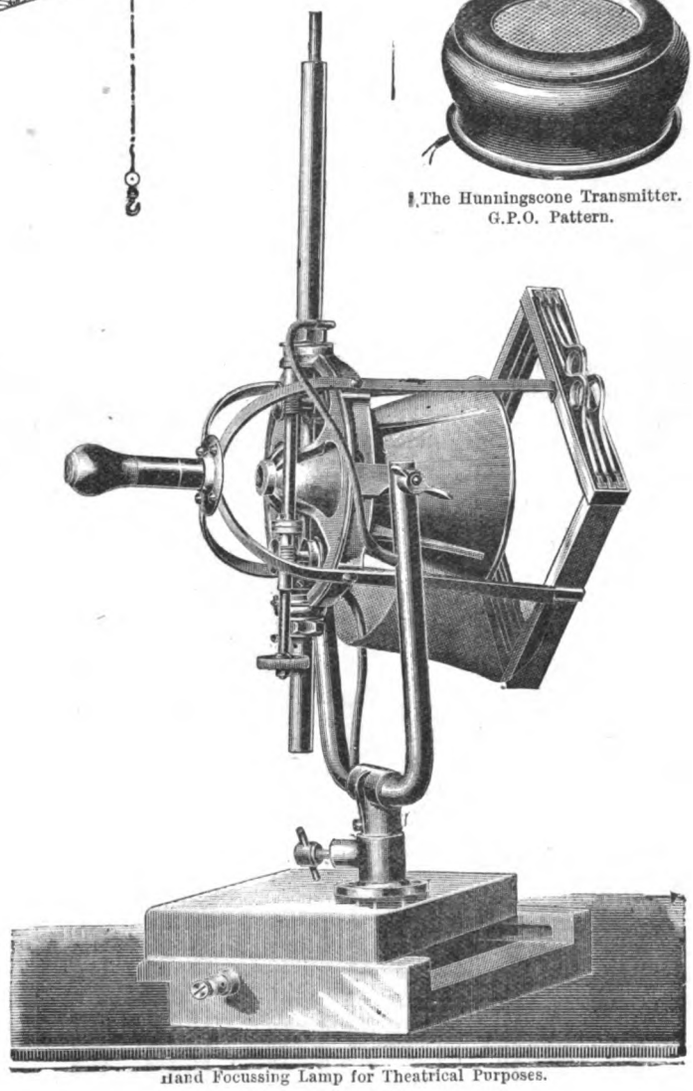
is not easy to classify correctly. Thus the electric piano mentioned above is placed in the heating and cooking section, and is sandwiched in the index between an electric oven and an electric saucepan. We are also glad to note that now only certain types of transformers are heating apparatus. In the early days nearly every transformer was a capable heater of itself and its surroundings.

The section A, dealing with electric plant, contains 79 pages and 105 illustrations. It comprises a full price-list of engines (steam, gas, and petroleum), boilers, turbines, waterwheels, steam dynamo sets, dynamos, accumulators, transformers, alternating-current and multiphase apparatus and accessories for transmission of power, electric welding, and central-station stores, meters, instruments, etc.

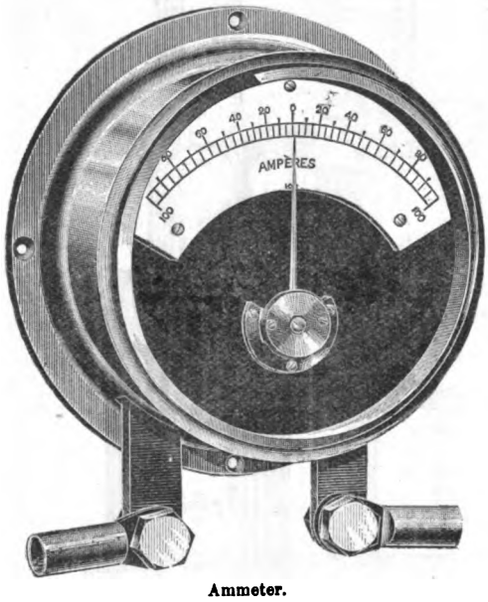


Electric Jib Crane.

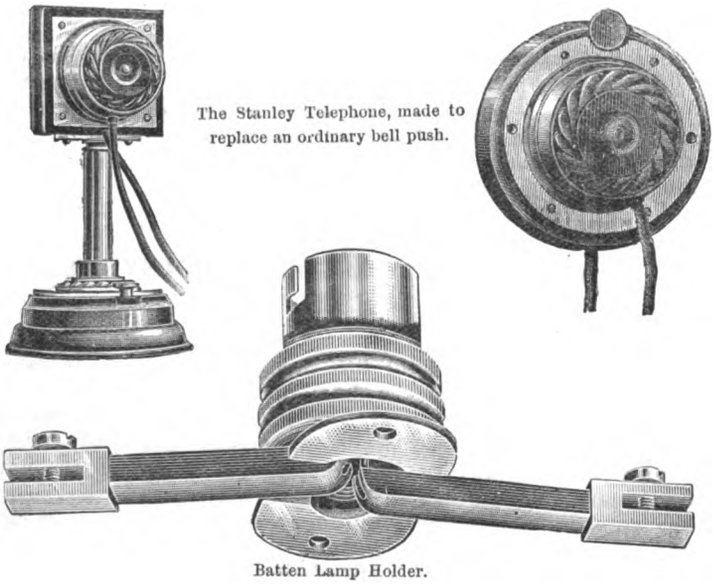
The Hunningscone Transmitter. G.P.O. Pattern.



Hand Focussing Lamp for Theatrical Purposes.



Ammeter.



The Stanley Telephone, made to replace an ordinary bell push.

Batten Lamp Holder.

Electrical Dog Cart.

Digitized by Google

The next section refers mainly to house wiring and the thousand different articles directly connected therewith, such as cables, wires, lamps, switches, fuses, casing, tubing, etc. The stage lamp illustrated below comes in this section. It is a hand-feed focussing lamp, with arrangements in the front for interposing coloured glass before the beam. This class of lamp is being used largely in London theatres. The catalogue also shows that the company stock accessories for wiring on any system, whether casing, tubing, or concentric. The batten holder for theatre-lighting purposes is another new item in this issue.

Section K (telephones and telegraph) covers the ground of practical telephony up to the most recent and approved inventions. The "Hunningscone" telephone is shown, as are also the Stanley and other telephones, both in detail parts and also as arranged in complete systems. The numerous diagrams for wiring and installing telephones and estimating costs given here enables even a novice to understand a telephone installation.

Section M, on motors, is devoted to direct and alternating current motors and their application. There is in this section necessarily a very full explanatory text in which the principle, construction, action, and efficiency of the electric motor are explained by the aid of excellent diagrams and tables. The constructive portion also includes directions for installing electromotor plant; direct-current, alternating, three-phase and polyphase motors of various powers are tabulated and described; and we believe that this is the first English catalogue to publish the prices of three-phase plants. The various appliances for which motors can be used are described, and many illustrations are given. The other sections are headed "Electric Bells, etc.," "Medical Apparatus," which includes patient (*sic*) batteries, "Fixtures and Glassware," and "Cooking and Heating." This last section, although small at present, is expected to do great things for the central-station engineer in the future. The general get-up of the catalogue is good, and the index appears to be accurate and convenient.

In this catalogue one great advantage is that each article is illustrated by an excellent and clear woodcut, which, in almost every instance, has been made to a uniform scale of reduction. This enables one to form a very accurate idea of the size of an article, and is particularly useful in selecting electric light fittings. The prices are placed under every article, which enables one quickly to ascertain the price without having to turn back to ponderous lists.

The technical information given in the appendix and elsewhere is, on the whole, correct and very useful; but the comparison between the cost of gas and electric lighting in small installations is misleading, as the cost of labour is omitted. We must congratulate the General Electric Company on their production, and trust that the return will be in proportion to cost incurred.

We note that the nominal charge for this large volume is 10s., but that the money is refunded if orders are obtained through it.

CORRESPONDENCE.

"One man's word is no man's word,
Justice needs that both be heard."

THE UNIQUE SWITCH.

SIR,—In conversation with some of my clients I learn that someone is spreading a report in the trade to the effect that I have given up making my "Unique" pattern switch; and I shall be much obliged if you will be kind enough to allow me to contradict this rumour in your valuable journal. It may have been originated by someone having obtained the knowledge that the "Pioneer" type of switch is still enjoying a good sale, and I have for that reason, and at the wish of some of my clients, reconstructed same, and hope in a short time to put it on the market at a popular price. But this has nothing whatever to do with the sale of the "Unique" switch, which is as good as ever.—Yours, etc., A. P. LUNDBERG.

DIVISION TABLE FOR A PHOTOMETER BAR.

For those who have to carry out photometric measurements, the table given below may prove useful. It has been compiled by Major Bagnold, R.E., to enable a draughtsman to lay out, by means of a beam compass, a scale for reading off results direct from a photometer bar of any length. In this way a great saving of time is effected when a large number of photometric measurements have to be made.

DIVISION TABLE FOR PHOTOMETER BAR.

Column I. gives ratio of light under measurement to standard light. Column II. gives fraction of whole bar measured from its middle point.

TO CORRESPONDENTS.

All Rights Reserved. Secretaries and Managers of Companies are invited to furnish Notice of Meetings, Issue of New Shares, Installations, Contracts, and any information connected with Electrical Engineering which may be interesting to our readers. Inventors are informed that any account of their inventions submitted to us will receive our best consideration.

All communications intended for the Editor should be addressed C. H. W. BIGGS, *139-140, Salisbury Court, Fleet Street, London, E.C. Anonymous communications will not be noticed.*

TO ADVERTISERS.

Advertisements should be addressed to the Publisher, 139-140, Salisbury Court, Fleet Street, E.C., and should reach him not later than noon of Thursday. **Special Terms** *for a series can be arranged on application.*

"SITUATIONS VACANT" and "WANT PLACES" Advertisements will be charged at THREE WORDS for ONE PENNY with a MINIMUM charge of SIXPENCE.

TO SUBSCRIBERS.

"THE ELECTRICAL ENGINEER" can be had by Order, from any Newsagent in Town or Country, and at the various Railway Stations; or it can, if preferred, be supplied direct from the Office on the following terms:

	3 months.	6 months.	12 months.
United Kingdom	3s. 3d.	6s. 6d.	13s. 0d.
Other Places	4s. 11d.	9s. 9d.	19s. 6d.

(Post Free, Payable in Advance.)

Cheques, Post Office and Postal Orders for Subscription and Advertisements should be made payable to C. H. W. BIGGS, *139-140, Salisbury Court, Fleet Street, London, and be crossed "Union Bank."*

BOUND VOLUMES.

Vol. XV. of new series of "THE ELECTRICAL ENGINEER" can b had bound in blue cloth, gilt lettered, price 8s. 6d. Subscribers can have their own copies bound for 2s. 6d., or covers for binding can be obtained, price 2s.

A LESSON OF THE MOMENT.

Such is the headline to a letter of Mr. George Baden-Powell given in the *Times* of Tuesday last. Mr. Powell writes as follows:

"Sir,—At the moment we are all of us painfully anxious for prompt and unadulterated telegraphic news from South Africa, from Venezuela, and from other places where there is trouble. Still greater would be our anxiety and our need in time of actual war. The public will do well to bear in mind the present condition of our telegraphic connections.

"In regard to South Africa, the Aden-Zanzibar cable happens to have broken at an inopportune moment; considerable delay occurs on the West Coast route. But all these messages, as well as those to and from the Ashanti expedition, have to pass through foreign territory.

"Again, telegraphic connection with British Guiana, with all our Western Indian possessions, with our fleet in the West Indies, is maintained by means of landlines across Cuba and across the United States, lines subject to the necessities of local combatants or others who might be hostile to us.

"The remedy is simple—viz., to hasten the inevitable completion of two projected all-British direct cables. It is an axiom of to-day that submarine cables, made and laid with all the latest appliances, are certain to pay for commercial purposes; for State and strategic purposes they are indispensable.

"It is therefore to be hoped that in these moments of stress the public will read the lesson aright and see to it that the responsible authorities arrange to provide the two lines of cable communication which our empire may so urgently need in the future—viz., the shorter line from Bermuda to Jamaica and the longer line from Vancouver to Australia, with its continuation to Mauritius and South Africa.

"We shall thus obtain alternative and all-British means of communicating between all oversea points of the empire, invaluable alike for the commerce and security of all its parts."

The strategic value of cable communication with our Colonial Empire under the complete control of this country is what we have been arguing for years. From a purely commercial standpoint, there is much to be said in favour of numerous loops connecting port to port; but may it not be that even commercially inter-Imperial connections have a real value? The statistics that are brought forward by interested parties are of little use in this controversy, because, like the Chinaman who had never tasted roast pig, we know so little of the unknown—and the other statistics are unknown. Cables are now very much like railways with main and branch lines, the main line being fed largely by business from the branches. One of the purely commercial arguments against the Pacific line has been that it is, or, rather, would be, wholly a main line, and that there would not be enough traffic to make it pay. We do not believe a word of this argument, for, in the first place, all the American traffic to the East now has to come *viâ* Europe and traverse various lines to its disadvantage. If there was a Pacific cable, all the American traffic to Australasia would go by it, and we fancy very much of the European traffic would follow suit. We hope to live to see the Pacific line, and do not mind prophesying that the moment it begins to work—nay, before it begins to work—the present cable ring will find the existing tariffs are far too high, and will make a considerable reduction. We venture to say the ring has never worked its lines economically—it has never tried to do so; its tariffs have always been excessive, and its monopoly has neither been worked for the benefit of shareholders or clients, but solely in the interests of an inner ring. If it were otherwise, we should be the last to condemn the policy of business first and strategy after. City men have not to trouble about strategic concerns—they have to earn money,

Digitized by Google

and part of the money they earn goes to pay specialists to consider strategy. The various Governments concerned, then, are in our estimation more to blame for not combining the two things when agreeing to pay subsidies. The Governments may be said to have, in the first place, to consider Imperial wants; and, secondly, commercial wants. The fact is, that the former very largely include the latter, and most unmistakeably Imperial wants ought to consider as imperative the means of communicating with our Colonies without the cognisance of foreign nations. Thus, if subsidies are to be paid at all, they should be paid to such concerns as can be controlled upon our own territory. Our advice would be for all Colonies and the mother country to give notice that subsidies would be withdrawn from the companies not complying with these conditions, and transferred to the companies complying with them. Most subsidies are terminable at the end of a certain number of years; let them terminate so far as the present recipients are concerned, and be handed over to those who perform similar work wholly within our own territory.

BUSINESS DURING 1895

(Continued from page 18).

J. E. H. ANDREW AND Co. write: "We find on referring to our books that during 1895 we have supplied a total of about 1,200 effective horse-power for generating the electric current, which would be about equal to 12,000 16-c.p. lamps. Among the great number of private and public installations for which we have supplied 'Stockport' gas-engines as the motive power during 1895 we find it somewhat perplexing to give examples, but we may mention that among public institutions supplied during the year are: 9 e.h.p., Sydney University; 9 e.h.p., Theatre Royal, Merthyr Tydfil; 13 e.h.p., St. George's Hall, Newcastle-on-Tyne; 19 e.h.p., Chadwick Memorial Schools, Newcastle-on-Tyne; 30 e.h.p., Belfast Art and Industrial Exhibition (sold *Northern Whig* newspaper offices); 42 e.h.p., *Citizen* Office, Glasgow (Messrs. Jas. Hedderwick and Sons); 42 e.h.p., Temple Press, Limited, Rosebery-avenue, London, E.C.); 7 e.h.p., Column Printing Telegraph Syndicate, London (charging accumulators), hotels, etc.; 30 e.h.p., Grand Central Hotel, Belfast (J. H. Greenhill, Esq., consulting engineer); 35 e.h.p., Three Nuns Hotel, Aldgate, London, E.C.; 10 e.h.p., Ridgway Hotel, Douglas, Isle of Man; 24 e.h.p., Junior Reform Club, Liverpool (Mather and Platt, Limited, consulting engineers); central station, 120 e.h.p., Brookline Gaslight Company, Boston, Mass., U.S.A. Co-operative stores: 30 e.h.p. (two engines 15 e.h.p. each), Home and Colonial Stores, Finsbury; 22 e.h.p., Nelson Co-operative Wholesale Society, Limited, Nelson, Lancs. Private residential installations: Dr. Hopkinson (of Messrs. Mather and Platt, Limited), Oakleigh, Timperley, Cheshire; Dr. Ballantyne, Darwen; Alf. Benn, Esq., Upper Syke, Clayton, near Bradford, Yorks; Messrs. Ernest Scott and Mountain, Newcastle-on-Tyne, for private residence; J. T. Sandell, Esq., 213, Selhurst-road, South Norwood; Mr. N. Kilvert, Brooklands-road, Brooklands; and T. P. Petrocokino, Esq., Sedgeley Park, Higher Broughton. Messrs. Mather and Platt were the consulting engineers in regard to the last two installations. All the foregoing have been supplied with engines for driving electrical plant, and we may say that we have also had engines at several exhibitions, shows, etc., during the year driving direct lighting. We have a good number of orders on hand at the present time, and we are very hopeful as to the prospects of 1896; and with special reference to gas-engines for electric lighting we are pleased to see that the use of them is decidedly on the increase, and we are of opinion that the gas-engine will in the future be more often used for central-station work. We may say that in addition to the engines delivered in the United Kingdom we have exported several large engines and a good number of smaller ones for driving dynamos, etc., on the Continent, which are giving great satisfaction. We are very pleased to be able to say that up to the present time we have turned out every year an increased number of engines, and a higher average horse-power; and from the orders we have in hand at present, and enquiries received, etc., we have every reason to hope that at the end of the present year we shall have again considerably increased our output of engines for electric work."

THE BRITISH INSULATED WIRE COMPANY say: "We have carried out contracts for the following electric supply works: County of London and Brush Provincial Company, Limited, St. Luke's and Clerkenwell, London Electric Supply Corporation, Notting Hill Electric Lighting Company, Limited; further extensions to the City of London Electric Light Company, Limited, Aberdeen, Altrincham, Blackpool, Bolton, Bournemouth, Brighton, Bristol, Cambridge, Dover, Edinburgh, Hanley, Huddersfield, Leicester, Oldham, Portsmouth, Preston, Salford, Sheffield, Southport, Worcester, Yarmouth, Sunderland, as well as the tramway work at Bristol, and the high-tension mains for the tramways at Dublin, and telephone cables for the English Government National Telephone Company. As regards the new year, we have a large quantity of work before us—contracts at Shoreditch, St. Helens, Wakefield, Harrogate, and other towns, besides extensions at many other places. A very large extension of the factory is in hand and nearing completion."

MESSRS. BROWETT, LINDLEY, AND Co. have very much increased their output of engines for electric lighting and other purposes during the past year; in fact, it has been the largest since they commenced business. To meet the increased demands a good many new machine tools have been installed, and others are now in progress. Their standard vertical electric lighting engines, chiefly for direct driving and use on shipboard, have furnished the firm with the bulk of their orders, something over 100 engines having been supplied. They have also had during the year a fair share of heavier and central-station work, amongst which may be mentioned the completion of the Salford electric lighting station contract, a 250-h.p. engine for Derby extension, and two 220-h.p. engines for Ealing extension; also three 350-h.p. and one 250-h.p. engines of the vertical compound type for the British Plate Glass Company, St. Helens, two of which are now installed, and the other two nearing completion. Also several engines from 100 h.p. to 200 h.p. have been delivered during the year, including two for Spain, one for France, two for Russia, and one for the extension of the lighting of Messrs. R. Haworth and Co.'s mill. The firm have also supplied the whole of the pipe work and the surface-condensing plant for the electric generating station of the Dublin electric trams, and also a surface-condensing plant to the Southport Corporation for their electric lighting

Digitized by Google

station. During the year also, two of their special horizontal high-speed engines have been supplied to the General Traction Company for driving the generators at the Coventry tramway station; also coupled electric light plants for the Waterloo and City Railway Company, London, and the Ravenhead Plate Glass Works, St. Helens. The company also report very satisfactory prospects for the new year; they already have several good orders to commence work with, and there is every prospect of another very busy year.

DRAKE AND GORHAM report that during the past year the firm have made the usual progress, and it has been found necessary to enlarge the offices to accommodate the additional staff required, as well as to increase the showrooms of the firm's specialities and fittings. The branch at Manchester has been exceedingly busy, and arrangements are being made for opening another branch at Glasgow to facilitate the carrying out of the Scotch business. Among the more important of the country installations in hand during the year may be mentioned: Crewe Hall, for the Right Hon. the Earl of Crewe, 550 lights (steam plant); Windlestone Hall, for Sir William Eden, 300 lights (steam power); Sir Williams Farmers, near Ascot, oil-engine; Major Kearsley, Nantwich; W. H. Oakley, Esq.; A. H. Brown, Esq., M.P., near Dorking, steam; J. Murray Johnson, Esq.; F. Bower, Esq., Farningham, water-turbine; Captain Ormrod, steam; W. Drury Lowe; Herbert Strutt, Esq., Belper, water-turbine; C. C. Wyllie, Esq., Esher, oil-engine: J. Van Raalte, Esq.; J. Cannon, Esq.; E. H. Hills, Esq.; Captain Boothby; W. Lancaster, Esq., etc. The following are some of the town houses: the Right Hon. Marquis of Lansdowne, Secretary of State for War; His Grace the Duke of Montrose, Pont-street; Devonshire House extensions; the Right Hon. Lord Wynford; Forbes Leith, Esq.; Sir Richard Quain, F.R.S., etc.; Sir William Power; Prof. Kennedy; Miss Talbot; Charles Lucas, Esq.; Major the Hon. E. R. Bourke; Admiral Bowden Smith; the Hon. Mrs. Hay; Claude Hay, Esq.; A. Strickland, sen., Esq.; A. Strickland, jun., Esq.; Colonel Gascoigne; G. D. Faber, Esq; J. S. Buckingham, Esq.; J. Beck, Esq.; L. Tatham, Esq.; A. G. Duff, Esq.; W. L. Macnaughten, Esq.; Mrs. Sidney Whatson. Among the important public buildings, etc., the firm have in hand the whole of the generating plant for the Prudential Assurance Company, comprising two sets of 250 h.p. each, one set of 75 h.p., one set of 50 h.p.; also the Stafford Technical Schools, 1,100 lights: Balliol College, 370 lights; Convalescent Home, Littlehampton, 230 lights; Stafford County Infirmary, 230 lights; Cancer Hospital, 320 lights; Lancaster Infirmary, 240 lights; St. Paul's, Deptford, 110 lights; St. Michael's Church, Chester-square, 200 lights; Manchester Corporation gas-stove showrooms; University Galleries, additional arcs and incandescents; Council of Foreign Bondholders; South-Eastern Railway Company's Offices, Tunbridge Wells; North-Eastern Railway Company's Offices; Messrs. S. Allsopp and Son's Offices, etc. The factory of the Jandus Arc Lamp and Electric Company has been organised, and special machinery made for turning out every separate part, so that the Jandus arc lamp is now being put on the market upon a thoroughly commercial basis. These lamps burn from 120 to 200 hours, according to the current for which they are constructed. The "D.P. battery" business during the year has been turned into a private company, the directors being Mr. Claude Johnson (of Messrs. Johnson and Phillips), Mr. Bernard M. Drake, and Mr. Gorham. The sale of the earthing device has considerably increased, and 3,500 of these are now in daily use. No single case is known to have occurred of the apparatus having failed to effect its purpose.

THE ELECTRICAL COMPANY say: "In the arc lamp department the firm has been exceptionally busy this season, and some very large contracts have been secured for their famous 'Luna' arc lamps, including a good number from her Majesty's Government. A new self-focussing type of lamp has recently been added, which, owing to its high quality and exceedingly low price, well merits the reception it has already received. Whether for direct or alternating current, the length of the lamp's overall is very short. It is differentially wound, and supplied at a price at which shunt lamps are usually figured. Very effective ornamental lanterns of polished copper or brass, relieved with nickelled or steel bronzed parts, can be supplied for these lamps. The company claims to keep the most extensive stock of any single firm in England, both in arc lamps of all kinds and in their well-known accessories, such as resistances, choking coils, reducing transformers, winches, etc. The 'E.C.' incandescent lamp has again maintained its prestige throughout the season, and some very important contracts have been secured, including those of the large steamship companies and central stations. A new bayonet socket has been most successfully introduced, in which the insulation is maintained under any conditions. The leading-in wires do not touch the cement, which, by the way, consists of a new material, possessing exceptional tenacity. The brass contact plates are cast in with the vitrite end plate, and have ventilation holes specially provided, allowing the air to pass freely, and thereby keeping the interior dry. The E.C. lampholder, with key, is claimed to have been the first one having a combination of pistons with so-called 'A' terminals with the now universally adopted spring contact switch, and a very large trade has been the result since its introduction. It is now announced that a new holder will shortly be introduced with a new kind of patented spring contact, having all the advantages of the old type of holder with some additions. The well-known Royal switches are specified in many of the most important installations. This type of switch is particularly adapted for a variety of purposes, such as staircase-lighting, electroliers, corridor-lighting, etc. Among the measuring apparatus, the well-known 'Ready' testing sets are commanding an ever-increasing sale. The 'Dolivo' ammeters and voltmeters have maintained the high esteem in which they have stood now for quite a number of years. A new high-tension electrostatic voltmeter will shortly be added to the long list of this class of instruments. A new department has this season been added for electrical heating and cooking apparatus, and to judge by the most gratifying results already obtained, these appliances have by their own merits established a high rank for themselves, and bid fair to become most formidable rivals to their somewhat longer established competitors. The firm are now on the point of issuing a full and complete catalogue of all their goods and specialities in book form, which will shortly be distributed to the trade."

JOHNSON AND PHILLIPS write: "During the past year all the departments of this firm have been uniformly busy. The manufacture of alternators, dynamos, transformers, and central-station accessories has surpassed that of previous years. The

Digitized by Google

firm have been very busy on several large contracts, which include transmission of power plants for South Africa, alternators for the St. Helens Corporation, and the station plant for the Cape Town Electric Lighting Company. Orders for transformers continue to pour in, and the firm have more transformers of their manufacture on circuit in this country than any other manufacturers. Several of 100-kilowatts are now being constructed, and the sizes on order vary from this to half a kilowatt. The cable machinery department has been very busy on stranding, cable-making, and wire-covering machines, both for this country and abroad, and have also had in hand the picking-up and paying-out machinery, accessories, and stores forming the complete equipment for the Japanese Government's cable steamer. The arc lamp department has been kept exceptionally full of orders, especially during the latter part of the year, and nearly all the corporation contracts of the year have been secured—viz., those for Portsmouth, Brighton, Taunton, South Shields, and Edinburgh; also for the lighting of Johannesburg. The total orders are much in excess of the previous year. The new type of Brockie-Pell lamp introduced at the beginning of last year is rapidly gaining favour, and the pattern is the best yet devised. The firm are now putting down special tools for still quicker production. An exceedingly large business has also been done in carbons. The cable department has been chiefly occupied during the year with the manufacture of vulcanised rubber cables for wiring purposes and underground use. High-tension concentric mains have been completed in connection with the lighting of London, Walsall, and Malta, as well as a large quantity of single mains for various towns at home and abroad. The Brooks oil-insulated cables have been supplied for the wiring of the Glasgow Harbour tunnels, the wires being insulated with oil right up to the incandescent lampholder. It is interesting to note that the use of this system for this class of work has been a great success, and the firm looks forward to see during the present year a number of mines, tunnels, and underground railway stations lighted on this principle. In the meter department every effort has been necessary to meet the steadily-increasing demand, and standard designs for all sizes from 5 to 1,000 amperes have been prepared, in addition to those in use at the beginning of the year. From these designs instruments of all sizes have been stocked and sold, and the orders continually repeated testify to the satisfaction they are giving. Very extensive additions to the instrument shops have been made for rapidly and accurately testing these instruments. The plant put down early in the year has been kept fully occupied, and should the sales continue to increase at the same rate, as the firm has every reason to believe they will, further additions will very shortly be needed. On the whole the firm have only to congratulate themselves on the work they have secured and executed during the year, and the outlook for 1896 is regarded as extremely hopeful."

MR. LUNDBERG writes: "Business has kept well up to the usual standard, and a great improvement on that done during 1894. My various specialities continue to go well—*e.g.*, the 'Unique' switch has nearly reached a sale of 90,000 from my works alone, and is being made and sold by my licensees on the Continent. Several novelties are in hand, and I hope will be on the market shortly. Continental competition has been successfully met, and some satisfaction is obtained by sending fair quantities of goods to Germany and other important Continental countries. Business with the Colonies and other countries abroad has considerably increased, particularly Australasia, South Africa, India, and South America, and my prospects for 1896 in this direction are very satisfactory."

WALSALL ELECTRICAL COMPANY say: "During the last 12 months we have been extremely busy in all our departments. The output of our arc lamps, instruments, switchboards, motors, etc., has greatly exceeded that of any other year. The workshops have been running from early morning until late at night in order to execute customers' orders, and we have found it necessary to increase our plant and machinery to cope with the demand. We have also made improvements in our various manufactures, keeping well in touch with everything that is up to date. We have completed a number of large and important lighting installation contracts, both for private houses and public buildings. A great many of the plants for the private houses have included engines, dynamos, and storage. We have just commenced a contract within the neighbourhood of Birmingham of about 500 lamps, which includes engines, dynamo, and switchboard. We have also just finished a contract for about 250 lamps with dynamo, storage, switchboards, and have also completed the lighting-up of a large brewery with about 350 lights, including steam-engines, dynamos, motors, storage, etc., and are now finishing a contract of about 1,000 lamps, upwards of 20 motors, and about 50 arcs. Things look very bright for 1896, and we think there is every prospect of a good trade, and we have still in hand sufficient work to carry us on for some time.

HALIFAX.—Mr. T. P. Wilmshurst, the borough electrical engineer, writes: "So far as the Halifax Corporation works are concerned we have had a very successful year, and our prospects for the future are exceedingly bright. During our first 12 months' work we have connected exactly 10,000 8-c.p. lamps, and the demand is increasing. A 600-h.p. extension is now nearly completed. The financial results will be published in due course, therefore I will not dwell on them here. One of the most significant signs of the times is the concurrence of opinion that, for alternating stations at any rate, a 300-kilowatt set is not too large, and I anticipate seeing a large number of these sets at work in the near future. In the smaller alternating stations, I believe, consideration may well be bestowed on the use of a small motor-alternator set run from accumulators for the day load. I anticipate in many towns the addition of tramway generating plant to the existing electric lighting works, and in this direction is to be found the solution of the day-load problem. This question is under the consideration of my Corporation, as of many others, at the present time. Another question which deserves serious attention is the utilisation of town refuse. It appears to me this can only be relied on to supplement and not to replace a battery of coal-fired boilers and to manage the day load. Unfortunately there appears to be the difficulty that the thermal value of the refuse is least in winter, when the greatest amount of steam is required. Any well-considered scheme must, in my opinion, include a system of thermal storage. I think I echo the sentiments of many station engineers when I say that until we have before us the unbiassed statement of the actual economy gained by a large station worked in this way we shall be somewhat suspicious of the thermal value of a fuel a percentage of which consists of dead cats and tin cans. It is not solely a question of possible saving to the electricity departments, but rather of

Digitized by Google

municipal economy generally. In other words, there may be a slight reduction of expenditure at the electricity works by using refuse, but at an increased cost to the sanitary department owing to longer cartage, involving a net loss to the town. The schemes, however, which are now under weigh will be followed with much interest."

LONDONDERRY.—The Londonderry Corporation electricity works started on May 29, 1894. The loans sanctioned amounted to £18,942, and the full amount was borrowed at 3½ per cent. The half circuits are extinguished at midnight during the winter months, and are relighted again from 5.30 a.m. till daylight. The financial year of the Corporation ends October 31, and the accounts are for running from May 29 to October 31, 1894, and from November 1 to October 31, 1894-5 :

	1894.		1894-5.

Companies' Audits.—Mr. Sydney F. Morse writes on this subject :

"The correspondence between the Institute of Chartered Accountants and the Board of Trade with reference to the audit of electric light companies' accounts opens up several very interesting questions. It is perhaps not generally known that there is no enactment in the Companies' Acts requiring an audit of a limited company's accounts, except in the case of a banking company registered after August 15, 1879, as a limited company. It is true that the specimen form of articles given in Table A of the Companies' Act of 1862 provides for an audit, and that it is most unusual for any company to dispense with provisions in its articles requiring an audit, but an audit is not made obligatory by Act of Parliament.

"By Section 9 of the Electric Lighting Act of 1882 it is provided as follows : '9. The undertakers shall on or before the 25th day of March in every year fill up an annual statement of accounts of the undertaking made up to the 31st day of December then next preceding, and such statement shall be in such form and shall contain such particulars and shall be published in such manner as may from time to time be subscribed in that behalf by the Board of Trade,' and the model form of provisional order provides as follows : '8. The annual statement of accounts of the undertaking before being published as provided by Section 9 of the Electric Lighting Act, 1882, shall, so long as the local authority are not the undertakers, be examined and audited by such competent and impartial person as the Board of Trade shall appoint ; and the remuneration of the auditor shall be such as the Board of Trade shall direct, and the same and all expenses incurred by him in or about the execution of his duties to such an amount as the Board of Trade shall approve shall be paid by the undertakers on demand, and shall be recoverable summarily as a civil debt. The undertakers shall give to the auditor, his clerks and assistants, access to such of the books and documents relating to the undertaking as shall be necessary for the purposes of the audit, and shall, when required, furnish to him and them all vouchers and information requisite for such purpose, and shall afford to him and them all facilities for the proper execution of his and their duty. The Board of Trade may make and vary regulations prescribing the times at and the mode in which such audit shall be made and conducted, or otherwise, for the purpose of giving effect to the provisions of this section. Any report made by the auditor, or such portion thereof as the Board of Trade shall direct, shall be appended to the annual statement of accounts, and shall form part thereof for the purposes of the said Section 9.'

"There is no clause similar to Section 9 of the Act of 1882 in the Gasworks Clauses Act, or in the Railway Clauses Act, and the Companies' Clauses Act of 1845 merely provides for the election of auditors by the company, except where by the special Act auditors shall be directed to be appointed otherwise, and these auditors are directed to examine the accounts, and either to make a special report on the accounts, or simply to confirm the same, such report or confirmation to be read with the report of the directors at the ordinary meeting.

"On the other hand, the Metropolis Water Act of 1871 provides that every company for the time being supplying water for domestic use within the limits of the Act is to forward to the Board of Trade and certain other authorities a statement of account in such form and giving such particulars as may from time to time be prescribed by the Board of Trade, and there is to be an auditor from time to time appointed by the Board of Trade.

"Section 40 of this Act provides as follows: '40. The auditor shall once in every half-year audit the accounts of the companies. If he finds the accounts correct he shall certify the same, but if in any instance he finds the accounts of any company incorrect in principle or in detail, he shall require such company to correct such accounts in such manner as he thinks right, and no future dividend shall in any case be declared by any company until their accounts are certified by the auditor, provided that the suspension of a dividend under this section shall not operate until after the expiration of nine months from the date of the audit.'

"But any company thinking themselves aggrieved by any act or determination of the auditor can, under Section 42, bring the matter to arbitration.

"Now, it will be noticed that there is a great deal of difference between the provision for the annual statement of accounts to be made to the Board of Trade under the Electric Lighting Act, even when coupled with the audit clauses of the provisional order, and the provisions of the Metropolis Water Act of 1871, under which power is given to the auditor to require a company to correct any accounts which he finds incorrect in principle or in detail. And I submit that the auditing of an electric lighting company's accounts by the Board of Trade is merely made for the purpose of obtaining independently statements as to the expenditure, and as to the application of revenue with a view to the special provisions of the Act and provisional order, and particularly with a view to the anticipated purchase by the local authority at the expiration of the statutory period, and that the Board of Trade auditor has no power to direct such a company to alter its accounts in principle or in detail unless he can show that the company has committed a breach of the terms of the Electric Lighting Acts or provisional order.

"The letter from the Board of Trade recently published states (as I claim in support of this suggestion) 'that the Board of Trade audit is of a different character to that of a shareholders' audit, and has in view different objects.' Moreover, there is no audit clause in the model provisional order, the 'undertakers being a local authority.'

"Now, the object for which the shareholders' audit is made is that as between the directors and the shareholders it shall be shown that capital is not paid away in dividends, that all payments are duly vouched and all receipts duly entered, and proper provision made for bad debts or contingent liabilities, and, in fact, that the accounts are properly kept, having regard to the constitution of the company.

"If the above suggestions are correct, the importance will at once be seen of drawing the line between the two audits and limiting the rights of each auditor to interfere in the management of the accounts to the special provisions under which his appointment is made.

"If this is not done, each auditor may by degrees get into the way of directing not only how the accounts shall be kept, but also what amounts are properly chargeable to capital and revenue respectively, and if they do not take the same view very serious difficulties may arise ; whereas if, as I submit, the duties of the Board of Trade auditor are limited to ascertaining and seeing that the provisions of the Acts and order are duly carried out, while the shareholders' audit deals with matters arising out of the special constitution of each company and the proper keeping of the accounts, there need be no difficulty.

"But I do submit that there is this distinction, and that it should be carefully observed."

The following is a complete list of applications for provisional orders deposited with the Board of Trade up to December 21, 1895, under the provisions of the Electric Lighting Acts, 1882 to 1890 :

(Continued from page 737, Vol. XVI.)

DEPENDENCE OF DISTRIBUTION ON SHAPE OF CRATER AND PEAK.

During the minutes which have elapsed our arc has been steadily burning and the crater on the upper carbon has assumed the oblique position. The peak remains as a peak and is visible against the crater surface, which it partially hides from our view. The main amount of light (see Fig. 10) is now given off in a not quite horizontal direction.

To make experiments on the amount of light given out in different directions one requires either a photometer capable of being shifted round into all possible angular positions or some apparatus for turning the arc into different inclinations with respect to the photometer. There is, however, an intermediate possibility—namely, some method of optically tilting the lamp so that its light shall still come to the photometer, no matter what the inclination may be. To enable you to see upon the screen what the arc looks like when viewed at different inclinations, the following apparatus has been devised (Fig. 13).

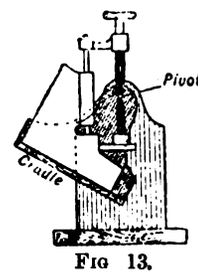

FIG 13.

Here is a small projector lamp (made by the Planet Company) for the purpose of magic-lantern work. This little lamp is fixed on a cradle-shaped stand so that it can be rocked about on horizontal trunnions, the line of axis of these trunnions passing right through the arc. When the arc is burning steadily, while we project its image upon the screen by means of a lens placed in front, we can tilt it to any angle desired and set it either vertically or with any desired inclination towards the horizontal plane. So here we accomplish the same result as viewing the arc obliquely from positions below.

* Cantor lectures delivered before the Society of Arts.

Digitized by Google

If I set the cradle so as to bring the rim of the crater into the horizontal plane with the carbons vertical I shall have the arc in the position of habitual use (Fig. 1), and on the screen you see the sideway view. You see that very obvious peak and above it the edge of the white-hot crater. If I lengthen the arc a little you will see the peak burn away to a blunter form, while the crater will become flatter. Having now seen the form sideways, I will tilt back the cradle so that we may get another view of it. The duller spot which you see in the middle of the crater arises from the circumstance that we are employing a cored carbon—that is to say, a carbon with a hole down the middle—packed with carbon of a more or less soft quality and possibly not quite pure. As the cradle is tilted, the negative peak comes in front of the crater and shows dark against its luminous surface. Turning it to a still steeper angle so as to get in a horizontal direction the equivalent of the light which would otherwise be thrown obliquely downwards, we find the negative peak almost eclipsing the crater and cutting off its light.

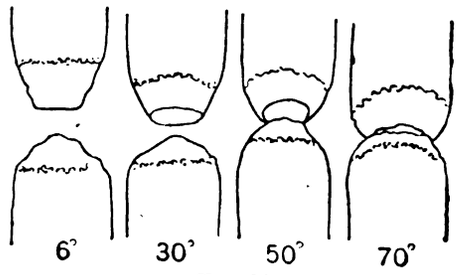

FIG. 14.

Fig. 14 shows four views at four different angles 0deg., 30deg., 50deg., and 70deg. In the two extreme positions, where the crater is seen only edgeways, and where it is eclipsed by the peak, there is very little light; but at some angle between these two there will obviously be a position where the light is a maximum. The crater, at first seen edgeways, seems to open out into an ellipse, which widens until the intruding peak eclipses it. There will obviously be a maximum position between the two minima. For a long time this was not very well explained. M. Rousseau, who made some observations by means of a polar photometer on the arc lamps shown at the exhibition at Antwerp in 1885, tried to express the results by using some long and complicated formulæ.

TROTTER'S THEORY OF DISTRIBUTION.

In the spring of 1892, Mr. Alexander P. Trotter, who has done so much in arc lamp optics and physics, showed a much simpler way of treating the matter. He started from the physical standpoint at which I explained in my first lecture I arrived in 1889—viz., that because the arc is a phenomenon due to the volatilisation of carbon, it will have a definite temperature, and, therefore, assuming that temperature to be definite and the carbon to be pure, the light emitted at the crater surface will have a definite whiteness. Starting from that point he argued as follows: It does not matter for optical purposes whether the crater is actually flat, or whether it is literally of a cup shape, since a luminous surface gives out only as much light in any direction as would be given out by a flat surface of equal intrinsic luminosity having exactly the same outline. This may seem a little strange, because it is contrary to one's experience of surfaces that are not self-illuminating. Take, for instance, an ordinary white saucer illuminated by the sky or by artificial light. If you set that saucer up in any one particular position, and enquire how much light it throws to your eye as you move round it in different directions, you will find as matter of measurement that the amount of light given out in different directions does not depend simply on the visible size of that saucer, but owing to the circumstance that it receives its light at a particular angle and reflects it; the amount of light given out to your eye by any visible area of its surface depends upon the angle at which you see it. But where you are dealing with a self-luminous surface this is no longer true. For instance, take a piece of white paper as a sort of model; imagine it to be a white-hot surface. Look at it through any definite aperture—for instance, through this tube. You will see a round luminous disc (of a certain size, limited by the aperture). It will not make 1 per cent difference whether the white surface behind it is absolutely square across or whether it is turned or tilted obliquely. As long as there is enough white surface behind to extend completely across the visible aperture, the aperture will look equally bright. The angle of incidence to the sloping surface behind the aperture has nothing to do with the brightness. The self-luminous surface is equally bright whether it slopes or whether it stands squarely opposite to the eye. The crater surface may, therefore, for optical purposes, be considered to act as a small white-hot horizontal disc.

The amount of light that it will emit in any given direction will depend simply, in the first place, on the intrinsic brightness, and, secondly, on the visible area which it presents when viewed in that direction. The more obliquely it is viewed the less is the visible area. The amount of light ought to be strictly proportional to the apparent area as viewed in the direction in question. Mr. Trotter's first point, then, is that the crater, no matter what the actual hollow may be, may be treated as a flat disc suspended somehow or other up in the air, and shining white hot. Then what will be the geometrical distribution of light in all directions from this disc? That will be simply a matter of angle, or, rather, of the cosine of the angle. The disc will appear biggest, at any given distance away, if the eye is placed exactly opposite it. Because when the disc is square across the line of sight, it obviously will subtend the greatest apparent angle in space. It will appear of no size at all in directions at right angles to this, because the disc is edgeways, and the edge has no visible magnitude quantity. There will be no light in that direction; in other directions there will be some light. There will be a maximum in the direction of the normal to the surface; and the amount in any other direction will be simply proportional to the cosine of the angle which that direction makes with the normal. If you take the cosine of the angle as measured from the normal, or the sine of the angle as measured from the horizontal plane, and plot out the values in a polar diagram, as in Fig. 16 below, you will find the points all lie on a semicircle. In brief, cosines plotted as a polar curve give geometrically a circle that passes through the pole. Therefore, if this law were to be literally fulfilled, and if our crater were a horizontal disc up in the air—whether circular in outline or not is immaterial the amount of light measured in different directions, provided there were nothing to interfere, would plot out simply on a semicircle, giving us the diameter of the semicircle as the greatest amount of light measured down underneath the disc. Unfortunately, the arc lamp consists of something more than a top carbon with a level crater at the end of it. There is that unavoidable negative peak which gives out very little light of its own, which is merely being roasted in the heat of the crater above it, and which casts a shadow. If you will measure the amount of the eclipse that goes on in different directions, you will get a measure of the amount of light cut off in those directions from the amount that would be strictly proportional to the cosine of the angle. No sooner had Mr. Trotter conceived this idea than he was good enough to come and talk it over with me at the Technical College. I put one of my senior students, Mr. C. F. Higgins, at his disposal to devise a little piece of apparatus to test this theory. Mr. Higgins constructed the apparatus used by Mr. Trotter in the investigations which followed. I have the apparatus here (Fig. 15)

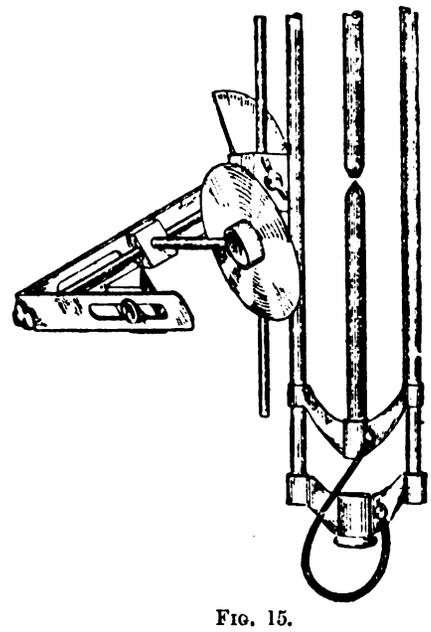

FIG. 15.

fixed on one of the Planet Company's lamps. There is attached to the framework of the lamp the small apparatus by means of which the light given out from the arc in any direction can be examined. A lens is placed opposite the arc at a certain distance away; the light from that lens is received on a small mirror, having its front face metallised. The mirror being set at 45deg., sends out the light at right angles, to a distant screen, where the image is received. Then by merely tilting to any desired angle the frame which carries lens and mirror, one can examine, in any direction within wide limits, the visible appearance as presented in that direction. Armed with this instrument, one can make photometric measurements of the light sent out at different angles without moving either lamp or photometer. But of more importance is the fact that by focussing the images on the screen one can make pictures of the visible forms of the carbons. Putting a sheet of white paper against the screen you project on it any particular view of the

Digitized by Google

arc you like, and then with a drawing-pencil outline the projection on the paper. Having in this way obtained a series of sketches of the arc as projected at various known angles (and all on the same scale), you may then go over each sketch with a planimeter and measure up the amount of luminous surface that is visible in different directions.

This elegant method of determining the illuminating effect at different angles is a feature of Mr. Trotter's investigation. In his paper in the *Journal* of the Institution of Electrical Engineers Mr. Trotter gives his results plotted out in the form of curves. In one curve he plotted the intensity of the light as measured in different directions. In another curve he plotted the amount of visible crater area as measured in the different directions. So close is the agreement that the curves are scarcely to be discriminated one from the other. Fig. 16 gives

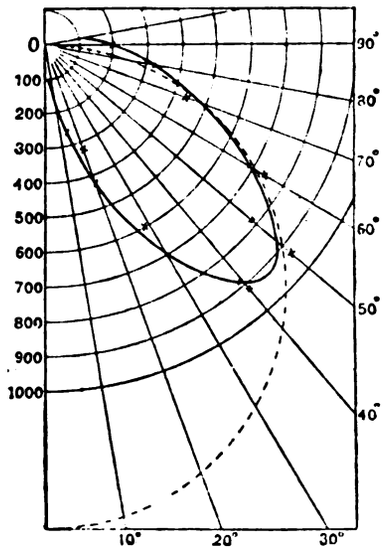

FIG. 16.

the curve of visible areas plotted as a polar diagram. The dotted semicircle gives the values of the cosines, which are proportional to the area of crater surface which would be visible if it behaved exactly as a disc, and had no obstruction in front. The light in any given direction is apparently proportioned to the amount of visible crater area exposed in that direction. This is a very important result, because it enables us to see exactly why the light is distributed as it is. Before Mr. Trotter's experiments there had, however, been some other observations made, dealing with the relation between the amount of light and the amount of current.

INTRINSIC LUMINOSITY OF THE CRATER.

Let us proceed to correlate Mr. Trotter's observations on the relation between the amount of light and the crater surface with those earlier observations on the relation between the crater surface and the current.

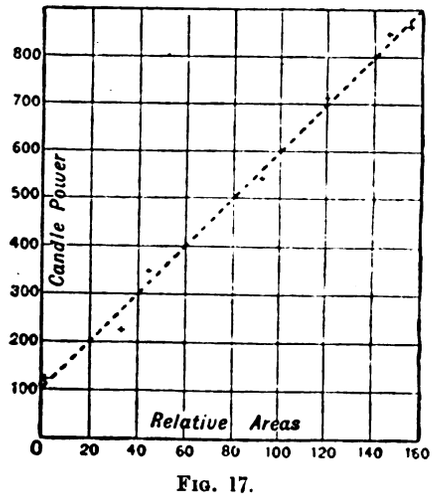

FIG. 17.

We will take, first of all, Mr. Trotter's results, in which we compare together the amount of light, as measured photometrically, and the amount of crater area, as determined by projecting the images on the screen, and measuring them with a planimeter. Fig. 17 gives in graphic form the result of Mr. Trotter's researches on the relation between the candle-power of the arc and the visible area of the crater surface. The candle-power is plotted out vertically, and the corresponding areas of crater surface are plotted out horizontally; they lie practically on a straight line. The main thing substantiated is that, taking a certain datum line horizontally across the diagram at about 100 candles, any amount of light above that datum line is exactly proportional to the amount of area of crater surface. Then what is the meaning of having this datum line above the actual zero of candle-power? It means this, that all the light below that line drawn at about 100 candles was due to other parts than the crater. That is to say, the total amount of light given out by the negative peak by the duller red-hot regions around the peak, and around the rim of the crater and by the flame of the arc, amounted to about 100 candles. If we then discount this extra light which strays in from the other parts, we may say that the light given out is strictly proportional to the area of the crater surface. The other result I wished to correlate with this was an observation of Mr. J. D. F. Andrews's on the relation between the crater area and the current going through the lamp. This research dates from 1880, before we began to talk about amperes of current, and when we talked about webers. Andrews's researches were on the number of webers of current going through a searchlight, and the amount of crater area as measured in the following way: After the lamp has been allowed to burn steadily for a given time, the current was stopped, and the carbons taken out. The size of the crater was measured up, and from that the area of crater surface was calculated. The observations plotted together, as in Fig. 18, give a straight line which goes right down to zero. The current in these experiments was found to be rigidly proportional to the actual area of the crater. Consequently it follows, from Mr. Trotter's results, that the amount of light given out by a lamp (in any given direction) is also proportional to the current passing through that lamp.

If, then, the light emitted is simply proportional to the effective crater area, it ought to be possible to set down in definite terms the specific luminosity of the arc crater as so many units of light per unit of area. Many years ago, Mr. Hiram Maxim had arrived, I know not by what process, at a similar conclusion. He gave the rough-and-ready rule that you can calculate the total candle-power of a lamp by measuring the diameter of the crater in hundredths of an inch, squaring the number, and then multiplying by 10. This is equivalent to 127,000 candles per square inch, or approximately 200 candles per square millimetre—a figure which is high compared with those of other observers. Abney's values range from 39 to 116; Andrews's

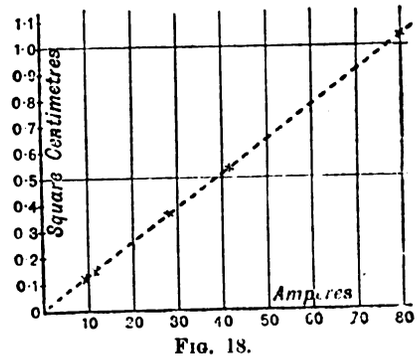

FIG. 18.

from 64 to 170; Trotter's, from 80 to 170; while Blondel's value is 160. The number of amperes per square millimetre of crater surface is about 0·78; so that the number of candles per ampere should be over 200. Palaz gives 204 to 240 in the direction of maximum brightness.

It will not, however, do to jump to the conclusion that because the crater area, and, therefore, the total quantity of light emitted, is proportional to current, that doubling the current in any given arc lamp will exactly double the light that that lamp gives out. For, if the current used at first is appropriate for the carbons of the size employed, a double current will be much too great to produce a proper crater, and the pencils will overheat. Moreover, the distance between the tips and the form of the tips will differ, and the distribution of the light will be different, preventing a fair comparison. Palaz gives the empirical rule that for a given lamp and carbons working between 40 and 50 volts, the number of candles (*bougies decimales*), if measured in the direction of maximum brightness, is equal to $200\,C + 4\,C^2$, where C is the current expressed in amperes. According to this, a 10-ampere current would give 2,400 candles in the maximum direction, while one ampere would only give 204. (The mean hemispherical brightness is only about two-thirds of the maximum.)

[*Note added, October*, 1895.—Shortly after the delivery of this lecture, Mrs. Ayrton published in the *Electrician* the results of her measurements of the crater, from which it appears that the current is not exactly proportional to the area of the crater, nor yet to its diameter, but to some power of the diameter between 1 and 2. On examining the curves on which her formula is based, it seems evident that further experiments are needed before the approximate law that the area of the crater is proportional to the current can be condemned.—S. P. T.]

* Retested (see report for 1894).

The resistance coils referred to in the last report as defective in insulation have been refilled, and up to the present their insulation has proved satisfactory.

The set of standards ordered from Germany has not yet arrived. When they are received a careful comparison will be made between their values and those of the standards of the association.

During the year the committee have had under discussion a paper on magnetic units prepared by Dr. Lodge and printed as an appendix to this report.

The committee recommend that they be reappointed; that Prof. G. Carey Foster be chairman, and Mr. R. T. Glazebrook secretary.

APPENDIX.

MAGNETIC UNITS.

To the British Association Committee on Electrical Standards:

Believing that the committee is impressed with the convenience of affixing names to some of the more important units connected with the magnetic circuit I beg to suggest the following considerations and recommendations, which I will write out as briefly as possible. The statements are intended to be precise in their terms, but in several cases alternative forms of definition are given

(1) That the unit coefficient of self induction, though frequently useful, is by no means one of the most fundamental units, but should be defined in a suitably subordinate manner with reference to other and more important quantities.

(2) That it would be a mistake so to define it as to discourage the employment of the same term for as many other quantities of the same "dimensions" as possible; especially for the unit coefficient of mutual induction, and for unit "permeance."

(3) That the essentially different quantities commonly called H and B should be carefully kept distinct, although their measures in air have been conventionally so arranged as to be numerically equal.

(*Summary of Known Facts and Definitions*).—H being the intensity of magnetic force at a point, or the slope of magnetic potential, ω,

$$\omega_a - \omega_b = \int_a^b H\,ds, \text{ along any portion, } a\,b, \text{ of a line of force;}$$

and in a closed magnetic circuit the circuitation of H is equal to 4π times the total electric current through the area bounded by the magnetic circuit; or,

$$\text{cycle } \int H\,ds = \text{circuitation of } H = \iint 4\pi c\,dS = 4\pi C.$$

or, at any point of space, $\text{curl } H = V\nabla H = 4\pi c$; where c is current density.

If the electric circuit consists of n turns of wire threading the magnetic circuit, and each conveying the current C_1, then $C = n C_1$

First Quantity to be Named.

(4) The first thing requiring a name is this quantity *magnetic potential*, sometimes called *magneto-motive force*; a quantity spoken of and measured, not inconveniently but with insufficient generality, by electrical engineers as ampere-turns. It has been proposed (by Mr. Heaviside for instance) that it be called *gaussage*, and that its C.G.S. unit be one *gauss*.

(5) The circuital gaussage round a closed curve is 4π times the total electric current through the area bounded by that curve. In the case of a magnetic circuit wound with wire the gaussage is $1\frac{1}{4}$ times ($\frac{4\pi}{10}$ or 1·2566) the ampere-turns threading that circuit.

Note.—It *may* be best to retain the word "gaussage" for the whole of a closed circuit only, and to speak of the difference of magnetic potential between two points as the fall of gausses or the "gauss-fall" from a to b.

(6) The gaussage, or gauss-fall, in any portion $a\,b$, of a magnetic circuit is measured by the change in the potential energy of a unit pole as it moves from a to b by any path which involves neither the cutting of magnetic layers nor the encircling of currents (a long channel being imagined for its motion through solid material if necessary). Or, more practically, it is measured by the induction through a long narrow tube whose ends are at a and b respectively, divided by the permeance of that tube. (*Cf.* Chattock on a magnetic potentiometer, *Phil. Mag.* July, 1887.) In practice, however, gaussage is frequently calculable from the ampere-turns to which it is due.

(7) Intensity of magnetic force, or H will be naturally expressed as gauss-fall per centimetre, or the *gauss-gradient*. For instance, the earth's horizontal intensity at some place is ·18 gauss per linear centimetre, or 5·4 gausses per foot.

Note.—It should not, strictly speaking, be expressed as so many lines per square centimetre; that mode of expression should be reserved for induction density, B. H is the cause, and should be thought of as the slope of magnetic potential, B is the effect. In a medium of so-called unit permeability the two quantities are numerically equal, but they should not be confounded, any more than the slope of electric potential, or electric intensity (e) should be thought of as identical with current density, even in a medium of unit conductivity.

(8) The gauss gradient inside a long or closed magnetic solenoid of length l, wound uniformly with n turns of wire each conveying the current C_1, is $4\pi n C_1/l = 4\pi n_1 C_1$; where n_1 is the total number of turns of wire (in all the layers) to the linear centimetre. This is the measure of H in the interior of such a solenoid, quite irrespective of the material with which it may happen to be filled.

Second Quantity to be Named.

(9) The second quantity requiring a name is the *total induction* in a magnetic circuit, also called "total flux," "total lines," "electromagnetic," and "electrotonic state." It is the quantity whose time-rate of variation gives the voltage induced in an electric circuit surrounding it once. It is proposed that its practical unit be called a "weber," and be defined as equal to 10^8 C.G.S. lines (or unit tubes) of induction. (Denote the quantity for the present by N, and its density by B.)

Summary of Known Facts.—e being the intensity electric force, or the slope of electric potential, or the volt-gradient a point; the circuitation of e = the induced E.M.F. in a closed circuit = the rate of change of induction through it;

$$\text{or, } \text{cycle } \int e\,ds = E = -\dot{N} = -\iint \dot{B}\,dS;$$

or, at any point of space,

$$\dot{B} = -\text{curl } e = -V\nabla e.$$

Through a simple closed electric circuit of constant resistance,

$$N = -\int E\,dt = \int R C\,dt = R Q.$$

(10) The total induction through any area may be practically measured by suddenly surrounding it with a closed-wire circuit of n turns connecting the terminals of a ballistic galvanometer, and measuring the quantity of electricity thereby impelled through the galvanometer. The induction is equal to the quantity so impelled divided by n times the resistance of the circuit. If the quantity is one coulomb, and the resistance one ohm, the induction is $1/n$th of a weber. Or, otherwise, if the induction through any boundary changes at the rate of one weber per second, the E.M.F. excited in that boundary is one volt. In the case of a wire circuit through which induction is varying at the rate of a weber per second, one volt is excited *in each turn* of the wire.

(11) *Another* mode of measuring the total induction through an area is to surround that area with a movable electric circuit of n turns of wire conveying a known current, and to measure the potential (or mechanical) energy of the circuit under those conditions. The induction is equal to the potential energy of the circuit divided by n times the current circulating in each turn of wire. Or, if the induction through a simple circuit carrying one ampere is one weber, the potential energy of the circuit is one joule.

Derived Quantities.

(12) Induction density, or B, may be expressed as so many webers per unit area; say, per square centimetre or per square inch, or whatever is preferred for practical purposes. For instance, the earth's horizontal induction density at some place is ·18 C.G.S.

Digitized by Google

unit = $\cdot 18 \times 10^8$ weber per square centimetre = 18 microwebers per square metre.

(13) The inductivity, μ or absolute permeability of a medium at any point under specified circumstances, is the ratio of B to H at that point, and under those circumstances. In many substances this ratio is far from constant. [It may be expressed in terms of henries or other units of permeance per unit length (see below), instead of C.G.S. units, if convenient. For example the inductivity of air is $\frac{1}{1000}$th of a microhenry per centimetre, or one millihenry per kilometre.] More explicitly it is measured by the webers per unit area divided by the gauss fall per unit length; in other words, by the ratio of the weber density to the gauss gradient.

(14) The relative inductivity of a substance is compared with that of empty space (μ/μ_0) may be called simply its "permeability" as at present and is a mere number. (Its electrical analogue is specific inductive caacpity (K/K_0), as contrasted with absolute electric inductivity (K); which latter could be defined in practical units as the ratio of the coulombs displaced per unit area to the volt gradient.)

Third Quantity to be Named.

The third quantity for whose unit a name is required is some form of ratio between the two fundamental quantities whose units are here named after Weber and Gauss respectively. It has been practically decided in America that this unit shall be named after Prof. Henry, of Washington, but the precise definition has not yet been agreed upon.

There are two quantities of the same physical dimensions to which the name is applicable—viz., the coefficient of self or mutual induction of a coil or coils of wire, and the permeance or inverse reluctance of a magnetic circuit.

The most logical order is to define permeance first as the ratio of the webers of induction to the exciting gaussage, and then to say that the inductance of a coil of n turns of wire is n^2 or $4\pi n^2$ or $\cdot 4\pi n^2$ times the permeance of the magnetic circuit which it embraces, according to the units of gaussage and current which have been decided on. If the units of gaussage and current are both the C.G.S. units, then $4\pi n^2$ is the numerical factor connecting inductance with permeance. If the C.G.S. unit of gaussage is adopted along with the ampere current, then $\cdot 4\pi n^2$ is the factor. But if the circulation of H due to *one ampere turn* is adopted as the practical unit of gaussage, then n^2 is the factor, and the permeance of a cylinder, instead of being simply $\frac{\mu A}{l}$, is $\frac{4\pi\mu A}{10 l}$.

The apparent simplicity of this last system has much to recommend it for commercial use, though it will complicate the specification not only of permeance but also of magnetic fields and potentials; but *some* inconvenience due to the unfortunate definition of the unit pole, and the only less unfortunate definition of the practical unit of current, cannot be avoided; but our aim must be to place the inconvenience where least likely to be felt in everyday work.

First System.

We will begin with the more logical system, and with general statements which apply to both.

(15) In a complete magnetic circuit the ratio of the total induction to the corresponding gaussage under specified conditions is called the "permeance" of that circuit under those conditions. It is not, in general, constant. Or, the permeance of any solenoidal portion of a magnetic circuit, if free from intrinsic magneto-motive force or magnetic boundary layers, is the webers through it divided by the gausses between its ends.

(16) The practical unit of permeance is that of a circuit in which a weber is excited by a gauss. Its reciprocal is the unit of reluctance. The practical unit so defined is 10^8 C.G.S. units.

Examples.—The permeance of a cubic metre of air to parallel induction from one face to the opposite is one microweber per gauss. Under circumstances such that the permeability of iron is 400 times that of air, the permeance of an iron ring of one decimetre cross-section and one metre in mean diameter is $\frac{400\pi r^2}{2\pi R} = 20r = 100$ C.G.S. = again one microweber per gauss. It is, perhaps, a question whether this amount of permeance could be called a "microhenry" without confusion.

Explanation.—The inductance (or self-induction coefficient) of an electric circuit consisting of n turns of wire, so far as it is constant, is defined to be equal to n times the induction produced through it by a current of one ampere in each turn. But the gaussage due to n ampere-turns is $\frac{4\pi n}{10}$ or $\cdot 4\pi n$; hence the inductance of a wire coil is $\cdot 4\pi n^2$ times the webers caused by each gauss in the magnetic circuit surrounded by it—*i.e.*, $\cdot 4\pi n^2$ times the permeance of that circuit considered as constant.

(17) A coil of wire threading n times a complete magnetic circuit of unit permeance under any given circumstances is said to have $\cdot 4\pi n^2$ units of inductance under those circumstances, and, in general, the inductance of a coil of n turns is $\cdot 4\pi n^2$ times the permeance (as above defined) of the magnetic solenoid enclosed by it. (The permeance may here be considered variable.) [With the ampere-turn as unit gaussage the $\cdot 4\pi$ is prefixed similarly to both inductance and permeance, so that only the factor n^2 is needed to convert one into the other. See below.]

(18) The C.G.S. unit of inductance is equal to n times the induction excited through a coil per C.G.S. unit of current in every turn of wire, whereas the practical unit of inductance is n times the webers excited per ampere, hence the practical unit of inductance is 10^9 times the C.G.S. unit. The practical unit is called a "henry." (It has also been called secohm and quadrant.)

Example.—If the above iron ring were wound closely with 1,000 turns of wire, the coil would have a coefficient of self-induction equal to $\frac{4\pi}{10}$, or 1¼ henries whenever the permeability of the iron was 400. A coil of 20,000 turns of wire, wound closely on the same core, would have an inductance of 1¼ henries if it contained air or other non-magnetic substance.

Alternative Mode of Definition of Inductance on First System.

In view of one of the above practical methods of measuring induction experimentally, the inductance of coils of wire, both self and mutual, may be defined more directly thus:

(19) When of two simple circuits one conveys a current, the other, in general, has induction caused through it, and the ratio of the induction through either to the inducing current in the other is called the mutual inductance of the circuits.

(20) Of two coils with n and n' turns respectively, the total mutual inductance is to be reckoned for every turn of wire on each coil, and is therefore $n\,n'$ times the inductance of the mean turn of one coil on the mean turn of the other.

(21) The mutual inductance of two coils is $4\pi n\,n'$ times the permeance of the largest magnetic solenoid which threads both. For if every turn of one conveys a current C, while every turn of the other surrounds an induction, N', in consequence, the permeance of the magnetic solenoid threading the second coil is $P = N'/4\pi n\,C$; but the total effective mutual induction, M C, through all the turns is $n'\,N'$; hence $M = 4\pi n\,n'\,P$.

(22) When two coils each conveying one ampere are constantly connected by one henry of mutual inductance the kinetic energy of the field due to their mutual action is one joule.

(23) If the *self* induction coefficient of a coil is being considered, its total inductance may be taken as n^2 times the inductance of the mean turn—that is, n times the total induction through it divided by the inducing current; or the weber-turns per ampere give the self-inductance in henries.

(24) The practical unit of inductance, whether self or mutual, is called a henry; and a coil of n turns has a henry of inductance, on itself or on another of n' turns, when an ampere in one maintains $1/n'$ weber of induction (through itself or) through the other.

(25) When the induction through a coil varies for any reason at the rate of one weber per second, the E.M.F. generated in each turn is one volt.

(26) When the inductance of a coil is one henry, on itself or on another, a small variation of current in it at the rate of one ampere per second induces an E.M.F. of one volt in itself or in the other.

(27) When the inductance of a coil conveying one ampere varies at the rate of a henry per second, the induced E.M.F. is one volt.

(28) When the self-inductance of a coil is constantly, or on the average, one henry, while an ampere current is generated in it, the kinetic energy of the field due to that ampere is half a joule.

Second System.

(29) If instead of taking a gauss as equal to a C.G.S. unit of magnetic potential, we take the circulation of H caused by one ampere-turn as the practical unit of magneto-motive force, we shall have one ampere-turn $= \frac{10}{4\pi}$ C.G.S. units of gaussage.

(30) The practical unit of permeance will then be that in which a weber of total induction is excited by each ampere-turn; in other words, it will be $4\pi \times 10^7$ C.G.S. units of permeance.

(31) And the practical unit of inductance will be that of a coil in which an ampere in every turn excites $\frac{1}{n}$th of a weber through every turn—that is to say, the inductance of a coil will be n^2 times the permeance of the magnetic circuit surrounded by it.

(32) The difference between inductance and permeance is only one of reckoning. Permeance is webers per ampere-turn. Inductance is weber-turns per ampere.

SUMMARY OF THE ADVANTAGES OF THIS SORT OF MODE OF DEFINING UNIT INDUCTANCE.

The special feature of this mode of defining the "henry" is that it makes inductance depend on the simple ratio N/C, or weber-turns per ampere, instead of on something more complicated.

It might possibly be defined as the ratio $d\,N/d\,C$—that is, as proportional to the tangent of the slope of the B : H curve; and such a definition would emphasise its variability, but certain practical advantages would be lacking, because it would be detached from any connection with the *permeance* of the circuit. The N/C ratio, on the other hand, instantly connects itself with permeance, and represents the slope of the secant drawn from the origin to any point of the B : H curve. It exhibits the variability sufficiently, making the inductance reach a maximum at the shoulder of the curve, and then slowly decrease as saturation sets in.

It is sometimes said—but the mode of expression is, to say the least, very inconvenient—that there are three different principles on which to define L, all leading to a different result—viz., numbering them inversely, but giving them in their usual order:

(3) Energy ..... $W = \frac{1}{2} L C^2$;
(2) E.M.F. ..... $E = L\,d\,C/d\,t$;
(1) Total induction $N = L C$.

But the real facts to be expressed are not here exhibited. The real facts are—

(1) $N = L C$;
(2) $E = d\,N/d\,t$;
(3) $d\,W = C\,d\,N$.

The essential thing to name is therefore N; and if 10^8 C.G.S. lines or unit tubes be called a "weber," or a "weber-turn," then a volt is a weber or a weber-turn per second, and a joule is a

Digitized by Google

weber-ampere turn. Nothing can be handier than that, and a henry can be defined as a weber-turn per ampere.

Instead of saying as above, that there are three ways of defining L, the simplest thing is to say that two of the three equations as first given above are incorrect, except for the special and in practice comparatively rare case when L is constant. Written out correctly they stand as follows :

$$(1)\ N = L\,C\ ;$$

$$(2)\ E = \frac{d\,C}{d\,t} + C\,\frac{d\,L}{d\,t}\ ;$$

$$(3)\ W = \tfrac{1}{2}\,L\,C^2 + \tfrac{1}{2}\int_0^C C^2\,d\,L.$$

It is then obvious that (2) and (3) are too complicated to base a definition upon, and that the first alone gives a feasible system

The fact that L is decidedly not, in general, constant deprives the henry of any such importance as the ohm possesses ; moreover, it refers explicitly to rather a special thing—viz., a coil of wire and that under specified conditions, if it contain iron ; hence it would be rather absurd to name this alone of all magnetic units In the above communication, in addition to a certain mode of defining the henry, it is urged that unit total induction be named too ; for this is the quantity which is of real engineering importance—this is the quantity to attain which field magnets are built, and in the midst of which armatures are spun.

It is also urged that it would be convenient if unit magnetic potential could likewise be named, since electrical engineers have shown that they have need of some such unit for the exciting cause of induction, by their practical employment of the phrase "ampere-turns." The introduction of a gauss unit, in some form not too obviously limited to the case of a wire-wound coil, would assist teaching and would clarify magnetic ideas.

The present writer does not presume to decide between the two alternative systems of defining "the gauss" as given above—viz., the C.G.S unit on the one hand, and the ampere-turn on the other.

OLIVER J. LODGE.

Liverpool, December 9, 1894.

APPENDIX.

It need hardly be said that in the last resort it rests with practical men to employ or decline any suggested system of units. Those who daily deal with the quantities under consideration are the best judges of the utility or otherwise of a suggested unit, provided always that they take the trouble to give it a fair trial and see how it works in practice. It may be hoped that the above or similar suggestions will meet with criticism at the hands of such men, and in order to make a beginning of criticism I asked the Departmental Lecturer on Electrotechnics at University College, Liverpool (Mr. F G. Baily), to consider them with special reference to (1) the large size of the weber and henry units ; (2) the handiest definition of the gauss ; and (3) the least troublesome mode of bring in the 4π.

His reply, which is annexed, covers these points, and also incidentally refers to the quantity called I, or intensity of magnetisation.

Now, as must often have been pointed out, the equation $B = H + 4\pi I$ is a barbarous one, involving as it does quantities of different dimensions in one equation. Its true meaning is of course $B = \mu_0 H + (\mu - \mu_0) H$; which, although algebraically only a roundabout method of writing $B = \mu H$, is yet convenient, as exhibiting separately the part of the induction due to the ether and the part due to a material medium.

The customary convention of further denoting $(\mu - \mu_0)/\mu_0$ by the symbol $4\pi\kappa$, and then christening κH as the magnetisation, I, is likewise convenient. With this definition κ is a pure number, and I is a gau-s-gradient or field intensity. Another, but on the whole less satisfactory, definition—viz , the omission of μ_0 from the denominator—would make κ of the same dimension as μ, and I an induction density.

The pull between two parallel magnetised surfaces of area A is $\frac{1}{2} A B H \div 4\pi$—that is to say, $N H/8\pi$, and is therefore measured in webers multiplied by the gauss gradient, or in joules per centimetre. But to maintain an induction density B in air requires a gauss-gradient B/μ_0, hence we might write the pull across an air-gap $N^2 \div 8\pi\mu_0 A$. If the induction density across an air-gap is expressed in microwebers per square centimetre, the tension there comes out in units, of which 2,500 would make an atmosphere, or, roughly, in pounds per square foot.

As for the strength of a magnetic pole—a quantity which, though fundamental in one sense, is seldom really dealt with - it will naturally be expressed in ergs per gauss, or in joules per gauss if it is very strong.

Mr. Baily's chief practical suggestions are first that a special unit of permeance, other than the henry, is desirable, and next that the $4\pi/10$ had best be thrown on to the μ so as to keep the gauss equal to one ampere-turn. The fact that the inductivity of air will then cease to appear in its artificial garb of unity may even be regarded as a positive advantage, because its existence will then be less likely to be ignored. But I much fear that the ampere-turn as unit of gaussage, so near the C.G.S. unit in size and yet not equal to it, will be awkward and may lead to mistakes.

O. J. L.

University College, Liverpool, January 15, 1895.

Dear Prof. Lodge,—In reference to the sizes of the magnetic units proposed by you, I find that the weber 10^8 C.G.S. would only be used in fractions. The largest dynamo that I know of has a magnetic flux, or, as you propose to call it, an induction of ·5 weber. From this the value will go down to about ·01 in small motors. These figures are, however, by no means inconvenient.

Transformers will be rather smaller. In these the weber-turn is a convenient size and an interesting quantity, as it is given by $\frac{1}{4}$ *of the mean volts per cycle*, or, more accurately expressed, *mean volts per unit frequency* ÷ 4. Its numerical value will lie between, say, $\frac{1}{4}$ and 50, according to the volts and the frequency, but it gives no indication of the size of the transformer.

The henry 10^9 C G.S. is also large. The inductance of choking coils would, in general, be fractions of a henry. The inductance of the winding of a transformer has no very important meaning, but it has a convenient size. Measuring it as *mean volts of unit frequency ÷ four times the open-circuit current in amperes*, the inductance of the primary coil on a 2-h.p. closed magnetic circuit 1,000-volt transformer would be about 40 henries.

The inductance of pairs of cables would run from 100 to 1,000 micro-henries per kilometre, but the value would vary with the arrangement.

The induction per unit area is good ; having a value in practical work from 1,000 to 20,000 C.G.S. units it is given by 10 to 200 microwebers per square centimetre.

Gaussage would be about 50 in small transformers, up to 40,000 in large dynamos. The latter could be conveniently reckoned in kilogausses. To make the gauss = one ampere-turn appears to have great advantages in practice, and connects it directly with its usual source.

The idea of permeance is very useful, and the identification of its dimensions with those of inductance is neat. But I think it is liable to cause confusion, for the permeance of the core of a coil will be a different number of henries from the inductance of its wire. Moreover, the argument as to identical dimensions might equally be applied to the case of amperes and gausses. I would therefore have a new unit strictly connected with the henry, so that inductance = n^2 × permeance in a coil of n turns.

As to the units of permeance : with the above meanings of gauss and weber the permeance of a circuit would be $4\pi\mu A/10l$, as you point out, instead of $\mu A/l$. But I wish to suggest a change in the method of reckoning—namely, still to retain the value of the permeance as $\frac{\text{webers}}{\text{gausses}}$, and permeability as $\frac{\text{webers per sq. cm.}}{\text{gausses per cm.}}$, therein giving up the convention of unit permeability of space, and giving it the value $1{\cdot}2566 \times 10^{-8}$ unit of permeance for a unit cube. In this way both the troublesome 10^{-8} and $4\pi/10$ are dealt with in an easily intelligible way. To avoid the high power of 10 it may be measured in micro-units of permeance, so that permeability of space and air = ·012566 micro-unit of permeance for a unit cube, and permeability of soft iron = up to 25 micro-units for a unit cube. Thus we have permeance = $A\mu/l$, where μ is to be obtained from tables of its value, which can easily be altered to this method. Inductance then becomes $\frac{\text{weber-turns}}{\text{amperes}}$, or $n^2\,\frac{\text{webers}}{\text{gausses}} = n^2$ permeance.

[Of course, your phrase "weber-turns per ampere" means the same as the above webers ÷ amperes, and does not necessarily mean the weber-turns caused by one ampere.]

It may be objected that the C.G S. units of strength of field, unit of magnetic pole, and intensity of magnetisation do not bear any simple relation to these practical units. This is chiefly important in the use of the magneto-metric measurement of iron, and in the measurement of the mechanical form of attraction between two magnetic surfaces in contact. But the expressions are not in reality much complicated—*e.g.*, present C.G S. unit of intensity of magnetisation is given by $4\pi I = (\mu - \mu_s) H$ where μ_s = permeability of space = 1, and H = C G.S. unit of magnetic force This becomes $4\pi I = (\mu' - \mu'_s) H' 10^8$, where H' is the gauss-gradient in the magnetic substance, and μ'_s = ·012566 micro-unit of permeance for a cubic centimetre.

As the single magnetic pole is unchanged, the force on it will be = strength of pole × gauss-gradient × 1·2566 ; but as this is not a calculation of frequent occurrence, except in magnetic surveys, the complication will not be serious. Other magnetic relationships are almost entirely of academic interest only, and would be carried out in C.G S units. Also, the transition would present no difficulties to people with a little scientific knowledge.

I am of opinion, also, that as the legal volt has no direct connection with induction and velocity of motion, it is not necessary to define the practical units as they are defined absolutely—that is, ohm and ampere are the starting points, volt is obtained from them, weber from volt, gauss from ampere, permeance unit from weber and gauss, henry from weber and ampere or from permeance, and so on This is much more easily explained to practical and unscientific men than the absolute derivations are, and it is the order in which they learn them.—Yours very truly,

FRANCIS G. BAILY.

Postcript.

Another subject for discussion is whether L had better not be defined as $d\,N/d\,C$; with permeability as $\mu = d\,B/d\,H$ to correspond. This would make the three preceding equations stand thus :

$$(1)\ N = \int L\,d\,C.$$

$$(2)\ E = L\,\dot{C}.$$

$$(3)\ \dot{W} = C\,\dot{N}.$$

A letter just received from Mr. Heaviside indicates that he would probably favour this course, and there is evidently much to be said for it I need hardly add that he contemns my temporising method of dealing with the 4π nuisance.

January 30, 1895. O. J. L.

CONTRACTS FOR ELECTRICAL SUPPLIES.

CONTRACTS OPEN.

Posen.—Tenders are invited by the State Railway Authorities for the supply of 90,000 carbon pencils. Conditions for 50pfg. from Die Königl. Eisenbahn-Direktion, Posen.

Ploesti.—The Municipality of Ploesti invites tenders by January 15 for the lighting by electricity of the 46 principal streets in the centre of the town. Conditions from La Mairie de Ploesti, Roumania.

Brussels.—The Ministère de la Guerre invites tenders by January 15 for (1) a heating installation, (2) electric lighting in the new military school to be constructed in the Avenue de la Renaissance, Brussels.

Aussig.—The communal authorities propose to have built a seven-mile single line tramway. The choice of system is left open. Contractors are invited to place themselves in communication with the Stadtrath, Aussig-a.-d.-Elbe, Prussia. Tenders are to be in by January 31.

Wigan.—The Corporation invite tenders for the erection of a dynamo-house and boiler-house for the generating station of the proposed Corporation electric lighting works, for the Gas and Electric Lighting Committee. Drawings may be inspected, and copy of specification, conditions of contract, and bills of quantities obtained, on depositing £2. 2s., which will be returned on receipt of a bona fide tender, on application to Mr. Jos. Timmins, engineer, Wigan. Tenders, sealed and endorsed "Dynamo-House, etc.," to be addressed and delivered to Mr. J. J. Charnock, town clerk, by 20th inst.

St. Pancras (London).—The Vestry invite tenders for the wiring and other work in connection with the electric lighting of the Vestry Hall and offices in Pancras-road. Specification and conditions of contract can be obtained at the Electricity Department Offices, 57, Pratt-street, N.W., on payment of £1, which will be returned on receipt of a bona fide tender; and a plan of the general positions of the lights can be inspected at the office of the borough engineer at the Vestry Hall, Pancras-road. Tenders to be sent to Mr. Albert E. Pycraft, chief clerk, Electricity and Public Lighting Department, 57, Pratt-street, N.W. endorsed "Tender for Wiring Vestry Hall and Offices," by 12 noon on the 16th inst.

Shoreditch (London).—Tenders are invited for the supply and erection of buildings, including an engine-house, offices, and building enclosing dust destructor (the dust destructor being included under another contract), for the Vestry of St. Leonard, Shoreditch. Specifications, bills of quantities, and forms of tender, and any additional information can be obtained from the engineers, Messrs. Kincaid, Waller, and Manville, of 29, Great George-street, Westminster, S.W., on payment of £3. 3s., which sum will be returned when a bona fide tender is received by the Vestry. The plans can also be inspected by intending contractors at the offices of the engineers. Sealed tenders shall be sent to Mr. M. Mansfield Robinson, Shoreditch Town Hall, Old-street, E.C., endorsed "Electric Light Station, Tender for Buildings," at or before noon on 20th inst. The contractor whose tender is accepted shall enter into a formal contract under seal with sufficient sureties for the fulfilment of contract.

RESULTS OF TENDERS.

Cambridge.—The tender of Mr. J. O. Vinter, Hills-road, at 13s. 6d per ton for the supply of 1,000 tons of steam coal for the Cambridge Electric Supply Company, Limited, has been accepted.

Loughborough.—The Town Council have accepted the tender of the Brush Company to supply a dynamo and engine for £80, and lamps and fittings for £43. 2s. 6d., in accordance with specifications.

Islington (London).—The tender of Messrs F. A Glover and Co. for electric lighting of the Agricultural Hall has been accepted. Besides incandescent lighting there are to be 45 arc lamps, together with large mains for supplying current for the various exhibitions.

BUSINESS NOTES.

Great Northern Telegraph Company.—For the month of December the receipts were £26,000

Macroom (Cork).—It is stated that Messrs. Baldwin and Co. and other shopkeepers intend adopting the electric light.

Portsmouth.—Orders have been given for lighting the workshops in Portsmouth Dockyard throughout with electricity.

Bilston.—The new baths are lighted throughout by electricity, the plant for generating the current being fixed in the basement.

Newport (Salop).—The Urban District Council are about to take into consideration the question of lighting the district by electric light.

Vacancy.—The Wolverhampton Corporation require an assistant and draughtsman in the office of the electrical engineer. The salary is £100.

Eastern Telegraph Company.—The receipts for the month of December were £71,577, as against £55,598 for the corresponding period of 1894.

Agency.—Mr. H. Grunwell, M.I.C.E., has been appointed by Isles, Limited, Stanningley, Leeds, their London agent for steam and hand cranes, etc.

Clacton-on-Sea.—Notice of motion has been given to the Urban District Council to the effect that proposals be invited for an installation of the electric light at Clacton-on-Sea.

City and South London Railway.—The returns for the week ended January 5 were £1,017, compared with £1,003 for the corresponding period of last year, being an increase of £14.

Worcester.—The Finance Committee of the City Council have recommended the issue of further Corporation stock to raise £1,300 for the electric lighting of the Guildhall and public hall.

West India and Panama Telegraph Company.—The receipts of the Company for the half-month ended December 31 were £2,639, against £1,949 for the corresponding period of last year.

Sheerness.—The activity at the Sheerness Dockyard has been for the past few weeks abnormal, and the electric light has been fitted to the ships and docks to enable the employés to work overtime.

Globe Telegraph Trust.—The directors of the Globe Telegraph and Trust Company, Limited, have declared an interim dividend of 3s. per share on the preference and 1s. 6d. on the ordinary shares.

Bangor (Wales).—The Town Council have decided to apply to the Local Government Board for sanction to borrow £15,000 for the purpose of providing an electric lighting plant for the borough.

Rochdale.—The Town Council have decided to make application to the Local Government Board for sanction to borrow £500 for the purpose of lighting the free public library with electricity.

Newcastle.—A meeting of ratepayers has been called to consider the question of the offer made by the British Thomson-Houston Company, Limited, to equip and work the tramways by means of electricity.

Western and Brazilian Telegraph Company.—The receipts for the week ending January 3, after deducting 17 per cent. payable to the London Platino-Brazilian Telegraph Company, amount to £2,640.

India.—Schemes have been sanctioned for a telegraph line from Howrah to Cuttack and from Midnapur to Sini at a cost of about 3¾ lakhs of rupees, and along the Delhi Batinda-Samasata line at an outlay of about four lakhs.

Yeadon (West Riding).—The District Council having taken the opinion of the ratepayers on the question have decided not to adopt electric lighting. More than half the number of the voting papers were returned in blank.

Liverpool Overhead Railway.—The traffic receipts of this railway for the week ending January 5 amounted to £1,150, as compared with £926 in the corresponding week of the previous year, being an increase of £224

The Stock Exchange List.—Application has been made to the Stock Exchange Committee to allow the St. James's and Pall Mall Electric Light Company, Limited, £50,000 4 per cent. debenture stock to be quoted in the official list.

Helios-Ehrenfeld Aktien-Gesellschaft.—The general meeting has decided to increase the Company's capital to 3,000,000 marks. The *Elektrotechnischer Anzeiger* says that the net profits amount to 165,000 marks, so that an 8 per cent. dividend is possible.

Telegraphs in Siam.—The head of the Siamese Public Works Department has left Bankok for Tavoy to enquire into the constant telegraphic interruptions between Burma and Siam, and to make arrangements for improving the maintenance of the line.

Submarine Cable in Cuba.—The Spanish Government has laid a submarine cable connecting the principal ports of the island in order to avoid the delay in the transmission of news caused by the cutting of the land wires by small groups of mounted insurgents.

Clontarf.—The Southern District Tramway Company have applied to the Commissioners of the Clontarf Township for permission to extend their electric tramway into the city. The Board have not yet given their consent, but they have expressed their approval of electric traction.

Newcastle.—Mr. Laws, the borough engineer, Alderman Winter, chairman of the Town Improvement Committee, and Mr. Morton, chairman of the Tramway Committee, have been instructed to proceed to Bristol to examine the electrical railway laid there, and report to the Tramway Committee.

A New South American Cable.—A new concession has been applied for to establish a submarine cable, which, starting from Monte Video, shall cross to Buenos Ayres, and then pass down the coast of the Argentine Republic to Santa Cruz, from which point it is intended that it shall strike across to the Falkland Islands.

Eastern Extension Telegraph Company.—For the month of December the receipts show an increase of £9,348, as compared with the corresponding period of 1894. The interest on the 4 per cent. mortgage debenture stock for the half-year to January 31 will be paid on February 1. The stock-register will be closed from 28th to 31st inst., inclusive.

The Export Merchant Shippers' Directory.—We have received from Messrs. Dean and Son, Limited, 160A, Fleet-street, a copy of the thirty-first annual issue of the Export Merchant Shippers' Directory. The section dealing with firms who manufacture principally for export has been augmented, and the number of pages shows an increase on last year.

Digitized by Google

Cheltenham.—The Lighting Committee have reported to the Town Council that during the past month 750 8-c.p. electric lamps have been connected with the town supply, bringing the total up to 5,050, while 500 more were awaiting connection.

Metropolitan Asylums Board.—The Board have received the assent of the Local Government Board to their entering into contracts with Messrs. Siemens Bros., Limited, and Messrs. J. H. Holmes and Co. for the execution of works in connection with the installation of electric light at the Brook Hospital without, in the first instance, advertising for sealed tenders.

Catalogue.—The annual price-list of the Chloride Electrical Storage Syndicate, Limited, comes, as usual, in the form of a neat morocco bound pocket book. Besides lists and descriptions of the chloride cells, it contains careful directions for their erection and working, and a number of tables useful to electricians. It is a well got-up little volume and is properly indexed.

Lincoln.—The Town Council have refused their consent to the grant by the Board of Trade of the provisional order for which the County of London and Brush Provincial Electric Lighting Company, Limited, have given notice of their intention to make application, and a special committee has been appointed to consider and report upon the advisability of supplying electricity in the city of Lincoln.

Direct United States Cable.—The Board of the Direct United States Cable Company, Limited, have resolved upon the payment of an interim dividend of 2s. per share, free of income tax being at the rate of 2 per cent. per annum, for the quarter ending December 31, such dividend to be payable on and after the 24th inst., setting aside £10,000 to reserve fund account, and carrying forward a balance of £4,148. 14s. 4d.

Brussels.—It is stated that, in order to prevent the cost of wiring deterring customers from adopting the electric light, the Brussels authorities have decided to wire consumers' houses at their own expense and recoup themselves by an annual charge added to the bill. One incidental advantage of this system would be that the supply company would no longer be able to complain of bad work inside the consumers' premises.

Ripon.—The City Council have received a communication from the Board of Trade, intimating that, as requested by the Council, they had given notice to Messrs. G. Harrison and Co (who are now supplying the electric light to the Cathedral) requiring them to carry out their works in the city in accordance with the regulations of the Department The Gas Committee have under their consideration the question of lighting the city by electricity.

Blackpool.—It is stated that there will be opposition to the Corporation's Improvement Bill which includes a new line of electric tramways. The Electric Lighting Committee has been reduced to nine members instead of the whole Council. Mr Hesketh was appointed to superintend Messrs. Fowler's contract for the extensions. The Town Council have remodelled the discounts allowed on the 6d. per unit charge for the Corporation's supply of electricity.

Stourport.—The committee which had been appointed to consider the proposed electrical tramway scheme unanimously recommended to the Urban Council that steps be taken to safeguard the public interests. The report was adopted. There appears to be no desire to oppose the Bill generally, but only to see that certain details are altered. It will be necessary to call a special meeting of the Council and a meeting of ratepayers to authorise the expenditure of money for this purpose

Chelsea (London).—The Guardians have received 12 tenders for an electrical wiring installation with fittings in the infirmary extension. Mr. Brass suggested that the tenders should be sent to Mr. Blose and other gentlemen to confer with the architects, as such tenders needed carefully going through. If they accepted the highest tender, it might prove the cheapest, and if the lowest, it might prove the most expensive. Ultimately it was decided to refer the tenders to the General Committee for report.

Leeds.—The Leeds Tramways Committee have decided to visit Westminster for the purpose of inspecting the working of the Westinghouse Electric Company's system, which Dr. Hopkinson suggests should be adopted in those parts of the city where poles and overhead wires are deemed undesirable They expect to be able to lay a definite scheme before the Council early in February. Dr. Hopkinson's report, which proposes an expenditure of nearly £38,000, will be given at length in our next week's issue.

Bristol.—The Sanitary Committee have received a communication from the tramway company with reference to their provisional order for tramway extension, and a separate application in respect of overhead electric traction from Trinity road to Eastville, and have decided to oppose the order in those particulars outside the existing agreement with the committee. As to the proposed extension to Eastville, it was agreed to defer discussion on the subject until a definite proposal had been brought forward.

Calendars.—Among the calendars for 1896, the receipt may be noted of Messrs. Willcox and Co's "Date Remembrancer." This is illustrated with a view of their works in Southwark-street, and some of the more important of their fittings and stores. A similar calendar comes from Messrs. Sankey and Son, Canning Town, E The eleventh annual issue of the "Columbia Calendar" is quite an artistic and handy production, and should appeal to cyclists particularly. It is manufactured by the Pope Manufacturing Company, of Hartford, Conn.

New Companies.—Among the companies registered during December were the Direct Electric General Syndicate, Limited, capital £100,000; Electric Insulation Syndicate, Limited, £10, £5,000; Electric and General Exploring Syndicate, Limited, £5,000; Lightning Express Railway Syndicate, Limited, £100,000; Madeira Electric Lighting Company, Limited, £20,000; New Electric Light Syndicate, Limited, £2,000; Road Motor Association, £1, £15,000; Woking Electric Supply Company, Limited, £1 £20,000; Windsor Electrical Installation Company, Limited, £1, £10,000

Derby-to-Ashbourne Tramway.—The Bill for this electric tramway has been deposited. The company will have a share and loan capital of £87,500 The promoters of the Bill are Sir Henry Wilmot, Bart., V C., C B., the Hon. Frederick Strutt, Mr. Alfred Charles Duncombe, Mr. Godfrey Tranceys Meynell, and Mr. John Shaw, who, with "one other person," to be nominated by them, are to be the first directors of the proposed new company. The Bill contains power to enable the company to pay interest out of capital during the construction of the tramway to an extent not exceeding in the aggregate £10,000.

Edinburgh.—Palmerston-place United Presbyterian Church is the first church in the city to adopt the electric light. The current is obtained from the town's supply, and the scheme of lighting is in accordance with plans prepared by Mr George Balfour, late of the Corporation electric light station, the contractors for the installation being Messrs. Lowdon Bros., Dundee. In all there are 170 incandescent lamps in the building varying from 16 c.p. to 32 c.p. On the report of the Electric Lighting Committee, recommending extensions, coming before the Council, the question was remitted to the Street-Lighting Committee for report.

Sheffield.—The Sheffield Tramways Company are promoting a Bill for power to take up the old tramways and relay them for electric cars, but the Bill provides that the powers of the company to do this shall be suspended for three months from the passing of the Act, so as to give the Corporation within that time an opportunity to decide whether they will be substituted in the place of the company, and work the line themselves. The Bill enables the Corporation, if they think fit, to grant a lease to the company for any term of years, whether exceeding 21 or not. Another Bill seeks to lay down additional tramways in Sheffield at an expenditure of £600 000.

Addresses.—Mr. B. H Thwaite civil engineer and metallurgist, has opened a Westminster office at 29, Great George street, S W.—Messrs Dorman and Smith, manufacturing electrical engineers (Salford), have moved their London office from 11, Grocers' Hall-court, Cheapside, E C., to 94, Charing Cross road, W.C.—Mr. C A. Hemingway, of 10, Petersham-road, Richmond, Surrey, who has carried out a number of installations in Richmond and the neighbourhood, in order to meet the increased demand of his London connection, has opened offices at 39, Victoria-street, Westminster, S.W. Both the Richmond and London office will be connected to the National Telephone Company's system.

Chelmsford.—In reference to the fire at the Arc Works and the lighting of the town, Councillor Britton, at the meeting of the Town Council, said the electric lighting company had endeavoured to do everything they possibly could, and in trying to please everybody they seemed to have pleased nobody. The traders of the town were entitled to some consideration in the matter of lighting, and this they got, but the traders broke faith with the company, with the result that there was neither public nor private lighting on Christmas Eve, when it was much needed. Everything possible was, however, being done, and it was hoped shortly to have all the lights, both public and private, running satisfactorily.

The Transvaal Government.—"One Who Knows" writes to the *Standard* defending the action of the Government of Pretoria in interdicting the use of English plant in its electric lighting. "The electric lighting of Pretoria," he says, "under Government management, has been in full operation for more than two years; but the original plant, which was sent from England, proved to be of very inferior quality, and is already worn out. It is but natural, therefore, that the Government of Pretoria should get their new plant from some other country." The implication that English firms cannot be found who will supply a good installation shows how hard put to it for an excuse the friends of the Boer Government must be.

Sheffield.—The solicitors to the Sheffield District and Rotherham Tramways Company are asking the Corporation for a lease for the existing tramways for 28 years They offer to continue the payments now made by the existing tramway company, amounting altogether to £2,985 7s 8d per annum, and to pay in addition during the 28 years £6 500 per annum; to reconstruct the existing lines of the Corporation for the purpose of electric traction, at an estimated cost of £54,000, the whole benefit of which will at the expiration of the lease revert to the Corporation without payment; and, further, to extend the tramways by the construction of an additional 19 miles at an expenditure of over half a million of money. The system the company propose to adopt is that of overhead electric traction.

Belfast.—On the report of the Electric Lighting Committee coming up in the Town Council, Councillor Andrews, replying to questions, said that the new engines would probably be delivered in the early part of February, and he did not think it would take long to get them into working order With regard to a question as to there having been no statement of the income of the committee, the Lord Mayor himself had stated in his address that the electric installation up to the present, or up to the end of the year, had shown an actual working profit of about £300 or £400. All the demands the committee were capable of complying with had been complied with. In answer to a further question by Councillor Young, Councillor Andrews said the new dynamos would be driven direct; the others were couple-driven by ropes.

Digitized by Google

Hampstead (London)—The Vestry have decided to lay mains for the supply of electric current to private consumers in Redington-road, Goldhurst-terrace, and Canfield-gardens. In reply to a question, it was stated that the cost of the globes affixed to the arc lamps in Finchley-road was 15s. each An offer was made by a firm to supply them for 12s. each, but the committee had been unable to obtain any at that price The care of the arc lamps has been handed over to Messrs. Siemens for eight weeks in accordance with the arrangement sanctioned at the previous Vestry meeting Mr. Evans, as a private consumer, enquired as to the cause of the stoppage of the light on Monday evening last week, and the engineer said that the stoppage was due to the fact that a fuse in one of the machines at the central station blew out and was not noticed as quickly as it should have been.

Weybridge.—A sub-committee of the Urban Council have met Mr. Martindale (representing the Weybridge Electric Supply Company) at the offices of the Board of Trade, and had an interview with Sir Thomas Blomfield to discover if, in the event of the Council purchasing the provisional order, the operation of it could be suspended for, say, three years. Sir Thomas Blomfield replied that the Board of Trade had no power to grant permission for suspension of the order. He further stated that it was open to anyone to apply for another order on the annulment of that now held by the Weybridge Supply Company, that the probable cost of a new order would be £200, and that it would take 12 months to obtain one. Under these circumstances, the committee recommended the Council to discontinue the negotiations for the acquirement of the Supply Company's provisional order. It is possible, however, that a purchaser has been found for the company's undertaking, and, if so, there is a strong probability that the cables and wires will soon be in use again in Weybridge.

Alsager (Stoke-on-Trent).—The Urban District Council have again discussed the question of lighting the village. Mr. J. Maddock, J.P., in accordance with notice of motion, moved that it was desirable to light the village by electricity, and that steps be taken for that end during the present year. Such a scheme would, in his opinion, be of advantage to the village and the ratepayers generally. He thought it would be a backward step to adopt gas-lighting. Mr. Barker seconded the motion. Mr. Cotton moved as an amendment that a poll be taken of the village, which was seconded by Mr. Morris: but after a short discussion the amendment was withdrawn, the original motion being carried. Mr. Cotton then moved that no steps be taken in the matter until the ratepayers had been consulted, this being the condition upon which he withdrew his amendment Mr. Morris also seconded the resolution, which was carried unanimously. The resolution is consequent on a report of Mr. G. R. Peers, A.I.E.E., consulting engineer, of Manchester, who has visited the district, submitted a scheme for the proposed installation, and also addressed a ratepayers' meeting.

Bristol.—The Stapleton Urban District Council have resolved that the chairman and clerk should together formulate and forward to the Board of Trade the Council's ground of opposition to the provisional order sought by the Great Western Electric Light and Power Company for powers within the district. The Chairman (Mr. Daniell) mentioned that he had received a letter from Mr. D. Travers Burges, on behalf of the Bristol Electric Lighting Committee, stating that, as the Corporation were proprietors of an electric lighting undertaking within the district, his committee had requested him to enquire whether the Council intended to oppose the application of the company referred to, and, if so, as to the nature of such objection. The Chairman said he scarcely thought they should be asked to give the information asked for by the town clerk There was a large question behind this matter—the question of boundaries—and Bristol of course, did not want them to enter into any arrangements with the company while they were desirous to take Stapleton into Bristol. It was decided that the clerk should reply to the letter that the Council had the matter under consideration.

Langhans-Berrenberg-Chaplin Patents, Limited.—This Company was registered on December 31 by Templer, Down, and Miller, 3, Pope's Head-alley, E.C., with a capital of £175,000, divided into 175,000 shares of £1 each. Object: to adopt and carry into effect an agreement expressed to be made between Albert Myers Gibson, on the one part, and this Company of the other part; generally to carry on the business of manufacturers of incandescent or other electric lamps, and of all filaments, wires, bulbs, and other parts and requisites of such lamps; to manufacture all such pumps, plant, and appliances as may be necessary to or useful in the manufacture of such incandescent lamps or parts thereof, and to carry on the business of an electric light company in all its branches; to construct, lay down, establish, fix, and carry out all necessary cables, wires, lines, accumulators, lamps, and works; also as mechanical and general engineers, etc. The signatories are: H. L. Pilkington, 76, Jermyn-street, S.W.; P. J Miller, 3, Pope's Head-alley, E C; T. L. Down, 3, Pope's Head-alley, E.C.; W. A. Smithe, 6, Old Jewry, E.C.; D. S. Porteus, 23, Eccleston-square, S.W.; A da Costa, 16, Hyde Park-gate, S.W.; W. Wallace, 27, Old Broad-street, E.C. The registered office is 3, Pope's Head-alley, Lombard-street, E.C.

Brighton.—The new electric elevator at the town hall was supplied by the Otis Elevator Company, Limited, and is one of the best and largest of electrically-driven lifts erected in this country. The car is 6ft. by 6ft., and will accommodate 12 passengers at one time. It is operated by four of the best wire cables ¼in. in diameter—two for lifting and two for independent counterbalance—each capable of sustaining a load of 8,000lb. Two of these cables are independently attached to the safety appliances under the car, which are so arranged that the breakage of one or both of the cables will immediately lock the car firmly upon the guides and prevent its descent, while allowing of its being raised. There are other patent automatic safety appliances attached to the car and to the electric motor, which is situated at the top of the shaft, to provide against obstruction or anything untoward happening. The lift has been built at a cost of about £550, and is a part of the alterations to the town hall, which are now being carried out in accordance with plans prepared by Mr. May, the borough engineer and surveyor. The electric lighting of the main streets has proved a great success, and the Electric Lighting Committee of the Corporation have now under their consideration a scheme for extending the system to many of the less important thoroughfares.

Pole-Finding Paper.—We have received another example this week of those small things which tend to make the electrical engineer's professional life easy. A pole finding apparatus is not so very often required but when it is wanted it is essential that some handy and reliable method should be at hand. The old and cumbersome devices of polarised voltmeters and electrolytic cells are much too cumbersome and costly to compete against the more recent pole-finding papers. The sample we have before us was manufactured by Mr. A. H. Avery, of Tenterden. It is not absolutely a new invention, but careful investigation has resulted in a paper which is very sensitive and absolutely non-poisonous. Its sphere of utility is not confined alone to electrical manufactories or lighting installations for it will be found of great value to amateurs in all kinds of electrical experimental work. By the use of one of these "pole finders" the possibility of wrong connections may be entirely avoided, and such things as reversals of dynamos, motors, accumulators, etc., which are sometimes costly mistakes, will then with care become things of the past. This paper, when moistened and placed across the poles of the dynamo or battery, shows a black mark at the positive pole. We feel sure that this article will find a ready demand, and will in some measure reduce the troubles of all electrical engineers.

Waterloo to Baker-street Railway.—The promoters of the authorised electric railway from Waterloo to Baker-street have deposited a Bill for next session, under which Parliament is asked to authorise a short but important extension westward, in order to effect communication with the Manchester, Sheffield, and Lincolnshire Railway Company's extension to London, and thus give direct access between Waterloo and the terminal station of that company. The Bill also proposes to give power to the former company to enter into working agreements with the London and South-Western Railway Company, the Manchester, Sheffield, and Lincolnshire Railway Company, the Metropolitan Railway Company, and the Waterloo and City Electric Railway Company. By Clauses 11 and 12 of the Bill the original scheme of constructing this railway, as a whole, is proposed to be modified by constructing the railway as three separate "undertakings," each having a separate and distinct capital. "Undertaking" No. 1 will comprise the line from its western terminus to the southern end of Langham-place, and have a share capital of £330,000. "Undertaking" No. 2 will commence at the southern end of Langham-place and terminate at the southern end of Regent-street, and have a separate share capital of £270,000. "Undertaking" No. 3 will consist of the remaining portion of the scheme to Waterloo Station, and will have a separate capital of £650,000. The time for the completion of these railways, as originally authorised, is sought to be extended until March, 1901, which is three years beyond the time originally granted. During the period of construction it is now proposed to pay interest out of the capital allocated to each separate undertaking, provided that the aggregate amount so paid does not exceed in the whole £120 000. In consequence of the powers sought in this Bill, it is proposed to increase the authorised share and loan capital of the company from £1,666,000 to £1,766,000.

Wallasey (Cheshire).—On the Gas and Water Committee's report coming up for confirmation in the Urban District Council, Mr Ellery, in moving its adoption, said the engineer now proposed to establish a trunk line for the electric lighting of the district. The scheme provided for nearly the whole of the district, and would cost £12,500. For this they would have plant on the high-tension alternating-current system, working at 2,000 volts, reduced by transformers to feed low-pressure mains. Transformers would be fixed at New Brighton, Egremont, Seacombe, Liscard, and Wallasey. The generating station would be on the site of the Liscard pumping station, with mains through Liscard, down Manor-road, Seabank-road, Rowson street, and Victoria-road; also along Warren-drive and Grove road to Wallasey Station; Manor-road, King-street, Trafalgar-road, Brighton-street, and Church-road to Seacombe Ferry. He hoped the Board would appreciate the advantages of electricity and adopt the scheme. Mr. Dunn supported on the understanding that Wallasey village should be included. Mr. Burrows opposed on the ground that the work could not be done for the money. The Chairman also thought it would cost very much more. Mr. Herron strongly opposed on the ground that the work could not be done for less than thrice £12,000. He thought they should have the opinion of an expert and get a proper estimate before entering on the scheme. They had been spending enormous sums of money recently, and this would be a further burden, coming just after establishing new gasworks at a very heavy expense. Mr. Paxton proposed that the question should be referred back until expert opinion was had. Mr. Herron seconded. Mr. Joyce said ample expert opinions had been taken, and the gas engineer was quite satisfied with the accuracy of the estimate. Mr. Ellery, in reply, said they would never have heard anything of the amendment if it had not been that Mr. Herron was taking steps to have the electric light

Digitized by Google

at the ferry. The amendment was lost by five votes to fourteen, and the minutes were then passed. Mr. Ellery said if the estimates they would get exceeded the sum named the committee would at once take the Council into their confidence. The report was adopted.

PROVISIONAL PATENTS, 1895.

DECEMBER 23.

24577. **Improvements in movable supports for movable flexible electric conductors.** Thomas Laurie, Wellside-terrace, Falkirk.

24578. **Improvements in the application of electricity to vehicles on tram and railways, and in the apparatus for effecting the same.** David Urquhart and Frank Wynne, 17, Victoria-street, Westminster.

24594. **Improvements in electric lifts.** John Sanders Stevens and Charles George Major, Janus Works, Queen's-road, Battersea, London.

24618. **Improvements in telephony.** Charles Adams-Randall, 63 Chancery-lane, London.

24622. **Mercury gravitation safety-valve and pressure gauge for kitchen and ocrtain low-pressure boilers for electric and machinery engines and water-heaters.** Charles Mackintosh, 159, Euston-road, London. (Complete specification)

24630. **Improvements in dynamo-electric and electro-dynamic machines.** William Hensley Tregaskin, 191, Fleet-street, London.

DECEMBER 24.

24680. **Improvements in electric lighting of cycles, carriages, and other vehicles, and portable and any other lamps.** Phineas Henry Emmanuel and Harry Gage Baker, 12 Ordnance-row, Portsea, Hants.

24706. **System of electric telegraphy and central-station connections and apparatus therefor.** George Croydon Marks, 18, Southampton-buildings, Chancery-lane, London (Wm. H. Cooley, United States.) (Complete specification.)

24710. **Improvements in lightning arresters for high-potential electric circuits.** James Devonshire, 70, Chancery-lane, London (William B. Potter, United States.) (Complete specification)

24711. **Improvements in or relating to electric brakes.** James Devonshire, 70. Chancery-lane, London. (William B. Potter, United States) (Complete specification)

24716. **Improved switch for tramways, electric railways, and the like.** Ludwig Pritzius and Fritz Straube, 31, Southampton-buildings, Chancery-lane, London. (Complete specification.)

24735. **Improvements in electric arc lamps or lighting apparatus.** William Henry Smith, 11, Southampton-buildings, Chancery-lane, London.

DECEMBER 27.

24800. **Improvements in and relating to electric light adapters for oil lamps and candlesticks.** John Black Meiklejohn, 136, Bothwell-street, Glasgow.

24834. **Improvements in electric accumulators.** Charles Théryc and Alfred Oblasser, 45. Southampton-buildings, Chancery-lane, London. (Date applied for under Patents etc., Act, 1883, Section 103, June 28, 1895 being date of application in France.)

34836 **Improvements in electrically-operated windlasses.** Georg Asmussen, 45, Southampton-buildings, Chancery-lane, London. (Complete specification)

24837. **Improvement in the method and apparatus for washing alkali-amalgam obtained in electrolytic apparatus.** Peter Jensen, 77, Chancery-lane, London. (Henrik Christian Fredrik Störmer, Norway.)

DECEMBER 28.

24851. **Development and combination of the telephone and the phonograph.** Jules Ernest Othen Kumberg, 48, Brondesbury-road, Kilburn, London.

24852 **Insulating material for electrical purposes.** Walter Poynter Adams, Furze Cottage, Roehampton, London.

24868. **Improvements in recording instruments for telegraphic and other purposes.** William Thomson, Baron Kelvin, 154, St. Vincent-street, Glasgow.

24884. **Automatic switch for electric water-heater.** John William Ewart and George Ewart, 77, Chancery-lane, London.

24885. **Improved apparatus for electrically controlling the supply of gas and other fluids, and for like purposes.** James Randolph Courtenay Gale, 21, Finsbury-pavement, London.

24888. **Improvements in hinges or joints for electrical purposes.** George William Goldring, 97, Newgate-street, London.

24905. **Improvements in and relating to telephone transmitters.** Thomas Joseph Rorke, 45, Southampton-buildings, Chancery-lane, London. (Complete specification.)

24892. **Improvements in regulators for dynamo-electric machines.** P. R. Jackson and Co., Limited, and Joseph Slater Lewis, 31, High Holborn, London.

24895 **Improvements in dynamo-electric machines.** P. R. Jackson and Co , Limited, and Joseph Slater Lewis, 31, High Holborn, London.

DECEMBER 30.

24945. **Improvements in and relating to carbon-holders for electric arc lamps.** Henry James Fisher, 70, Chancery-lane, London.

24949. **Improvements in electric arc lamps.** Samuel Sealy Allin, 28, Southampton-buildings, Chancery-lane, London.

DECEMBER 31.

25002. **Improvements in electrolytical apparatus.** Richard Heathfield and William Stepney Rawson, 1, Leadenhall-street, London.

25053. **Improved combined portable electric lamp, switch, and battery.** Richard Thomas Glover and John George Glover, 166, Fleet-street, London.

SPECIFICATIONS PUBLISHED.

1887.

14024. **Secondary batteries, etc.** De Benardos. (Second edition.)

1894.

16686. **Galvanic cells.** Vogt.

646. **Voltaic batteries.** Walker and others. (Second edition.)

1895.

148 **Measuring electric currents.** Shallenberger.

1477. **Arc lamps.** Bevis and Binswanger.

2343 **Electric incandescent lamps.** Pope. (Pope.)

2570. **Chandeliers, electroliers, etc.** Meason and Ford.

2604. **Arc lamps, etc.** Crompton.

17495. **Electrical heating apparatus.** Feeny. (H. W. Johns Manufacturing Company.)

19862. **Dynamo-electric machines.** Devonshire. (Thomson.)

20215. **Galvanic batteries.** Boynton.

20216 **Galvanic batteries.** Boynton.

20306 **Storage batteries.** Langelaan.

20431. **Secondary batteries.** Rooney.

20807. **Electrotypes or galvanos.** Mayer.

NOTES.

Madras Tramways.—The second section of the Madras electric tramways constructed on the overhead system has been opened for traffic.

Legion of Honour.—The names of MM. Henri Moissan and Arsène d'Arsonval appear in the New Year's list of advancements to the grade of officer of the Legion of Honour.

Electric Tramways in Belgium.—According to the Brussels *Moniteur des Finances*, the Ministry of Railways has decided to refuse for the present to authorise electric traction on the overhead system in Brussels in consequence of the objections raised by the telegraph and telephone administrations.

Manganese and Silicon.—A definite silicide of manganese can be prepared by means of the Moissan electric furnace. M. Vigoureux, who has been investigating its properties, states that its composition corresponds to $SiMn_2$. The compounds of silicon with nickel and cobalt previously prepared had a similar formula.

American Motor League.—The newly-elected executive committee of this association has selected Mr. C. E. Duryea, of Peoria, Illinois, as president. The headquarters of the league are at 335, Dearborn-street, Chicago, and its purpose is to advance the interests and use of motor vehicles. It intends to contest adverse judicial decisions, and to influence legislation as to the use of motor vehicles in America.

The South African Cables.—On Wednesday it was announced that there was a breakage in the telegraph cable between Bathurst (Gambia) and Accra, so that news of the Ashanti expedition could only be obtained by way of the Cape and Aden at largely-increased cost. This failure, following so closely on that of the eastern route to South Africa, shows that there is at any time a serious possibility of losing touch with the South African Colonies altogether, in spite of the alternative routes.

Royal Meteorological Society.—The annual meeting of this society was held on the 15th inst. at the Institution of Civil Engineers, Mr. R. Inwards, F.R.A.S., president, in the chair. The report of the council showed that the society was in a satisfactory condition, 34 new Fellows having been elected during the year. Mr. Inwards devoted his presidential address to the subject of "Meteorological Observatories." The address passed under consideration the various types of observatories, including the most recent class—namely, those on high towers. Mr. E. Mawley, F.R.H.S., was elected president for the ensuing year.

Horseless Carriages.—The Highland and Agricultural Society have accepted an offer of the Lord Provost of Perth to give £100 in prizes for horseless carriages. In the *Journal* of the Royal Agricultural Society Mr. F. S. Courtney deals with the applicability of self-propelled vehicles in rural districts where light railways would from their cost be prohibitive. "If a self-propelled vehicle can be produced at a reasonable cost, carrying a moderate load at a fair rate of speed along the ordinary public road, such a vehicle must in most instances meet all the purposes of a light railway at a very considerable saving in first cost." Various sources of power—steam, petroleum, and electricity—are discussed.

Acetylene.—It would appear that in Italy it is considered that there is a future for acetylene as an illuminant, judging by the space devoted in last week's issue of *L'Elettricità* to a description of an apparatus for the production of this gas from carbide of calcium and water which has been brought out by the Società Elettrica Industriale, of Milan. The apparatus consists essentially of two vertical cylinders sliding into each other very much like a small gasometer. It is stated that up to the present no trouble has been experienced from the acetylene attacking brass or bronze taps and fittings, with the formation of explosive compounds, as has been anticipated might possibly be the case.

Lugano Tramways.—The *Gazzetta Ticinese* gives an account of the Lugano electric tramways. The current is generated at Maroggia, 12 kilometres (7½ miles) off Lugano, water power being used, derived from the sources of the Arogni. Alternating currents are used. At the generating station at Maroggia there is a 300-h.p. turbine, and 5,000-volt currents are carried on an overhead line to Lugano, and there transformed to 400 volts, "a pressure which," our contemporary says, "is not dangerous to anyone touching the line." The greater part of the article is devoted to explaining theoretical reasons for preferring alternating to direct currents, and beyond stating that the three-phase system is adopted no further details are given.

Bottle-Labelling Machine.—One great difficulty in designing machines for labelling bottles is to devise a mechanism that will detach the top label from a pile, so that it may be subjected to the action of a paste-roller, and afterwards pressed against the bottle. The *Western Electrician* contains a description and illustration of a machine in which this is effected by a solenoid and core worked by a dynamo, the plunger attached to the core being charged statically by an ordinary glass friction machine. It is found, as might be expected, that the regulation of the slight impulse of static electricity required to attract the top label is a matter of considerable delicacy. The machine is the property of Mr. J. F. Small, of Chicago, one of the inventors.

M. Mondon on Voltage.—In the note in our last issue on the subject of a communication of M. Mondon to the Chambre Syndicale des Industries Electriques, translated from *L'Eclairage Electrique*, the equation given in the last lines is obviously incorrect. M. Mondon is urging that permission should be granted to use alternating currents of 250 volts with bare conductors, and substituting for the figure given 1·41—*i.e.*, the ratio of the maximum pressure to the square root of the mean square—the argument becomes: "Admitting that the danger is proportional, not to the effective but to maximum pressure, there would be in that case only (a maximum of) $250 \times 1{\cdot}41 = 353$ volts instead of the 400 volts which are permitted with a continuous current."

To Brighton in Twenty Minutes.—Mr. Hiram S. Maxim contributes a short article to *Cassier's Magazine* on the possibility of propelling trains at very high rates of speed by electric traction. He points out that by this method accelerated speed does not involve such a progressive increase in the weight of the locomotive as becomes necessary when an attempt is made to increase the speed of an ordinary railway train, and he thinks that with suitably constructed rolling-stock a rate of from 90 to 120 miles an hour might be obtained by electric traction. The main idea of the article is to have special electric lines for fast through passenger traffic, leaving the local traffic to be dealt with as now—by steam locomotives. Passengers might then be taken from London to the sea coast in 20 minutes.

Conduit Tramways.—The operation of the conduit electrical railway on the Metropolitan system at New York

Digitized by Google

is being watched with interest by American street railway engineers. As the wet, sloppy weather comes on the real test of the system begins, and *Electrical Industries* (Chicago) says that if it proves satisfactory it will only be a question of time when many cable roads will be changed to electric. Local conditions in many places will, however, limit the use of the underground trolley. "On level streets where the drainage is poor, such systems cannot," our contemporary urges, "be used." As the extremes of the North American climate are more severe than ours, American experience would supply a crucial test so far as weather influence is concerned. Also, the drainage difficulty is one that would not be insuperable in most English towns.

Fusion of Wires.—M. Maurain has presented a note to the Société Internationale des Electriciens on the fusion of metallic wires by continuous currents. M. Maurain says the production of drops on the surface of wires not quite in a state of fusion is generally considered as due to the localisation of the current at the surface of the wire, and to be a consequence of the oscillatory nature of the discharge. He has, however, obtained the droplets with a battery current, and the same results are obtained with a resistance introduced, having self-induction as with one that has little or none. The author suggests that the formation of the drops is a capillary phenomenon produced during fusion, and must be explained in the same manner as the equilibrium figures obtained by Plateau with a liquid in suspension in another liquid of equal density. It is, however, difficult to tell whether the forms obtained in the fusion of wires are forms of equilibrium or unstable forms, the transformation of which has been stopped by solidification.

Birmingham and Midland Institute.—The institute conversazione has been held. There was a large attendance, and many enquiries were made for the horseless vehicle which was to be shown, but unfortunately the adaptors of the Milver batteries to this kind of conveyance were compelled to disappoint the enquirers to a large extent. The carriage, which is of the dog-cart pattern, constructed to carry four persons, possesses as its motive power two Milver primary batteries — the invention of Mr. W. Robatham. The advantage claimed for these batteries is that they economise space and weight by making accumulators unnecessary, and also that the need for charging stations is obviated. These two batteries will move the car, which weighs 1,000lb., at the rate of 12 miles an hour for a distance of 150 miles, but the visitors were not able to judge of their power owing to their having been damaged in transit. The company, however, were able to light the room direct from another lot of their batteries with every success.

Institution of Junior Engineers. — We have received the report of this institution for last year. From comparison of the muster roll at the present time and 12 months ago it is satisfactory to notice that applications for admission to membership, after having received the careful consideration of the council, have resulted in the addition of 56 names to the class of "member," including, however, 17 transferences from the class of "associate." A diminution in the number of associates is accounted for chiefly by these transferences, which were duly made in accordance with the resolution passed at the last annual general meeting, whereby candidates over the age of 26 years may be admitted as "members." The total elections and transferences have been 90, while by death, transferences, resignation, and removal of names the number is 45, resulting in a net increase of 45, the total membership being now 418. So far as finance is concerned, the institution started the year with a small deficit, which has now been converted into a small balance to credit.

Electro-Harmonic Society. — The next smoking concert of this society is fixed for Friday, January 31 at the St. James's Hall Restaurant, Regent-street, W., at eight o'clock. The following will be the programme:— Part I.: duet, "The Battle Eve," Mr. Maldwyn Humphreys and Mr. David Hughes; pianoforte solo, "Menuetto and Finale from Op. 31, No. 3" (Beethoven), Mr. Alfred E. Izard; song, "Mary Adeane," Mr. Maldwyn Humphreys; song, "Revenge," Mr. David Hughes; violin solo, "Ave Maria," Mr. T. E. Gatehouse; serenade, "Aubade," Mr. Albert James; humorous sketch, "A Peculiar Party," Mr. Edward Kent. Part II.: violin and piano, "Andante con Variazioni—Finale" (from the Kreutzer Sonata), Mr. T. E. Gatehouse and Mr. Alfred Izard; song, "By the Waters," Mr. Maldwyn Humphreys; song, "A Soldier's Song," Mr. David Hughes; violin solo, "Hungarian Dances," Mr. T. E. Gatehouse; old song, "Oh! Say Not Woman's Heart is Bought," Mr. Albert James; duet, "Flow Gently, Deva," Mr. Maldwyn Humphreys and Mr. David Hughes; humorous sketch, "Harmony Hall," Mr. Edward Kent.

The American Way.—According to *Invention*, one of the quaintest adaptations of electricity, or, rather, electrical appliances, has recently been made in Chicago. On the line of the electric street railway company in that brand-new metropolis is the great cemetery of Oakwood. Heretofore, funerals have taken place in the normal manner by the means of hearses and the accompaniment of mourning coaches. Now, however, the enterprising tramway company is building funeral cars. These above the tracks will be black; even the trolley poles will be wound with crape. When the deceased is a child, this crape will be white and the sides of the car will be festooned with white. Inside the car, just behind the motorman, a bier will occupy one side. Opposite this are to be seats for the minister and pall-bearers. The mourners will sit along the sides of the car. Funeral parties may charter a train with any number of cars, which will start from any point on the line. A special motorman and conductor will be uniformed in black. Funerals run by electricity are certainly a novelty, and the announcement is somewhat startling to our sense of convention.

Safety Rules.—The absence of a regulating authority as to electrical installations in the United States does not give unqualified satisfaction to the Chicago *Electrical Journal*. Under the system of *laissez faire* the matter practically falls into the hands of the insurance companies. The National Board of Fire Underwriters appreciates its position and keeps up with the times, but it is not all-powerful. Many manufacturers find that much of the material they have on the market is accepted by one office and rejected by others, and users are often compelled to take out material and substitute something else after it has been passed by one or more inspection departments. Inspectors of different authorities cannot be brought to agree. On the other hand, with some sort of national Board, if possible, or, at any rate, one made up of State or municipal representatives, there would be a testing department of men whose knowledge and integrity would be above suspicion. Rules for installation would then be alike everywhere, and it would no longer be necessary for manufacturers to keep in touch with an infinite horde of independent inspectors working under different sets of rules.

Foreign Exhibitions.—The Swiss National Exhibition begins at Geneva on May 1 and terminates on

Digitized by Google

October 15. Mr. Theodore Turrettini, Mayor of Geneva, and a distinguished electrical engineer, is president of the exhibition, and it is expected that the electrical exhibit will be one of the finest ever seen. Mr. Turrettini has recently completed great engineering works near Geneva, whereby the River Rhone supplies 12,000 h.p., to be electrically transmitted six miles to the grounds. This enormous force makes it possible for electrical experiments to be made which cannot be attempted elsewhere. There will be a travelling footpath, operated by electricity, traversing the great machinery hall; horseless cabs driven by electricity, appliances for aerial navigation, a multiplying valve pump, processes for making paper and fabrics, tests of strength on metals, and many other electrical appliances. Prof. Pictet will display his inventions for producing intense cold, showing a temperature of 415deg. below zero, and will exhibit the uses of this low temperature. The Department of Science and Art has received, through the Foreign Office, a communication from her Majesty's Consul at Barcelona stating that it is proposed to hold a fine art and industrial exhibition in that city, beginning on April 23 next. The Science and Art Department has also received, through the Foreign Office, a communication stating that an international exhibition will be held in Brussels in 1897. There is also to be an industrial exhibition in Guatemala next December.

The Rontgen Radiations.—Further information comes from Berlin on the subject of the new radiations contained in the light from a Crookes vacuum tube which were discovered by Prof. Röntgen, of Wurzburg, by their action on a sensitised photographic plate. On reading of the discovery, the German Emperor promptly invited Prof. Röntgen to Potsdam, and the latter gave there a demonstration of the new radiations. He photographed objects which were placed behind panels of wood, and in wooden and cardboard boxes, the rays which photographed the objects passing through the wood or cardboard. The experiment of photographing the human hand was, however, not repeated. On the occasion when this was done before it was stated that an image of the bones only was produced, the flesh not showing, but it must be remembered that the photographs are not camera images but direct "shadow" pictures, and the source of the light—a Crookes tube—is very far from being a mere point. It is stated that the new radiations are not affected by a glass prism, and it was part of the demonstration at Potsdam that they were not sensibly refracted in passing through water. This might reasonably be expected to be the case if, as was suggested last week, the new radiations are really undulations of very long period, but a statement that they also pass through thin aluminium plates is not so easily explicable. Prof. Röntgen himself has not yet advanced any theory on the subject. At the conclusion of the Potsdam experiments the German Emperor invited Prof. Röntgen to supper, and remained with him and other guests conversing about the invention till midnight, when he personally handed Prof. Röntgen the Crown Order, Second Class.

Direct Production of Electricity.—Dr. Louis Duncan, writing in *Cassier's Magazine* on the subject of the direct production of electrical energy, remarks that, in the words of Prof. Borchers, "the problem is the conversion of the energy of fuel (including fuel gases) into electrical energy by oxidation without transforming the energy into heat, and without the destruction of the chemical reagents or the formation of waste products that require regeneration." After dismissing thermo-electric couples and gas batteries as offering no prospect of a practical solution, Dr. Duncan says that for the use of solid fuel in the place of gases many plans have been tried, and a number of patents taken out. It is often stated that some inventor has solved the problem, but such announcements are never followed by performance. "It is not so very difficult to oxidise the carbon. There are a number of batteries which do this, but the oxygen is usually taken, not from the air, but from the electrolyte." It is then urged that if the problem is solved with a solid fuel, the solution will be a simple one. It really means the discovery of a proper electrolyte. Of course, the carbon must be put in the form of a conducting mass, but this can be done for a small sum. Dr. Duncan then continues, "I have experimented upon a number of patented methods, but up to the present time I know of no method that has been publicly described that fulfils the conditions or gives any promise of success. But I have seen a method not patented yet, and, unfortunately, not mine, which does apparently fulfil the conditions, and which gives currents, not measured milliamperes, as is ordinarily the case, but in honest amperes, and plenty of them." The rest of the article deals with what will be the consequences of the solution of the problem, but until we hear what Dr. Duncan's solution is these may be left over.

Gas-Engines.—At a meeting of the Institution of Junior Engineers last week, Mr. H. J. Young in the chair, a lecture on "Problems Connected with the Theory, Working, and Testing of Gas-Engines and Hot-Air Motors" was delivered by Prof. T. Hudson Beare, B.Sc., M.I.C.E. The lecturer began by giving a short account of the early forms of hot-air motors, describing the Cayley, Stirling, and Ericsson motors as representatives of the three classes into which he divided these engines. He gave a *résumé* of the long discussions at the Institution of Civil Engineers on the value of the regenerator, which led to a paper by Sir Wm. (then Mr.) Siemens, entitled "The Conversion of Heat into Mechanical Effect." This was the first time the then novel mechanical theory of heat had been brought before engineers, and a short description of the early gas engines—Lenoir, Otto, and Langen, and other forms—was then given. Dealing next with the possible cycles which can be adopted for hot-air motors, the lecturer gave first a brief summary of the general principles of all heat motors. For each type certain temperature limits had been chosen, and the maximum possible efficiencies and the actual possible efficiencies of each were worked out and shown in a table exhibited to the meeting. The cards for each cycle had also been prepared, and diagrams illustrating an engine of each class, the table and diagrams showing very clearly the large amount of power absorbed by the pumps in most of these engines, to which circumstance was due their low mechanical efficiency. It was also pointed out how poor the average effective mean pressure obtainable was. The actual efficiencies reached in practice were given, and the reasons, both thermodynamical and practical, why these motors failed so to reach their possible efficiencies were discussed. Prof. Beare then proceeded to consider the gas-engine. After indicating the advantages of the De Rochas cycle, he contrasted the small amount of work spent in the pumping stroke in the gas-engine as compared with the large amount it became in hot-air motors. The question of the value of a regenerator in a gas-engine was investigated, and the points illustrated by two fully worked out examples; it was shown that the possible efficiency could be increased by its use, but probably at the expense of making the engine bulkier for a given power by reducing its effective mean pressure during the working stroke. The testing of gas-engines was lastly dealt with, all the observations needed being fully treated; the difficulties in carrying them out, and

Digitized by Google

the best means for ensuring accuracy of results, were mentioned. The lecturer explained how it was possible to work out a complete heat balance for any gas-engine without directly measuring either the quantity of air used or the temperature of the exhaust. It was necessary to assume the temperature of the charge just when compression was about to begin, and it was shown that this must be about that of the jacket-water. This was the only assumption to be made. A discussion followed.

Electrolytic Zinc and Lead. — An article by R. Lorenz in *Zeitschrift für Anorganische Chemie* is summarised in the *Journal* of the Chemical Society. The chief difficulty to be overcome in the electrolysis of zinc chloride is to obtain the salt entirely free from water. The zinc chloride, which still contains water, is placed in a V-tube of combustion glass and heated to quiet fusion. A carbon electrode is placed in each arm of the tube. Directly the current is started a brisk evolution of gas, due to the presence of water, takes place at both electrodes. The gas evolved at the positive electrode is at the commencement hydrogen chloride, but after some time chlorine is evolved. Meanwhile, the evolution of gas at the negative electrode diminishes, and zinc begins to be deposited. During the deposition of the first few drops of metal a brisk evolution of hydrogen takes place at the negative electrode. As the zinc which is deposited at first is not pure, but contains lead and other metals which may be present, the molten electrolyte is poured off into a similar V-tube as soon as the less positive metals have been deposited, and the electrolysis is continued. Pure zinc is then deposited. The electrolyte, which now consists of pure zinc chloride, is a clear, limpid, highly refractive liquid, under which the molten zinc appears like mercury. It solidifies, on cooling, to a white, porcelain-like mass, and is the most hygroscopic substance the author has worked with. Fused lead chloride is easily electrolysed in a similar way. Fused cadmium chloride is not so easily electrolysed; chlorine is at once evolved at the anode, and at the cathode brownish-black clouds which dissolve in the electrolyte, whilst a small quantity of cadmium is deposited. The electrolyte contains a lower chloride of cadmium, which can be obtained as a crystalline metallic powder by lixiviating the electrolyte with water; this compound is difficult to dissolve in hydrochloric acid, and the solution does not at first give a precipitate with hydrogen sulphide, but, after some time, a yellow precipitate is suddenly deposited. In the electrolysis of fused silver chloride, the silver is deposited as a brown mass, and when a small quantity of melted zinc or lead is placed in contact with the cathode, the silver dissolves in the molten metal. Silver chloride dissolves in zinc and lead chlorides, and, on subjecting the mixture to electrolysis, the silver is deposited first. The silver is also deposited when a zinc rod is placed in molten zinc chloride containing silver chloride. Copper chloride, dissolved in zinc chloride, in which, however, it is only slightly soluble, can be electrolysed by employing a cathode of molten zinc, when all the copper is obtained as a zinc-copper alloy. Mixtures of zinc, silver, lead, copper, and cadmium chlorides on fusion give colourless electrolytes, which are easily manipulated. The addition of lead chloride to zinc chloride greatly increases the ease with which the fused salt is dehydrated by heat alone, and magnesium and calcium chloride produce the same effect. When such mixtures of fused metallic chlorides are electrolysed, the metals are deposited one after the other, and can be obtained pure by fractional electrolysis. As the result of these experiments the author has worked out a practical method which he suggests might be adopted for winning zinc and lead from their ores by electrolysis.

Electricity in Medicine.—Dr. W. S. Hedley, the medical official in charge of the electro-therapeutic department of the London Hospital, has communicated an important article to the *Lancet* on the use of "Current from the Main' in medical practice. With reference to the use of dynamo currents, he remarks that "although the current produced by the E.M.F. of the continuous-current dynamo is unbroken and always flowing in one direction, it cannot be said to be absolutely uniform in strength. That is to say, the current obtained, for example, from a single dynamo having a commutator of only a few sections is undoubtedly a 'pulsatory' current. But such are not the conditions that exist in dealing with continuous currents from modern central lighting stations. In the latter case a number of dynamos, usually running at different speeds, and having commutators of numerous sections, are used in parallel with accumulators of large capacity. The current emanating from such a source cannot be called pulsatory. Its line of E.M.F. with the now universal constant-potential system may be regarded as practically straight." Comparing, however, the effects produced by a continuous lighting current of 100 volts, reduced by a resistance in series with the patient with those produced by a Leclanché battery of just sufficient voltage to give the required number of milliamperes, Dr. Hedley remarks that: "It is noticeable that with a dynamo current used through a resistance in series with the patient greater pain accompanies, and a greater skin-reddening follows, the application than when a continuous-current battery is used, and that both effects are decreased by pressing upon the electrode—in other words, by making a better electrical contact. In looking for an explanation of this it is to be remembered that an imperfect contact may have a high E.M.F. across it, and that the heat generated in any circuit or part of a circuit is in proportion to the watts absorbed. This may give rise to considerable local heating. With high-potential currents the available E.M.F. is greater, therefore the possible heating effect may be comparatively great. The importance of a good contact—well warmed, well wetted, and carefully adjusted electrodes—is known to all who use such currents on the living body, especially with imperfect apparatus." If, however, these effects are foreseen and understood they can be obviated. Passing to alternating currents, Dr. Hedley says that a lighting current differs from a true sinusoidal current "chiefly in the comparative irregularity of its curves, an irregularity depending upon the construction of the dynamo, the capacity, and self-induction of the circuit, and other causes. The faradaic current differs from both the foregoing in the fact that its positive and negative maxima are very suddenly attained and are unequal in extent; the current is therefore a dissymmetrical one. From these physical differences arises a dissimilarity in physiological effects. Inasmuch as the excitant action of an electrical current bears a direct ratio to the suddenness of the fall of potential, it follows that the sinusoidal current will be better tolerated than the more brusque alternations of the coil. Also on this account it is equally evident that the latter for certain purposes can never be altogether supplanted by the currents of smoother curves. On the other hand, where effects on general nutrition, rather than on muscular contraction are sought, the latter currents present decided advantages. It has been shown by d'Arsonval that in a person subjected to alternating currents of a sinusoidal character, although the current be scarcely felt and excite no muscular contraction, the nutritive exchanges undergo an augmentation of from 40 to 50 per cent., the 'respiratory capacity' being almost doubled." These effects are probably owing

Digitized by Google

to an influence on nutrition due to the decompositions and recompositions that must ensue on the passage of an alternating current through the tissues. The alternating currents of commerce, partaking as they do of the sinusoidal character, present a means of increasing the nutritive exchanges by a direct action in virtue of their sinusoidal type, and by an indirect action in virtue of the muscular contractions they induce. Applied chiefly through the medium of the water bath, this alternating lighting current is daily employed in practice, and seems to act as a general tonic, and to stimulate the nutritive exchanges. Its employment has been followed by good results in chloro-anæmia, rickets, muscular atrophies of myopathic origin, obesity, gout, sciatica, and rheumatism, the latter in its articular as well as in its muscular manifestations. This current is easily handled for medical purposes, and its use is now by no means uncommon." After describing, with illustrations, apparatus for varying and controlling the voltage and current, it is remarked that "the time ought to be approaching when electricity will be prescribed and administered not only in measured units of intensity, density, and time, but with definite ideas of the shape of the E.M.F. curve and of the therapeutic indications that a given curve may be expected to fulfil." The article is followed by a note on the safeguards that may become necessary when, under the revised regulations of the Board of Trade, currents of considerably higher voltage than are now common come into use.

Worthless Electric Lamps.—"It is my experience," writes a correspondent to the *Daily News*, "that incandescent electric lamps are no longer what they were. They last, as a rule, such a very short time that I am tempted to give up electric lighting altogether and fall back upon gas as being more economical and less annoying, though not so healthy. Can nothing be done to remedy the deterioration which seems to date to the period when lamps became suddenly very cheap, owing, as I believe, to the expiration of the patents?" Special enquiry in well-informed quarters has shown that the above complaint is well justified, but that it cannot apply to the best class of lamps made in England. Mr. W. H. Preece, the electrician and engineer-in-chief to the Post Office, has made a close study of the whole subject. The installation at the Post Office in St. Martin's-le-Grand comprises 10,000 lamps, and the whole number under Mr. Preece's direction exceeds 50,000. He has, therefore, been able to institute photometrical tests of a most elaborate and exhaustive character, and the records of these tests have furnished a mass of data which are in course of arrangement in order that they may be presented to the world in a practical form. Mr. Preece will shortly enable the users of electric lamps to determine in the course of an hour the probable longevity of any lamp. At present no such guide is available to the public, and one consequence has been that cheap electric incandescent lamps, such as are ordinarily bought in a shop, are frequently so faulty in construction that they are speedily used up, and electric lighting falls into discredit because of the cost entailed by constant lamp renewal. The evil which domestic consumers are experiencing here is set down, principally, to German competition. Lamps are, it is true, to be bought for one-tenth of the price paid for them 12 years ago, but they are often not worth the money that is now asked. There is danger, it is said, that further deterioration may take place unless something be done to protect the consumer. In Germany a committee has been appointed to enquire into the reasons for the sad falling off in quality and to find out a way to compel makers to supply good lamps. The recommendations of this body of experts will, it is probable, lead in Germany to the standardising of incandescent lamps, and it is predicted that all the rejected ones will be thrown upon the English market. At the General Post Office no lamp is used that is not of the best English make, and a preliminary test is employed. The household consumer has, however, no means of protecting himself. Mr. Preece says that it is not uncommon for cheap German lamps to be marked as of 100 voltage, when the true voltage is 98. This misstatement, too, it appears, is not due to mere carelessness on the part of the maker, but is an intentional deception; for when a 98-volt lamp is provided with a 100-volt current it is quite evident that it will glow more brightly for a time, its increased brilliancy, however, being obtained at the cost of its shortened "life." To employ a simile, the lamp starts with a balance of, say, 1,000 hours to the good, and it overdraws its account every day, so that its spendthrift existence comes prematurely to an end. Theoretical perfection implies that the voltage—the pressure applied to the electric main and to the lamp—should be equal and constant; but though it ought not to be difficult to ensure that the lamp and the current should be judiciously mated and uniform, the degree of the pressure in main and lamp alike must vary according to circumstances, depending as it does upon the speed of the engine and, in some degree, upon the rate of consumption. Inequality of pressure, however, is less dangerous to the life of a lamp than the attempt which is made by some people, desirous of obtaining a brighter light, to use a lamp of lower voltage than heretofore, and to force through it an unreduced current. When this is done with a cheap German lamp, wherein the operation has been already discounted, the probable lifetime is correspondingly reduced, and the lamp which is supposed to live 1,000 hours does not last for as many minutes. But how is the consumer to forearm himself against the twin risks—that of inequality of pressure and that of too high a pressure? The first he cannot wholly avoid; as to the second risk, at present there appears to be no safeguard against loss except that of buying the best English lamps in the market at, perhaps, double the cost of the cheapest German article. Since lamps of higher efficiency have been introduced as being more economical, the term of their life has been reduced from 1,000 hours to about 800 hours, or under, for a three to three and a-half watt lamp. It is argued that one may have a lamp too long in use. After a while a deposit of soot obscures the inner side of the vacuum globe, which, of course, cannot be cleaned, and the filament itself loses its incandescent power. On that theory people are recommended to renew their lamps more frequently than they do, and not to wait until the lamp gives out completely. The difficulty is to tell when the moment arrives for the economical replacing of the globe, and before this can be determined one must know for how long the lamp should be retained. Mr. Preece's test will be, it is understood, at the disposal of such a body as the St. Pancras Vestry, whose installation was the first of the kind in London. But under the existing system the test could not be employed in St. Pancras, the local authorities having no concern in the supply of the lamps, contenting themselves with producing the current and distributing it to the consumers. There seems to be an idea that if a vestry undertook to "wire" houses, and to sell the proper fittings, a public outcry would be raised against monopoly. Yet, in Mr. Preece's view, the lamps should be furnished by the producers of the current—the one being in intimate relationship with the other.

ELECTRIC RAILWAY PRACTICE IN THE UNITED STATES.*

In the bustle and confusion of a rapidly growing industry, when inventions, new discoveries, and applications follow close upon the heels of others only recently in good repute, when all is strife, eagerness, and emulation, men do not stop to ask themselves, "What have we accomplished?" or "Whither we are drifting?" They say instead, "This one step must be taken or our rivals win." So it has been, and even yet is, in electric railroading. Few things are perfect, few things can be called standard. In spite of all that has been done in these last 10 years, in spite of the fact that within the last five years not less than 1,500,000 h.p. of electrical machinery has been manufactured for railway purposes, the field is broadening with every day's new life, and few can assume to understand how far we shall have to go before we exhaust the infinite applications in the science of transportation where electricity is to find its mission. Yet it is well in the midst of a busy life to pause occasionally and to get a measure of what has been done, and to determine, as far as our wisdom will permit, in what direction our next efforts should be turned for the greatest individual and general profit. It is with the hope of taking some such general survey of the field of electric railroading in the United States that this article is written. An attempt will be made to sift out from the mass of conflicting practice to be found in the United States that which is modern and approved from that which is past and obsolete.

The Overhead Wire System.—The overhead wire system is the only one which has proved entirely adequate and satisfactory in the varying conditions found in American cities—such as the severe storms of the North, the dry and gritty sands and salt, moist breezes of the Gulf States. The road-bed construction is, up to the present, in a state of transition, but the old horse railway track, with its flat side-bearing rails spiked to longitudinal stringers, has gone by for ever. The use of concrete as a substructure for track construction is not as general in America as abroad, although in the principal cities of Canada and a few in the United States it has been used with excellent results, giving much greater solidity and permanency to the track than where the foundation is the natural dirt, gravel, or clay. Wooden ties are reasonably plentiful and cheap in the United States, and are generally used instead of metal ties, which, however, have been recently adopted in Detroit, Terre Haute, and a few other cities, chiefly in the West. The ties are usually placed close together, rarely exceeding 2ft. or 2½ft. centres. Creosote and other preservative compounds are rarely used, it being the general opinion that the life of the tie will be at least as long as that of the rail, but not of double that period, so that in relaying a road bed it would not be advisable to put new rails on old ties, even if the latter were in fairly good condition. Our illustrations show some typical road sections, which may be taken to fairly represent the present practice.

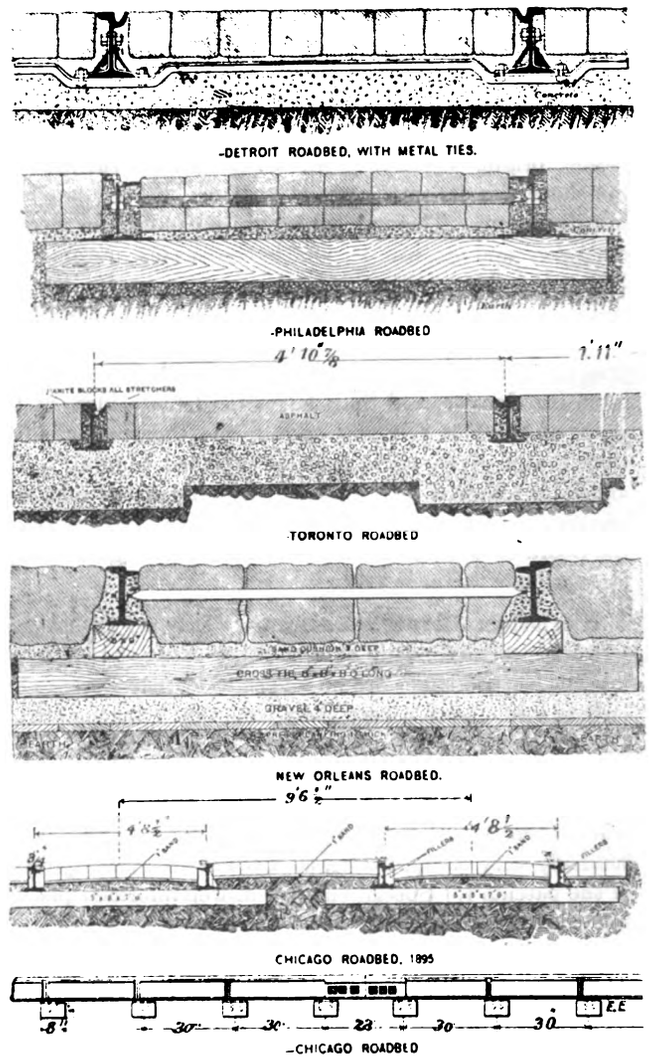
Rail Sections.—Only two or three years ago rails 6in. and 7in. deep, weight 60lb. to 70lb. to the yard, were considered heavy, and were the accepted practice even in the larger cities. These rails were generally mounted on chairs, in order to reach the ties placed just underneath the paving blocks. To-day, however, the chair construction is entirely abandoned. Now, rails from 8½in. to 9in. deep are preferred, and are spiked direct to the ties. The weight of these deep girder rails is now from 85lb. to 95lb. per yard. The best practice as regards joints now is to lay the rails close together, allowing no space whatever for expansion and contraction. The theory is that the rail is so thoroughly protected by the pavement against changes of temperature so that there is very little necessity for making such an allowance. Occasionally, however, a small space is left between rails every 250ft. or 500ft. A great deal of wear at the joints has been obviated by thus butting the rail firmly together. Apart from this, however, the joints have been strengthened by the more general adoption of longer joint plates. Eight and twelve bolt joints, from 28in. to 36in. in length, are the best practice. Riveted and welded joints are also being tried.

Overhead Construction.—The general principles on which the best overhead material is made and the entire structure is erected are the following:

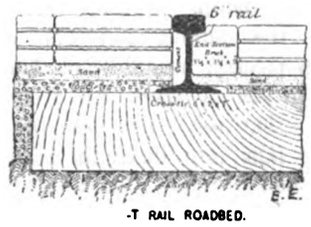
1. All hangers, switches, and other appliances connected with the trolley wire are supported by the span wires as near as possible at the line of the trolley wire. Originally, this support was several inches above the wire.

2. The bending or kinking of the trolley wire in appliances is avoided, together with any method of support which tends to put sharp and sudden bends in the wire in service.

3. The strains from service are taken by the metal parts of the appliances, not by the insulation.



Examples of Typical Roadbeds.



4. Frogs, cross-overs, circuit breakers, etc., are so constructed that the trolley runs over them smoothly, without being obliged to dip and return to wire, as was the case with some of the earlier appliances.

5. The materials used are strong and serviceable, the metal being usually of bronze, or, in the cheaper appliances, malleable iron, while insulation has been made which combines excellent insulating qualities with great resistance to breakage in any direction, or by sudden blows such as sometimes come from the trolley.

* Condensed from the *Street Railway Journal.*

Digitized by Google

6. The wires are so put up as to have several insulating points between trolley wire and ground, the first being usually the trolley-wire hanger itself, the second one or more strain insulators in the span wires, and the third the insulation of the pole tops by a wooden plug from the lower portions of the poles.

7. The curve construction is much less objectionable than was originally the case, owing to a better understanding of the different problems involved.

8. Almost all street railway systems of any size are sectionalised, so that trouble with the overhead system on one section will not interfere with the operation of cars upon all the others. The feeders leading to these sections are provided with fuses or circuit breakers at the station, so that a falling trolley wire will instantly break the circuit, and the wires from that section will become "dead" until the arrival of the emergency wagon. Moreover, in case of fire it is possible for the firemen to tear down the overhead structure and handle the wires thereafter without fear of shocks. This system of putting up the wires has done away with some of the most serious objections originally urged against the overhead electric system.

Generating Plant. – The tendency of the last few years has been towards direct-coupled plant and large units. In the early days, shafting, belts, and counter-shafting were everywhere employed. Now, although some belt-driven plants are still being manufactured, the bulk of the new sets are direct coupled. The table given on page 66 shows the practice of one of the large engine manufacturers in the matter of weights, speeds, diameter, weight of flywheels, etc.:

Referring to these large generators, the Walker Manufacturing Company, of Cleveland, O., have recently put upon the market an 800-kilowatt machine, of which some views are presented herewith. Two of these generators have been installed in the power station of the Detroit Railway Company, of Detroit, Mich. They are similar in design to the generators of the 400-kilowatt size built by the same company, so that a general description of the 800-kilowatt size will be typical of the other standard Walker Company's generators.

The magnet yoke is 13ft. 9in. in diameter by 28½in. wide, and is of cast iron. This material is considered by the makers to be superior to steel for this purpose, since, on account of the greater section required (the section being more than twice that of a steel yoke), a very much greater rigidity is obtained. The poles are 12 in number and are of soft iron, laminated and cast into the yoke. They have pole shoes of cast steel, which serve also to keep the magnet spools in position. The yoke ring rests upon broad feet at each side securely bolted to heavy cast-iron girder plates. These girders are extended to such distance that the yoke may be slid along in a direction parallel to the shaft sufficiently to be entirely clear of the armature, thus allowing complete accessibility to either the magnet coils or armature. The girders are laid in concrete and cement upon massive capstones, and are secured by heavy bolts passing down through the foundation.

The armatures are of the iron-clad type, 8ft. 10in. in diameter by 37in. in length, exclusive of commutator. Together with the commutator, it occupies a length of 45in. on the shaft. The plates are punched in segments from soft, well-annealed iron, and are secured by dovetailed projections fitted into corresponding slots milled in the rim of the spider. This detail is illustrated in the engravings, Figs. 3 to 6. The plates are held longitudinally by heavy end rings, the fastening bolts passing just inside of the laminated core. These end rings also serve as supports for the portion of the armature winding outside of the slots. An important detail of construction is shown in the engraving of the armature spider. It will be noticed that the rim of the spider is not made solid, but that the arms end in a sort of T-head. This is done to eliminate all danger of shrinkage strains, and it will be obvious to any engineer that this is a very simple and effective method of accomplishing the desired result. It is claimed to be superior to the old method of splitting the hub, and, furthermore, gives a better chance for more thorough ventilation of the armature core. The commutator spider is mounted upon a projection of the armature hub, and securely keyed thereto. The laminated core is divided into a number of sections separated by ½in. air-spaces, allowing an ample circulation of air.

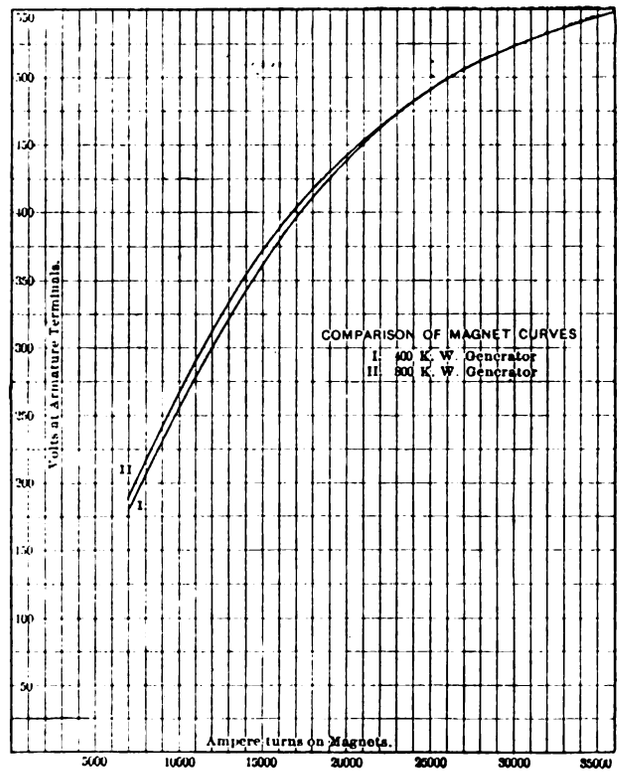

FIG. 2.—Characteristic Curves of the Large Dynamos.

The armature winding consists of flat copper ribbon formed into proper shape before being attached, and is entirely without joint except at the commutator leads. The coils are very thoroughly insulated in the manner illustrated in Fig. 1, and are held in place by phosphor-bronze bands.*

The construction of the commutator is shown in section in Fig. 5. The bars are held in place by a sectional clamp, so designed as to draw the bars firmly down on to the flat cylindrical surface of the spider. The leads are both riveted and soldered to the bars, and are made long and flexible. The diameter is 84in., and the active wearing face is 11in. The current density in the carbon brushes at full load is a little less than 35 amperes per square inch.

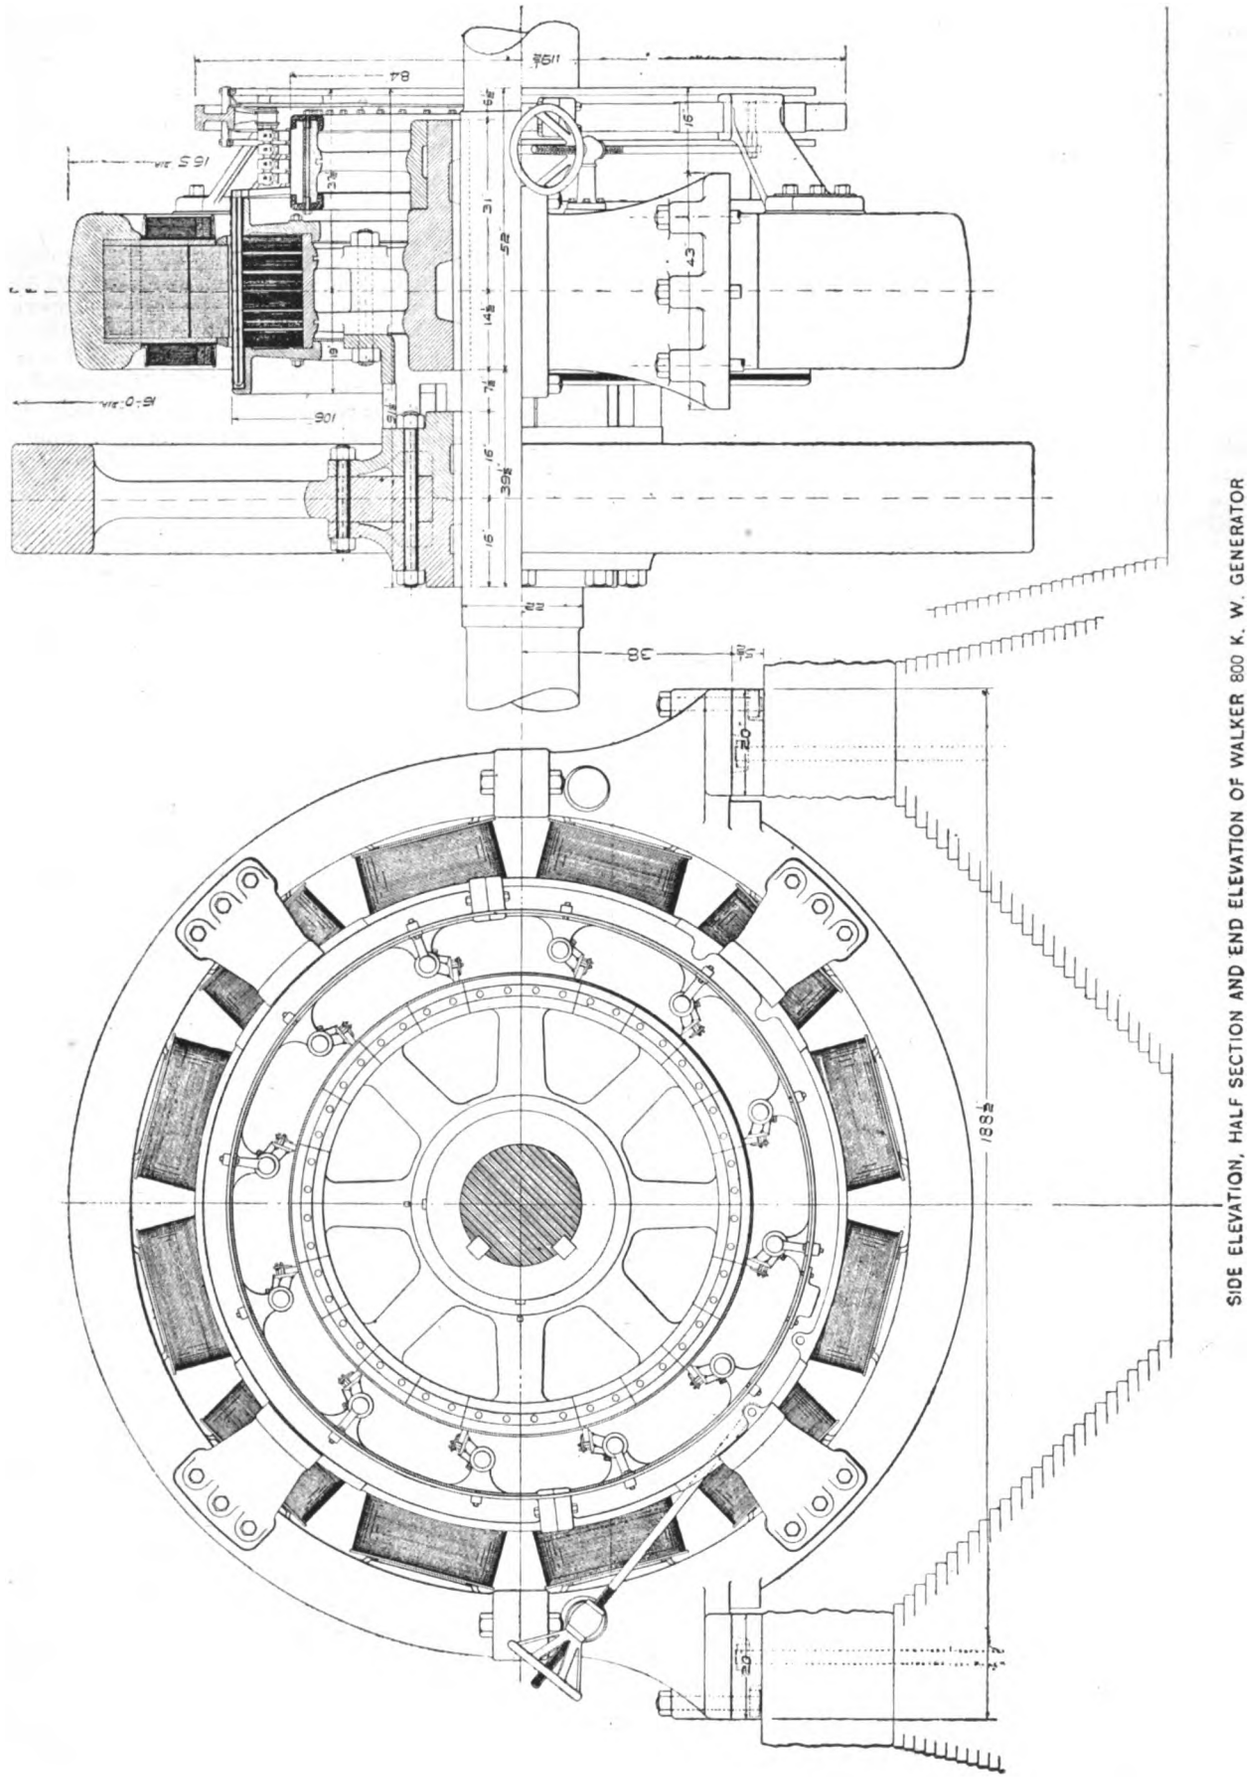
* As will be gathered from the description and the sectional view, the method of winding the armature is that of having two conductors in each slot, one abeve the other. The end connections can then be made of the cylinder type invented by Mr. C. E. L. Brown, of Baden, as described in our issue for August 16, 1895. In the above armature, however, the conductors are bent from one plane into the other at the engine end of the armature, and hence soldered joints only occur at the commutator. As seen in Fig. 1, each conductor consists of two parallel strips of copper.—ED. *E. E.*

Digitized by Google

The shaft is of forged steel, 22in. in diameter in the armature hub, and 19⅞in. in bearings.

The brush-holders are novel in design, in that the carbon is clamped solidly in the holder, giving the current a low-resistance path from brush to stud with no sliding contacts. The brush has a parallel movement, so that there is no rocking motion of the carbon when the commutator is slightly out of truth.

The general dimensions of the 400-kilowatt machine are as follow: outside diameter of yoke, 12ft. 2in.; diameter of armature, 90in.; diameter of commutator, 70in.; face of commutator, 8½in.



SIDE ELEVATION, HALF SECTION AND END ELEVATION OF WALKER 800 K. W. GENERATOR

FIGS. 3 AND 4.

It has been the aim of the manufacturers to produce a generator which should fulfil the exacting requirements of railway service with ease. Particular attention has been given to the details of mechanical design, and

Digitized by Google

the illustrations given of some of these details are intended to show how this has been effectively accomplished. These generators were designed for a constant voltage in the station of 550, and to divide the load as nearly as possible proportionally. The results have been gratifying to the manufacturers in all respects. The maximum variation of voltage at the switchboard is actually less than 2 per cent. under all variations of load. An inspection of the curves shown in Fig. 2 will show how perfectly the magnet characteristics of the two machines are matched, ensuring an almost absolute proportional division of the load between the various machines in operation.

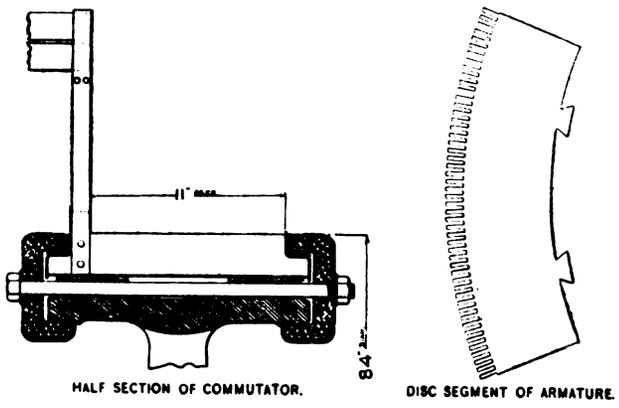


FIG. 5.

The full-load ampere rating of these generators is 730 amperes for the 400-kilowatt, and 1,460 amperes for the 800-kilowatt. With a continuous full load the temperature increase of the 400-kilowatt machine is 76deg. in the magnet coils and 73deg. in the armature. The increase of temperature in the 800-kilowatt generator is approximately the same under similar conditions.

A special study has been made of the question of non-sparking operation, and it has been the aim to so design these generators that without any brush shifting the non-sparking limit will be between 50 and 75 per cent. overload.

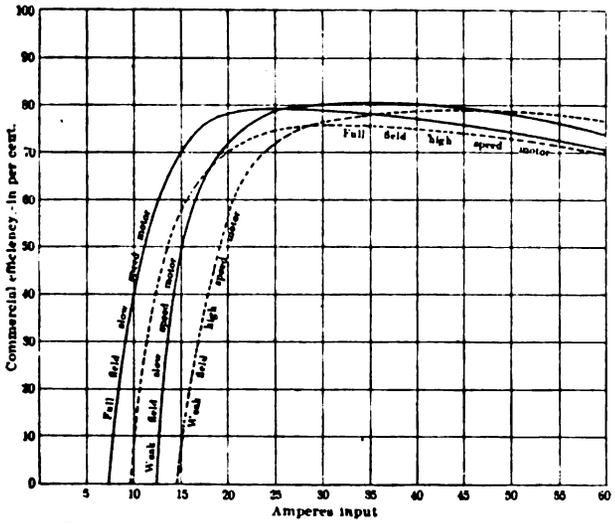

FIG. 7.—Efficiency Curves of a Street Railway Motor.

The practical operation of the generators has given results that are all that could be anticipated. As an illustration, it was necessary recently when two 400-kilowatt machines and one of the 800-kilowatt were carrying the load to shut down for a short time the 800, throwing the whole load, which happened to be 3,000 amperes, on to the two 400-kilowatt generators. They carried this overload of 100 per cent. for the time required without the least difficulty, and with only a slight sign of sparking, there being no shifting of the brushes. This illustration is given merely as an example of what these generators are able to stand up to in case of emergency. The commutators have taken on a dark, glossy surface, and in the case of the first generator installed the commutator has been running for about 60 days at the present writing without having been once dressed down with sandpaper. The others are behaving in the same manner.

The author then proceeds to describe most fully the modern street cars and motor trucks. The adjoining curves (Figs. 7 and 8), taken from a typical motor, are worthy of note. It will be seen that, although the efficiency curves hardly rise about 80 per cent., they are fairly flat for all loads about one-third of the maximum. The author, after reviewing the present state of conduit systems and cars carrying storage batteries, draws the following general conclusions in answer to the query, Will the overhead electric railway system ever be superseded by another and better system?:

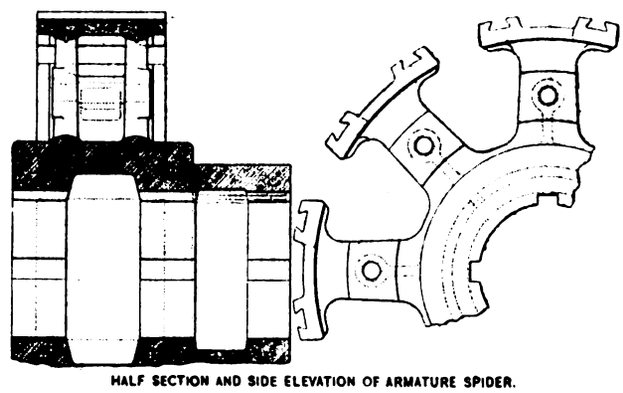

FIG. 6.

The ideal system is, of course, a self-propelled car carrying its own motive power, but compressed air, gas, ammonia, and steam have so far proved inadequate in power, or in other respects not adapted for street railway use, and almost nothing is, to-day, being done in that direction. One great difficulty in any system of this kind is that of providing sufficient motive power to always return a car to its source of supply, and in the complicated conditions of city street traffic a blockade is a serious affair indeed. Nevertheless, new applications of nature's forces, or new materials to work with, are constantly being brought out, and while it is extremely improbable that some entirely new form of motive power will be found

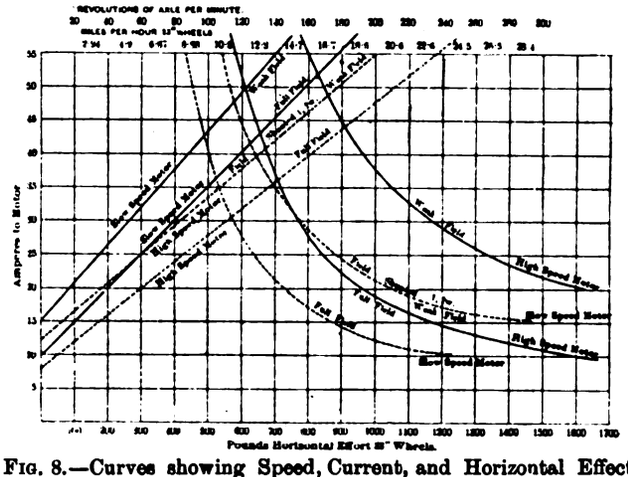

FIG. 8.—Curves showing Speed, Current, and Horizontal Effects of a Street Railway Motor.

peculiarly adapted to street-car propulsion, it cannot be said to be impossible.

The electric system, both overhead and underground, possesses certain intrinsic advantages which seem to make it in some respects the ideal system for street railroading. The first of these is found in the remarkable cheapness with which the motive power can be generated. In some of our large stations the entire cost of motive power for even a long double-truck car has been brought down to 6·25d. per car mile, and, under favourable conditions, to even 5d. per mile, this cost covering coal, water, station labour, lubricants, and repairs, and depreciation of station plant.

The motors are to-day far more efficient and mechanically perfect than formerly, as will be seen by the curves, and

it is doubtful if any materially greater efficiency can be obtained for a class of service which calls for such widely fluctuating amounts of power.

Altogether, therefore, the electric distribution for street railroads, considered from economic grounds, is not likely to be improved upon within its own lines of development, and the question then becomes, What particular method of distribution is to be final or best adapted to the purpose—the overhead system, the underground open or closed conduit system, or some other system yet to be devised?

This question can only be answered in a longer experience with both kinds of conduit work than is at present at our service. The overhead electric system has been tested under all conceivable circumstances, and has in every case proved itself adequate to the burdens placed upon it. It handles the heavy traffic of our principal city streets, it carries our people to their suburban homes, it pushes its way out into the country and increases land values, and in joining cities and towns on lines 20 or 30 miles in length it has proved so much more popular than parallel steam railroad lines as to seriously alarm railroad magnates and to cause their violent opposition to the spread of electric railroading.

COMMUTATORLESS DYNAMOS.

BY JAMES WHITCHER, A.I.E.E.

The *Journal* of the Institution of Electrical Engineers, May, 1895, gives an abstract of an article by Riccardo Malagoli in vol. i., 1895, of *L'Eclairage Electrique* on "An Alternating Rotary Magnetic Field and its Application."

There are statements in this abstract which call for criticism, but before discussing them the writer would say that he has not had an opportunity of referring to the original article, but he has no doubt that the abstracting has been as carefully and conscientiously done as usual.

The article deals geometrically with a subject of considerable interest in the theory of alternating currents, but there is certainly something wrong about the result. It is just as impossible to make a commutatorless direct-current dynamo in the way he suggests as in any other bar the one—the so-called unipolar method. The writer has reason to be positive about this, for he has put it to the test. About two years ago he became entangled in much the same line of thought, and he did not get clear of it again until practical experiment demonstrated conclusively to him the utter futility, not to say nonsense, of the idea.

It will bring the subject down from the clouds of vague theory and give it more practical interest to describe this experiment, but, in the first place, it is advisable to follow out the line of reasoning which seems to call for and justify the experiment. To keep a good practical colour on the discussion we will discard the idea of rotating vectors, and treat it only with reference to the "concretest" of electrical notions and apparatus. Thus, consider the piece of electromagnetic mechanism sketched in Fig. 1. It is a stationary Gramme ring, A, wound with a continuous circuit, having connections, B and C, brought out at opposite points on a diameter of the ring. Within the ring revolves the field magnet, D, with poles as marked. It is evident that the rotation of D will produce an alternating E.M.F. at the terminals, B and C, and that the characteristic curve of this E.M.F. will depend upon the arc covered by the pole-pieces of D. In the case shown the polar arcs are 120deg. each, and the curve will be like A in Fig. 2. This is the effect of a constant bipolar magnetic field rotating within a bipolar Gramme ring. Now, if the revolving magnet, D, be excited with an alternating current, the magnetic field will also alternate as it rotates.

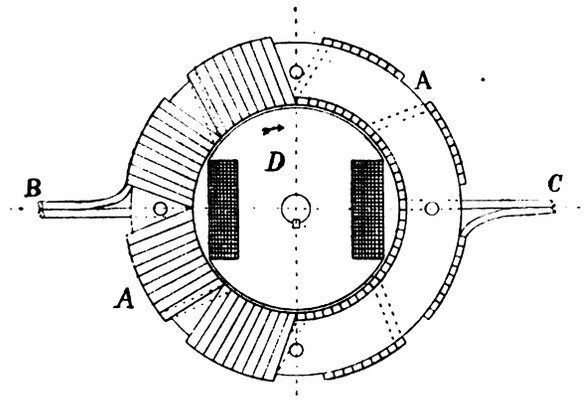

FIG. 1.

The effect this alternating rotary field will have on the windings of the stationary ring is very complex and difficult to analyse in a general way. But assuming that the period of the exciting current is equal to that of the revolution of the field magnet, and that the field is at its zero values when the polar axis is on the diameter, B C, the case is much simpler. It happens, then, that the rotating field is always of one sign on one half of the ring, and the opposite sign on the other.

Probably more often than any other has this circumstance been seized on, in some guise or other, as a fancied solution of the commutatorless-dynamo problem. At first sight it does look as though the current in the ring windings must at least be unidirectional, though it may be pulsational. However, it is not so. Analysed by means of the calculus, it is quickly seen that the actual effect is to produce an alternating current of double the frequency of the exciting current. It is not easy to work it out otherwise; but remembering that the alternating field has what may be called a "transformer" action as well as a "dynamo" action on the ring windings, we can approach this result nearly enough to realise its truth. For following out the "transformer" action alone, it is seen that it will give two maximum values of E.M.F. per revolution both of the same sign, and occurring when the polar axis is on the diameter B C; and the "dynamo" action is seen to give also two maxima of like sign, but opposite to the two former, and occurring when the polar axis is at right angles to B C; and the zero values of either action concur with the maximum values of the other: hence the E.M.F. will alternate twice per revolution of the field, and its curve may be

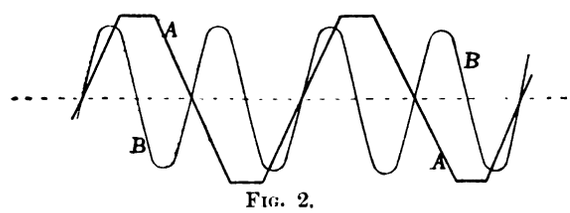

FIG. 2.

Digitized by Google

represented by B of Fig. 2. If all the variables involved were simple sine values, this curve would be a symmetrical sine curve also.

From the foregoing it is clear that a *bipolar* alternating rotary magnetic field applied to a stationary bipolar Gramme ring will not produce a continuous current. However, it is not a bipolar field that is actually understood in this paper of R. Malagoli's, but rather a multipolar field, or equivalent to one having an infinite number of poles. It is necessary, therefore, to pursue the investigation further, what has preceded being a helpful preliminary. If the rotating magnet be as nearly as possible a complete drum of laminated iron with quadripolar winding, as in Fig. 3, and the adjacent poles be excited with alternating currents of 90deg. difference in phase, while the drum rotates once per period of alternation, the field produced will be a near equivalent of the one of infinite poles required. The resultant effect of the two-phased exciting currents is to produce poles of the given maximum strength successively on every diameter of the drum. We can, therefore suppose each diameter to be the axis of an alternating magnet. Every one of these diametral magnets will have its strength nil when on the diameter B C, and maximum when on the diameter E F at right angles to B C.

Examining the magnetic condition of the ring produced by such a rotary alternating field, it appears that it is perfectly quiescent and constant, both as regards sign and strength. On the one half is a north pole, on the other a south; the diameter E F being the axis of these poles and

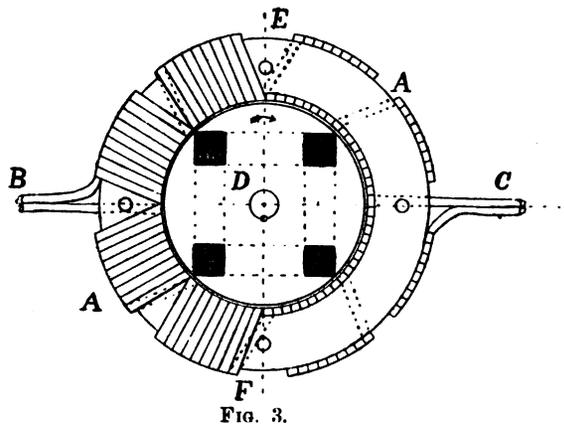

FIG. 3.

the position of maximum strength of field. Here is exactly what is described by our Continental author, and it will be observed that the same magnetic state of the ring could be produced by stationary poles of constant strength. This fact is in itself ominous to the otherwise very plausible deduction that a rotary field of this kind will generate a continuous current in the windings of the ring, but it does not dispose of it.

The field produced by stationary poles could, of course, have no possible effect upon the stationary conductors, but this does not prove that a field outwardly the same, but created by a number of rotating and alternating poles, must be equally ineffective. Actually it is so, but it was this same question that led the writer to make the experiments described later. Yet it is possible to prove the point without experiment; and though it may seem vague and involved the proof is quite admissible, for its rigid accuracy cannot be shown without introducing mathematics.

The proof lies in the fact that the multipolar alternating rotary magnetic field in question may be considered as a combination of a number of bipolar fields, such as the one treated of in the first instance. As we have already seen, under certain conditions a four-pole field is its practical equivalent; and this is the same as a combination of two similar bipolar fields, the one rotating and alternating 90deg. behind the other, in position and phase respectively. It has been shown that the effect of either of these bipolar fields separately is to create an alternating current of double the frequency of the field. Now, if the two effects be added together with due regard to their phase, it appears that they neutralise each other very nearly, if not absolutely. The writer believes that the neutralisation is absolute and complete for every condition, but in any case, if it be not, the result would still be an alternating E.M.F. at the terminals B and C, and not a continuous one. In short, the apparatus is as far off being a solution of this problem of a commutatorless dynamo as it could well be. And seeing that it is only in accordance with certain irresistible mathematical laws that the problem can have no practical solution, this is little to be wondered at.

It was with very little confidence of a successful issue, but rather to settle a doubt of the mathematical edicts raised by noticing how strong was the belief among electrical engineers that the thing was still to be done, that the writer made the following attempt at it. A model was made as shown in cross-section at Fig. 4. Here A A is a carcase of laminated iron built up of stampings ·025in. gauge to about 2in. thick. In the spaces at B and C are exciting coils, the carcase being cut across to permit these coils to be slipped on. The curved portions of the carcase, both upper and lower, are wound closely with one layer of insulated wire, and the four ends brought out to terminals. In effect this is a Gramme ring with the addition of exciting coils. Within the bore, which is 4in. diameter, revolves the drum, G. This also is laminated iron, and it is deeply slotted, so as to present a number of well-defined teeth revolving as closely as possible to the windings, E and F. The action contemplated was as follows: The coils, B and C, were excited by a constant current from a separate source, in a way to produce a north pole, say, at the top half of the carcase and a south pole at the bottom half. The

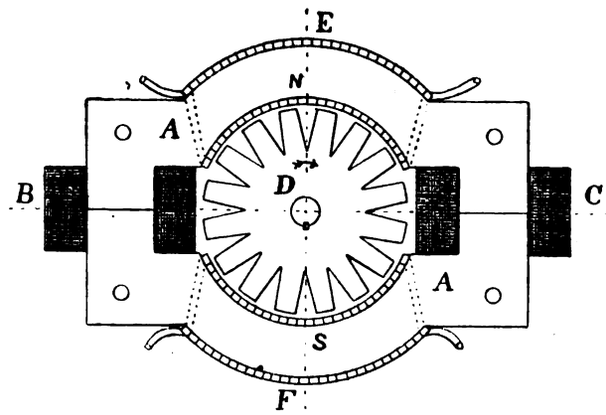

FIG. 4

magnetic circuit was thus completed through the drum, and inner portions of the windings, E F, were immersed in a strong but quiescent magnetic field. The revolving teeth of the drum were to be the means of rotating this field while not reversing the poles of the stationary ring or carcase; for it is clear that each tooth forms an alternating pole whose sign changes as it rotates across the neutral line, B C. The gaps, or slots, in the drum were intended to prevent slipping back of the field against the rotation.

This machine was designed to give 100 volts and a considerable current when run at a moderate speed. Hence it cannot be said that the test was vitiated by restriction of size of the apparatus. The result was negative enough to convince the most sanguine of sanguine inventors. Not a vestige of continuous current, nor apparently of alternating current, was to be detected in the whole or any part of the windings, E and F. This satisfied; but, with a view to completing the answer, the machine was modified, so that the drum might be partially excited by actual alternating currents in windings revolving with it. For this purpose a few turns of stout wire were wound across the drum in each opposite pair of slots and close-circuited. With the drum revolving as before, alternating currents were generated in these closed circuits, and excited a transverse field having south pole, say, at B, and north pole at C. This transverse field, at any rate, would be a "rotary alternating field"; but tests applied to all likely portions of the windings, E and F, within its influence showed no indication whatever of current.

One's small wavering doubt could not withstand so emphatic an overthrow as this, and, of course, it was annihilated, and with it all charm for him of the great will-o'-the-wisp of the electrical engineer.

INSTITUTION OF ELECTRICAL ENGINEERS, Jan. 16.

At last night's meeting of the Institution the following candidates were balloted for:

Foreign Members.—Charles M. Hall, Pittsburgh Reduction Company, Pittsburgh, Pa.; Christian Vilhelm Kursch, Great Northern Telegraph Company, Libau, Russia; Felix J. L. Mélotte, Quay du Canal 23, Herstal lez Liège, Belgique; Louis de la Pena y Brana, San Roque 8, Madrid, Spain; C. Poulsen, Imperial Chinese Government Telegraphs, Tientsin, China.

Member.—A. M. Billington, London Electric Supply Corporation, Deptford.

Associates.—Frederic J. Anson, 6, Lombard-street, London, E.C.; Henry Carr, Messrs. J. F. Baddeley, St. Petersburg; Arthur Dalby Chamen, "Horton," Mornington-road, Woodford Green; Henry Coles, 10, Arcade, High-street, Swansea; Thomas Davis, 20, Alexander-road-hill, Southampton; Herbert R. Harper, 7, Carden-road, Peckham Rye, S.E.; Thomas Edward Ingoldby, 12, Montague-street, Russell-square, W.C.; Leopold Lucas, 55, Oxford-gardens, Hyde Park, W.; William Maurice, Swanwich Collieries, Alfreton; William Bourchier Nicholson, 1A, Acre-lane, Brixton, S.W.; John Francis Pawsey, 1, Queen's-place, Cork, Ireland; John Horace Reeves, M.A., 85, Eltham-road, Lee, S.E.; Arthur Dudley Southam, 29, Paternoster-row, London, E.C.; James William Speight, 2, Views Grange, Allerton, Bradford; William Edwin Toll, Grove House, Surbiton, Surrey.

Students.—Ernest Bernstein, 29, Red Lion-square, W.C.; John Muir Donaldson, 80, Wellesley-road, Croydon; George L. Eynon, Messrs. J. C. Lyell and Co., 55, Victoria-street, S.W.; Charles C. Garrard, 32, Shrubland-road, Dalston, London, N.E.; Frank Graham, 12, Ladbroke-gardens, Notting Hill, W.; Selwyn Seafield Grant, Central Institution, Exhibition-road, S.W.; E. B. Gray, Perces, Halstead, Essex; Walter Hall, 83, Digby-road, Green Lanes, N.; Leopold H. Harris, 77, Sutherland-avenue, London, W.; T. A. Kerr, 22, Artesian-road, Bayswater, W.; Arnold G. Livesay, 33, St. Charles-square, North Kensington, W.; Edgar Walford Marchant, Central Institution, Exhibition-road, S.W.; H. R. Mott, Hillcrest, Elmbourne-road, Upper Tooting, S.W.; Harry Charles Weston, 80, Chancery-lane, E.C.; Harry George Whiting, 2, Aubrey-road, Crouch End; Arthur Stanley Williams, 288, Uxbridge-road, Ealing Dean, W.

After the premiums had been awarded, **Major-General Webber** proposed a vote of thanks to the retiring president (Mr. R. E. B. Crompton), which was duly seconded and carried.

Dr. Hopkinson, before proceeding with his presidential address, said recent events had made unpleasant revelations to many of them, and had shown them that there were certain peoples who would regard with satisfaction any misfortune that might befall this country either through any international dispute or any little error committed by our countrymen which might involve us in quarrels with those who were formerly our friends. Foreign nations aimed at providing for their safety in these contingencies by a system of compulsory military service, but in England, where we did without that, surely it was the duty of each one of them to consider what he could do towards providing for the safety of his country. Many of them in that Institution possessed aptitudes which might be of great use in the event of war, particularly in regard to their knowledge of electricity and its use for military telegraphs, search-lights, training of guns, submarine mines, etc. He knew that anything they could do would be heartily welcomed by the authorities at the War Office. He had written, among others, to Lord Kelvin, asking him what he thought of the idea, and he had replied cordially approving of the movement, and saying that he hoped and expected valuable results. The Council had that evening passed a resolution "that steps should be taken to render available for the purposes of national defence the technical skill and knowledge of electrical engineers." A committee had been formed consisting of the following: the President, Major-General Webber, Mr. Crompton, Mr. Edmunds, Sir Frederick Abel, Mr. Mavor, and Mr. Erskine. Probably that committee would first of all ascertain what members of the Institution were willing to serve and what time they could give to training. It would also ascertain what places wanted filling in certain corps, and appoint the right men to fill those places, and if there were more men than vacancies, more corps might be formed. If each of them would do his duty according to his opportunities, they would succeed in rendering valuable services to their country.

Mr. Erskine said he was sure a great many of them were in sympathy with the proposal, and could work in one way or another.

It was decided by a show of hands not to discuss the matter further at present.

Dr. Hopkinson then delivered his presidential address as follows:

INAUGURAL ADDRESS BY DR. JOHN HOPKINSON, M.A., F.R.S., PRESIDENT.

When it was suddenly proposed to me that I should a second time be your president, I felt considerable reluctance to accept the duty. This reluctance arose from two causes. Of the first I am ashamed—pure laziness—and of it the less I say the better. The second was a *bonâ fide* doubt as to whether I was specially suitable for the post. But it soon struck me that that was a matter for which those who proposed me were responsible, and not I who accepted, but had not sought the office. But, if I felt a temporary reluctance, do not suppose that I for a moment failed to appreciate the honour which had been done me. To be called by his fellow professional men to fill the chair which has been occupied by men of such distinction as Kelvin, Siemens, Abel, Crookes, not to mention others, is an honour of which anyone may confess himself proud. After once having occupied this chair, to be called to it a second time is a greater honour, for it shows that one's efforts, however imperfect, have been generously appreciated by those for whom they were made. I thank you for the honour, and assure you I will do my best to verify, if I can, the judgment of those who proposed and you who elected me, rather than my own misgivings.

The century which is now just drawing to a close has been a time remarkable above all other times for the extraordinary development of our knowledge of the physical sciences, and in particular of experimental physics and chemistry, and for the extent of the practical application of this knowledge to useful purposes. The century has seen the discovery of the mechanical nature of heat, of the spectroscope, and of the whole of the science of organic chemistry; it has seen the enormous development of the application of the steam-engine, the construction of our railway system, and the supersession of sailing vessels by steamboats. But perhaps the most remarkable illustration of this development is to be found in the science, and its application, with which this Institution has to deal. Consider what was known of the sciences of electricity and magnetism at the end of the last century. The two sciences were then quite unconnected. In magnetism the properties of permanent magnets were known—that is to say, it was known that steel needles could be rendered magnetic by rubbing with a loadstone, and that when so rendered magnetic they would tend to remain in that condition; it was known that if a magnet were broken in parts, that each part would exhibit north and south poles like the magnet from which it was broken; it was also known that the earth exhibited properties of magnetism, inasmuch as a magnetic needle free to move would point, on the whole, to the north; broadly speaking, what we know to-day about permanent magnets was known, and that was about all. The practical applications were limited to the use of a magnetic needle in the mariner's compass. The knowledge of electricity was confined to what is now known as electrostatics. That certain bodies when rubbed exhibited peculiar properties, attracting and repelling each other, had long been observed; and the facts expressed by the hypothesis of positive and negative electricity were known—namely, that two pieces of amber which had been rubbed repelled each other, two pieces of glass which had been rubbed repelled each other, but a piece of rubbed glass and a piece of rubbed amber attracted each other. In a general way the properties of conductors, as distinguished from insulators, were also known in their relation to charges of frictional electricity. Cavendish had made elaborate investigations into the capacity of condensers, the condensers being usually of glass, and being charged by the old-fashioned frictional means. Franklin had proved the identity of the cause of lightning with the cause of the sparks produced by frictional electricity. Just 100 years ago Galvani had made his celebrated experiments showing that the muscles of the limb of a frog were disturbed by contact with a piece of copper and a piece of zinc which touched each other; and that was the only fact which up to that time had ever been observed in the enormous group of facts which now constitute our knowledge of the production of electricity by chemical action. Shortly stated, that was the extent of our theoretical and experimental knowledge of electricity. The practical applications of this knowledge were almost nil. I can recall nothing excepting the provision of lightning conductors as a protection to buildings.

It is worth insisting that the additions to our knowledge of the properties of permanent magnets and of frictional electricity during the century have not been of great importance, and the practical applications of these limited branches of knowledge have been few. If one is asked what uses can be made of our knowledge of frictional electricity apart from the phenomena of currents, it is hard to name anything of importance. In like manner, in regard to our knowledge of permanent magnets, it may almost be said that the advances in practical applications have been confined to improvements in the use of the mariner's compass, which, most important although they are, have had comparatively little share in the changes in our conditions which the last hundred years have witnessed. Almost everything in the way of practical applications of electrical science has been the outcome of subsequent discoveries—the voltaic cell discovered by Volta in the year 1800; Davy's discoveries in electrolysis, Oersted's discovery of the action of currents upon magnets, Ampère's discoveries of the mechanical action of currents upon currents, and Faraday's discoveries in electromagnetism, not to mention the names of eminent men still living. Now, the remarkable thing is that none of these phenomena had ever been witnessed by mortal man. It was not that they were constantly occurring around us, and that the explanation had not been seen; it is the fact that the phenomena had never been experienced. It would seem that the phenomena of electric currents as Volta dis-

Digitized by Google

covered them do not occur in nature on any substantial scale. Electromagnets may be regarded as purely a creation of the human mind; so far as we know at present no example of an electromagnet is found in the natural world. The great currents produced by the action of electromagnets have, so far as we know, no counterpart in nature—not only no counterpart in degree, but none in kind. In this respect our science differs much from many others. In mechanics and in heat we may find the phenomenon of which we make use occurring without our aid on an enormously greater scale than we are accustomed to use; changes are constantly occurring around us, and it is conceivable that we might have obtained much of our present knowledge by the aid of observation without experiments. But it is not so with electricity and magnetism. We should be puzzled even now to adequately illustrate the facts we know by observation alone without experiment.

Let us consider for a moment the practical applications which have been made of electrical knowledge during the last 60 years. The first, of course, is the telegraph. What are the scientific facts which have been used in the development of telegraphy? The currents are generated either by chemical means or electromagnetic means. The receiving instruments either depend for their action on the action of currents upon magnets, or, in a limited number of cases, on electro-chemical decomposition. We might put it broadly thus—that, with the exception of the distinction between conductors and non-conductors and certain properties of condensers, the telegraph could do without anything that was known up to the end of the last century, and that it wholly depends upon more recent discoveries. Much the same may be said with regard to the more recent applications—the electric light, electric transmission of power, and the rapidly growing department of electro-chemistry—may all be said to be quite independent of any facts which were known before the year 1800, and entirely based upon discoveries made since. Suppose it were a fact that electricity could not be produced by friction, that we knew nothing concerning the attraction which oppositely electrified bodies have for each other, that permanent magnets did not exist—or, in other words, that iron had no hysteresis—would it make any material difference, so far as we know, in the practical applications of electrical science to telegraphy, telephony, electric light, electric transmission of power, or electro-chemistry? The permanent magnets, which are practically used only in instruments, would be at once replaced by electromagnets, and the apparatus would work just as it does now.

Enough has been said, I think, to show that the knowledge of electricity and magnetism which was possessed by men at the end of the last century, intensely interesting though it was, has not been the parent of the great applications of later days; that the knowledge of the last century has not grown in any great degree upon the lines which existed at its commencement, but that our advances in science, as in practice, were the result of the discoveries which were made since the beginning of the present century.

It has been a frequent practice with presidents of societies devoted to promoting some department of science, theoretic or applied, to deal with the history of the science in their presidential addresses—to show how one idea has led up to another, and how marked have been the advances made. This evening I propose to adopt a different course. What I wish to consider is, how would the theory of electricity have been arranged if the order of discovery of the facts of the science had been other than it has been? Here I owe you some words of apology. You are a practical body more immediately interested in the application of science to the service of man than in the promotion of abstract knowledge. The justification I would offer for my subject is that the science of electricity, whether viewed from the practical or theoretical side, is in a state of extraordinarily rapid advance. The rules of practice of yesterday are of little use to-day, hence more discussion is needed, more publication is needed, than in departments which are in a more stable state. Furthermore, there is no department of applied science in which the connection with theory is so close and intimate. The practical electrical engineer reads eagerly the results of those who, careless whether their work finds application or not, labour to advance knowledge; he attacks these results whether they be expressed in the ordinary speech of men or in mathematical symbols. On the other hand, much of our knowledge of electricity, viewed from the scientific side, has come from those who are concerned with practical application. Nowhere else do we find a closer interdependence of pure science and practice. In what I have to say there will be much that is trite and obvious to the merest tyro in electricity. What I wish to do is to show how the facts of electrostatics can be explained by the facts of current electricity without hypothesis; and it is necessary to rehearse elementary principles. In a complicated subject like electricity, in which the appeals to our senses are indirect, there are open to us many ways of arranging our ideas, any one of which will give us a consistent account of that which we observe. We may take as our fundamental basis one or other of various groups of facts, and deduce others therefrom. The actual arrangement of ideas on the subject depends in a measure upon the accident of the historical order of discovery. Thus, the fact that actions at a distance between electrified bodies were known many years before the phenomena of current electricity and electromagnetism is the reason why that part of the science which treats of such actions is to-day treated first and made the basis of the rest. The time has, I think, come when we may with advantage reconsider our position, and see whether or not our ideas may be more conveniently arranged. The arrangement which is most convenient may no doubt depend upon the phenomena which occupy the most prominent place in the practical use we wish to make of the science. Those facts are best treated as fundamental which are most frequently used, provided they are sufficiently simple. To the practical electrician are the facts of current-electricity or of the attractions and repulsions of electrified bodies more familiar? Surely the transference of energy by current is the agent by which almost every operation he purposes is effected, whilst the phenomena of electrostatics touch him only at points in the theory of electrometers, and so forth.

I propose, then, this evening to sketch out briefly, *ab initio*, how we may base the science of electrostatics upon the theory of current-electricity taken as fundamental. We might, if we pleased, drop the word "current" altogether and substitute another. It seems hardly worth while, but I shall ask you to bear in mind that, if used to-night, it does not connote the idea of anything flowing along the conductor. It is a name for a directed magnitude, and nothing more. I shall have occasion to refer to some elementary experiments, but you will bear with me, I trust, for we are concerned with arranging the subject on as small a basis of facts as is consistent with rigid deduction. Please, then, to banish from your minds all theory on the subject, and let us imagine that the facts of current-electricity are first discovered, and that it is only when these are well developed that electrostatic attractions and repulsions are found out.

In a vessel of dilute sulphuric acid is placed a piece of pure zinc, or of zinc carefully amalgamated, and also a piece of copper, platinum, silver, or carbon, the two plates not being in contact with each other. It is observed that no change takes place; the acid does not attack either plate. The two plates are now touched with the two ends of a wire of copper or other metal; immediately the zinc begins to dissolve in the sulphuric acid, and gas—which, if collected, proves to be hydrogen—is found on the copper or platinum plate. If the plates are large and near together, and the wire is not too long or thick, it becomes very sensibly heated. On separating the wire from either plate, the chemical reaction and the heating of the wire cease. When the wire touches both plates there is then development of chemical energy in the vessel of acid; but a part of this energy appears as heat, not where it is developed, but in the wire connecting the plates. Whether this energy goes across the space of air between the zinc plate and the wire, or whether it goes along the wire, we do not know; but that the two plates should be rendered continuous with each other by a wire or some equivalent is a condition precedent to the chemical reaction and to the heating of the wire.

Let two such vessels of dilute acid, with plates of zinc and copper, be provided, and let the copper in one vessel be connected metallically to the zinc in the other; nothing happens until the copper in the second vessel is connected to the zinc of the first; then both zincs are dissolved, hydrogen is liberated on both copper plates, and the connecting wires are more or less heated.

Again, varying the experiment, let the coppers in the two vessels be connected together and the zincs be connected together: no reaction or heating occurs.

The combination of a piece of zinc and a piece of copper dipping separately into a vessel of dilute acid is called a "galvanic cell," or element; a series of elements connected together, copper to zinc, is called a "galvanic battery." Galvanic elements and batteries take a multitude of forms: the zinc may be replaced by another metal—for example, cadmium—and the copper by platinum; many other liquids than dilute sulphuric acid may be used; but all galvanic batteries have this in common—to cause them to work, the chain or circuit must be completed by a wire touching the zinc at one end of the series and the copper at the other, and then chemical reactions occur in the cells, and heat is liberated in the metal connections. The zinc and copper plates, or their equivalents, at the ends of a galvanic battery are called "poles."

(To be continued.)

A vote of thanks was proposed to Dr. Hopkinson for his interesting discourse, which was seconded and carried unanimously.

The next meeting will be held on Thursday next, the 23rd inst., when the discussion on the papers recently read by Mr. F. Bathurst on "The Electric Wiring Question," and Mr. Sam. Mavor on "Concentric Wiring," will be resumed. These papers were given in our issues of November 29 and December 13, 1895.

TO CORRESPONDENTS.

All Rights Reserved. Secretaries and Managers of Companies are invited to furnish Notice of Meetings, Issue of New Shares, Installations, Contracts, and any information connected with Electrical Engineering which may be interesting to our readers. Inventors are informed that any account of their inventions submitted to us will receive our best consideration.

All communications intended for the Editor should be addressed C. H. W. Biggs, *139-140, Salisbury Court, Fleet Street, London, E.C. Anonymous communications will not be noticed.*

TO ADVERTISERS.

Advertisements should be addressed to the Publisher, 139-140, Salisbury Court, Fleet Street, E.C., and should reach him not later than noon of Thursday. **Special Terms** *for a series can be arranged on application.*

"SITUATIONS VACANT" and "WANT PLACES" Advertisements will be charged at THREE WORDS for ONE PENNY with a MINIMUM charge of SIXPENCE.

TO SUBSCRIBERS.

"The Electrical Engineer" *can be had by Order, from any Newsagent in Town or Country, and at the various Railway Stations; or it can, if preferred, be supplied direct from the Office on the following terms:*

	3 months.	6 months.	12 months.
United Kingdom	3s. 3d.	6s. 6d.	13s. 0d.
Other Places	4s. 11d.	9s. 9d.	19s. 6d.

(Post Free, Payable in Advance.)

Cheques, Post Office and Postal Orders for Subscription and Advertisements should be made payable to C. H. W. Biggs, *139-140, Salisbury Court, Fleet Street, London, and be crossed "Union Bank."*

BOUND VOLUMES.

Vol. XV. of new series of "The Electrical Engineer" *can be had bound in blue cloth, gilt lettered, price 8s. 6d. Subscribers can have their own copies bound for 2s. 6d., or covers for binding can be obtained, price 2s.*

MOTORS IN FACTORIES.

It has taken at least ten years for some of our foremost electrical manufacturers to discover that there will be a gold mine in the coming use of motors. We do not mean the use of motors for traction purposes, but for factory work. For many years past we have contended that in many instances the use of electric motors would be more economical than the use of gas or steam. Our contention is being rapidly proved to be correct. It may be said at once that we should not pit the electric motor against steam when the load was constant: only in the case of factories with a large number of machines thrown periodically in and out of gear and run by belting from countershafting. Mr. Crompton discusses this question in the current number of *Cassier's Magazine*, which number, by the by, is devoted entirely to electrical matters. We shall quote somewhat largely from Mr. Crompton's article, but before doing so must call attention to the work of a gentleman whose name has lately been very much in evidence. Whatever be the claims of Sir David Salomons to our consideration, there is one which will be freely granted. He has spent large sums of money and given largely of his time to prove his opinions that electrical energy gives us the best artificial light and the best motor power for machines used intermittently. He many years ago fitted his estate workshops with motors, and demonstrated both their economy and feasibility in working. Some eight or nine years ago a canvass was made of a certain part of London, but no English firm would undertake the distribution of power in that district without guarantees which could not be forthcoming. Yet when the subject came to the ears of American financiers, they professed themselves willing to carry out the work. The promoters of the scheme, however, did not care to work in this direction, and the matter fell through. During the past eight years hundreds of horse-power have been changed from steam to gas, and there would, therefore, be in this particular district less support now than was possible eight years ago.

But in other places matters have not advanced so rapidly. Users of steam power had to be convinced that steam could be replaced, and such conviction could not be obtained by isolated instances of success. It was left for electrical manufacturers to show their confidence in their own work by installing motors in their own shops. This some of them have done, and the installations have proved singularly economical. Abroad, one or two well-known factories, where steam must otherwise have been used, are trusting entirely to motors, such as the small-arms factory at Hersthal and, again, at Lugansk, while in many other cases, with water power available, electrical apparatus only has been installed. England, as usual in some electrical things, has in this watched and waited, but the engineers, having now satisfied themselves as to the efficacy of the apparatus, will no doubt push their wares with vigour and success.

Mr. Crompton, in his article discussing the figures of Prof. Kennedy, says: "Although Prof. Kennedy, the president of the Institution of Mechanical Engi-

Digitized by Google

neers in England, in his address to that institution in April, 1894, considered that in a factory, with the useful work taken at 100, the total indicated horse-power of the steam-engines may be taken at 145, the author finds that this proportion is far too favourable, and is true only in the case of a limited number of establishments where the load is steady throughout the working day. In most cases the following figures more closely represent the actual state of affairs:

Average useful work	100
Average wasted in belts and shafting	75
Average wasted in engine friction	60
Total average indicated horse-power	235

"If the author's assumption is approximately correct—and he believes it to be so in the majority of cases in works such as we are now considering—and if we apply it to a factory which requires an average of 500 h.p. net delivered at the tools, we find that the average indicated horse-power which probably would be spread over three steam-engines would be 1,175. We find, however, that in order to work this plant for 2,950 hours per annum, taking coal at 12s. per ton, the coal bill would work out at £2,260; the probable wages bill, £1,480; the stores, £600; and the repairs and depreciation of plant together, £1,600; making a total cost per annum of £6,000 for 500 net horse-power delivered at the tools, or at the rate of £12 per annum per horse-power. Now, what can we promise by substituting for this arrangement a modern electrical equipment? In the first place, although we should still divide our total power between three engines, we do so only in order to avoid the risks of a break-down affecting the whole establishment. We should make these three engines identical in form and size, and we should place them together, so that they could be worked by one attendant. We can claim for modern generating plant that it can be made with certainty to specification to produce the electrical horse-power delivered at the terminals of the various motors, distributed all over the works within a radius of 500 yards, with a consumption of 2½lb. of coal per hour; and it is easy to show from the actual records of Messrs. Siemens, Messrs. Crompton, and others that the proportion of useful work done at the tools may bear to the average indicated horse-power of the engines the high proportion of 500 : 680, so that the total coal bill in this case would be only £1,080; wages, £375; stores, £260; repairs and depreciation, £1,300; making a total per annum of £3,000, or £6 per annum per net horse-power, which is exactly half the cost of the older system. It will be seen that a very large share of the above saving is on the labour bill, and that, consequently, in the cases where fuel is exceptionally cheap, the saving would be diminished; but even if we take fuel at the extremely low price of 6s. per ton, the correction in the above figures would be only such as to reduce the cost of the older system to £10 per annum per net horse-power, and in the case of electric transmission to £5. In this case, too, it is here shown the saving effected may be £2,500 per annum."

We can only hope that these figures of Mr. Crompton, substantiated, as he tells us they are, by his own experiments and those of Messrs. Siemens, will assist in causing greater examination to be made by consulting architects and engineers into the question of fitting up factories with motors. There is one great point to be insisted upon. Competition has nowadays cut manufacturers' profits down to a very low point in many directions. Where new works are being built it is the interest of the proprietors to arrange everything for the most economical production, and if the geographical position is right the newly-equipped mills ought always to have the pull over older concerns, in that the machinery employed ought to be more efficient. Thus, a great impetus to electrical work ought to come from the directions named—architects and consulting engineers who are called upon to design the new works.

WHAT, WHEN, AND WHERE.

Physical Society.

January 24, 5 p.m.—At Burlington House. 1. Exhibition of geometrical instruments by E. Scott and Signor Monticolo. 2. "Resultant Tones," by Prof. J. D. Everett. 3. "Experiments with Incandescent Lamps," by Sir D. Salomons.

Institution of Civil Engineers.

January 17, 8 p.m.—At Great George-street, Westminster, S.W. Students' meeting. "Iron Tunnels," by W. O. Leitch, jun.
January 21, 8 p.m.—Discussion on the Hon. R. C. Parsons's paper on "The Sewerage Works of Buenos Ayres."

Royal Institution.

January 17, 8 p.m.—At Albemarle-street. Weekly meeting. "More about Argon," by Lord Rayleigh.

Society of Arts.

January 20, 8 p.m.—At John-street, Adelphi. Cantor lecture, "Alternate-Current Transformers," by Dr. J. A. Fleming, F.R.S.
January 22, 8 p.m.—Ordinary meeting. "Supply of Sea-Water to London," by F. W. Grierson.

North-East Coast Institution of Engineers.

January 17, 7.30 p.m.—At the Literary and Philosophical Society, Newcastle on-Tyne. "Counter Sinking in the Shipyard," by R. H. Muir.

THE ARC LIGHT.*

BY PROF. SILVANUS P. THOMPSON, D.SC., F.R.S.

LECTURE II.

(Continued from page 49.)

ENERGY SPENT IN THE ARC.

Before passing away from the relations established above let us pause for a moment to consider the energy question. You may sometimes find it said, and it is perfectly true when you are dealing with a fixed resistance, that the energy spent by a current is proportional to the square of the current. That is, in fact, Joule's well-known law. If you double the current through a given resistance, the amount of energy you have to spend is fourfold; and if you were heating carbon you would perhaps argue that the light would be fourfold. But here we are confronted with the fact that, whatever the law might be supposed to be, when the current is doubled the light is doubled, not quadrupled. The light does not go by the square of the current. There is no paradox or puzzle in the circumstance, if one has once realised that important point developed in the former lecture that the resistance of the arc is by no means a constant; that if you treat the arc as possessing a resistance simply, then you must say the apparent resistance of the arc for a given length varies inversely as the current. When you double your current, the resistance of your arc becomes halved. If, however, you treat the problem in the other way (which seems more rational), as involving the consideration of a back E.M.F., seeing that the back E.M.F. is a nearly constant quantity, you

* Cantor lectures delivered before the Society of Arts.

Digitized by Google

must calculate the work done in another way—namely, as work done in driving a current against the opposing E.M.F. There would, in fact, be no work done at the crater surface if there was not located there something in the nature of back E.M.F. To put the thing in simple mathematical form : If V represents the number of volts against which you are driving the current—*i.e.*, the true back E.M.F. of the arc—and C stands for the number of amperes of current, then the work done per second is the product of those two. If we were dealing with a constant resistance, V itself would be proportional to the current ; hence the product of the current into V brings the current twice over into the expression for the work done. Where, however, we are not dealing with a constant resistance, there being a fixed voltage to do work against, we must use the law in this shape just given ; the work done in driving a current against a back E.M.F. is the product of the two. If the voltage against which you are working is a constant, it follows that the power expended is proportional simply to the current, not to its square, a conclusion which is justified by the fact that the amount of light given out is proportional also to the current, other things being equal.

Influence of Crater in Efficiency of Lighting.

Mr. Trotter's admirable paper deals, amongst many other things, with one very interesting practical point. Some years ago it was proposed by Sir James Douglass—a name so well known in connection with lighthouse work—to employ, for lighthouse illumination and projector lamps, a form of carbon rod different from that which had been previously used. If I am rightly informed, the old carbons originally used in the lighthouses in Dungeness and elsewhere were made from battery carbon or retort carbon, sawn into square sticks about a ¼in. each way. They were afterwards replaced by round rods of somewhat larger diameter, and for very powerful lights by still larger rods. Sir James Douglass seems to have thought he would obtain a better light, a more central, steady, luminous patch to project through his lenses, if he could avoid the wandering of the arc over the large surface of the crater. The wandering of the arc, when the carbons are too thick in proportion to the current used, is one of the things familiar to all who work with arc lamps. If you employ a larger size of carbon rod than is necessary for the size of the crater—that is, proportionally to the current—the crater will not be fully filled with light, but a luminous spot of the light will wander round and round unsteadily in the crater. Then at irregular intervals the crater wall will give way, sometimes on one side, and sometimes on the other, and you have loud hissing and extreme unsteadiness. It occurred to Sir James Douglass that if he fluted his carbons he would obviate the formation of a crater rim ; he would, instead, obtain a crater with an edge consisting of points at regular intervals with spaces between, and presumably a more steady arc. Mr. Meyer has sent me these two specimens of Sir James Douglass's lighthouse carbons. They look to me as if they were taken from an alternating-current lamp. Neither of them has a well-formed crater. There is here a second pair of fluted carbons, intended for a smaller lamp, which have the same peculiarity. Mr. Trotter examined the arcs made by using fluted carbons, and, reading between the lines, I judge that he was not favourably impressed with the arc produced under those conditions. The fact is, if you want a good light you must have a good crater. This I take to be the explanation of the attempt to improve carbons by coring them—that is, by making them tubular, and filling the bore with carbon of a softer quality. This device appears to have a beneficial effect in anchoring the arc, and preventing it from wandering round the crater, by giving it a kind of foothold. The soft core tends, in fact, to promote the formation of a crater, and consequently to steady the arc. With very short arcs, and arcs that hiss, the crater is generally very irregularly formed and much deeper as a cup than is the case in the long arcs. The mushroom growth that is observed with hissing or short arcs is formed at the expense, in fact, of material torn up from the bottom of the crater. This is but one of a number of irregular phenomena which really need not engage us further, but must, however, be taken into account in any complete account of the optics of the arc. The rapid changes of colour in the flame whenever the arc is in an unstable state are very curious.

Whiteness of the Arc Light.

Another very important point in the optics of the arc is its constant degree of whiteness. It was found by Captain Abney long ago, in 1878 or 1879, I think, that the relative amounts of the radiation of different colours—red, blue, yellow, and so forth—in the arc light are always the same, other things being equal ; the arc is, in fact, of a constant degree of whiteness, so much so that for years he has used it as a standard of comparison in his researches on colour photometry. This constant degree of whiteness, so far as it is true, is evidence of constant temperature, or possibly of constant temperature coupled with constant emissivity. It is a curious point that when the arc wanders from spot to spot, in the rapid fluctuations that sometimes occur—about which I shall have something to say presently—the apparent whiteness of the arc remains the same, although the intensity of it may vary—that is to say, one patch may look whiter than another patch by having more light coming from it, yet you do not get a change of colour. You cannot say that it is any redder, any greener, or any bluer—there is simply more light coming from it ; so that it appears that there may be something comparable to constant temperature, and yet different emissivities at portions of the same surface.

So three years ago Mr. Swinburne and I, independently, suggested that, seeing the arc is always (or was supposed to be always) of a constant degree of whiteness, the very best standard of white light would be that of a fixed area or patch selected from the crater of the arc (by means of a diaphragm having a very small hole in it). We could desire no more perfect standard of white light than one always equally white and of a fixed size. This suggestion of using a square millimetre, let us say, of incandescent carbon at arc temperature, as the standard of white light, was a very fascinating one. I did my best to have it taken up in Germany by the late Prof. Von Helmholtz. The last letter I ever had from him was on this subject. The suggestion has been put to trial both by Mr. Trotter in London and by M. Blondel in Paris. The result of it all is that, fascinating as the idea may be, it will not do ; not only are there inherent difficulties at the very high temperature that prevails in getting the light through the small diaphragm placed close up to the arc, but, as Mr. Trotter has found, the variations of the light are so extraordinary that at present it seems unlikely that we shall ever in this way attain a true standard of invariable amount.

What, then, are these variations about which I am speaking ? In the first place, if the carbon contains impurities the light is of lower intrinsic brightness. The soft variety of carbon used as a core in the cored carbons shows as a duller patch at that part of the crater. As an experiment I had an arc light carbon cut down lengthways ; there was fixed up against it a pencil made from the best graphite one could get—a pure natural graphite. This combination was, in fact, a carbon rod, half of which was ordinary arc light carbon and half of which was plumbago. Using this compound rod as a top carbon I found the crater to be unequally illuminated over the two halves. The supposed pure graphite shone less brightly ; it was white ; but it shone with a different amount of light from the patch of ordinary arc light carbon, just as the cores of the cored carbon pencils shone with a different degree of brightness. In using cored carbons you, in fact, sacrifice a little of the candle-power in order to obtain steadiness. It is a not unimportant fact that impurities lower either the temperature or the emissivity of the surface, and the result is a want of standard condition. The more recent discovery of Mr. Trotter—presently to be described—is much more upsetting.

Luminous and Non-Luminous Energy.

The energy that is given out by surface light is, unfortunately, not given out only as light. There is other energy of a non-luminous kind. I am not exaggerating when I say that only about one-twentieth or one twenty-fifth of the energy supplied to the arc, and emitted at the crater, is effective in producing illumination. To put it in a popular way, for every ray of visible light you have given out you have 24 or 25 rays of invisible light—that is to say, of heat—so that the luminiferous efficiency of the arc is something like 4 or 5 per cent. only. Of the energy spent, there is only some 4 or 5 per cent. which is effective in producing illumination. Here is a diagram intended to illustrate that. Using a proper kind of prism to disperse the rays, one may produce a spectrum. Such a spectrum has been given by various authorities : Müller, Tyndall, Abney, and Langley. From the recent researches of the three last named I have prepared the diagram (Fig. 19), in which different rays of luminous and non-luminous light are supposed to be plotted out before you. In this case the luminous spectrum occupies a very small part of the diagram. The smallest of the three curves is Captain Abney's curve of relative luminosity or sensitiveness of the normal eye to different kinds of light. The eye is most sensitive to light in the yellow or greenish yellow, and least sensitive to the red, and to blue and violet. What proportion do these radiations to which the eye is sensitive, and which are effective, therefore, for the purpose of illumination, bear to the whole amount of radiation ? Only this very small area underneath that curve of luminous energy as compared with the area underneath the tall black curve, which represents the spectrum of the total emission of visible and invisible rays from the arc. Right away down in the *infra* red you have this enormous development of waves of slow period—heat waves in fact. They are given out in far greater abundance than the waves which affect the eye as luminous waves. The ragged curve which is intermediate between the others represents to the same scale as the arc spectrum, a spectrum for an equal amount of light if derived from the sun. It shows how waves of a certain length are absorbed off by the intermediate atmosphere between us and the sun. This curve is taken from Langley. One of the things we have to look forward

Digitized by Google

to in the development of artificial light is the production of lamps which shall be of a higher efficiency than the arc lamp. They must, for an equal amount of energy supplied to them, emit a far greater percentage of waves of a length that will affect the eye as luminous waves, and a far less percentage of those longer waves which do not help the illumination, but which only warm us. Such a transformation has been wrought for gas lighting in recent years in the introduction of Dr. Auer's incandescent mantle. He discovered a material whose emissivity, at the temperature of the gas flame, is higher than that of the carbonaceous matters in the ordinary flame of coal-gas. It emits a greater percentage of waves of the sorts that affect the eye, and a lesser percentage of the non-luminous waves. The vacuum tube lamps, and their modern varieties, such as Tesla's

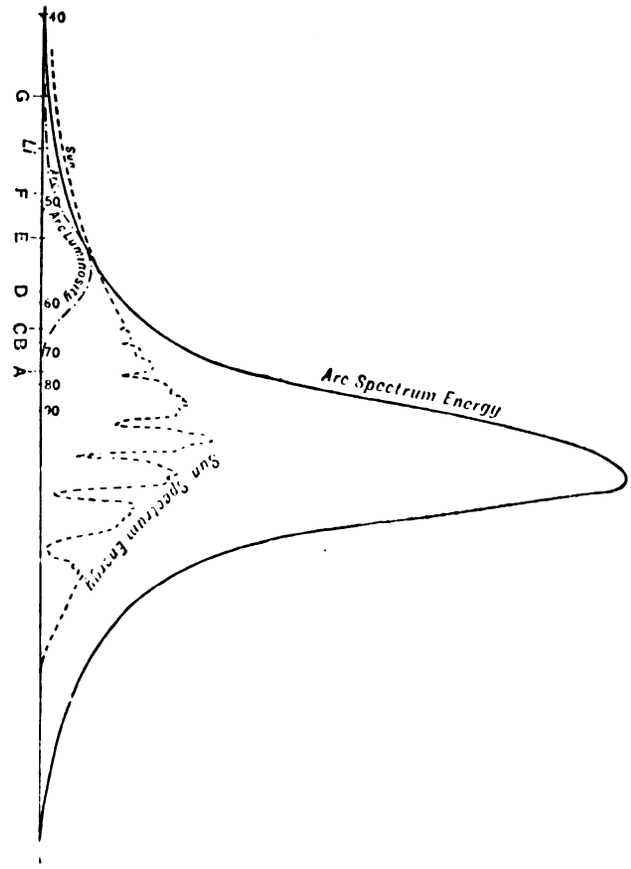

FIG. 19

lamps and Ebert's luminescence lamps, are attempts to procure a better specific luminescence from a given amount of energy.

ALTERNATE-CURRENT LIGHTING.

I have on the table here the means of producing an alternating-current arc. The alternating current may be turned on, and then the arc struck by hand between the two carbons. By means of a choking coil I am able to regulate the amount of light given out by the current passing through the arc, and with this lens I will project the arc on the screen, so that you may see the difference between the normal arc, as made with a continuous current, and the alternating-current arc. You will find that, in the latter case, the tips of the two carbons are heated almost equally to whiteness, and assume almost identical shapes. If the carbons are of the same quality, the heating and the consumption of them would be precisely alike, except for the slight difference due to the circumstance that the ascending hot gases around the arc make the upper carbon hotter. The two luminous areas on the two tips are of equal area and equal whiteness, and, as projected on the screen, appear as two luminous patches of equal size; but in neither the upper nor the lower carbon is there either a well-developed crater or a well-developed peak. The fact is, that each tip has to serve alternately as crater and as peak, so that the resulting form is a compromise. We are able then at once to recognise whether the arc is being supplied by a current that is continuous, or by one that is alternating. The distribution of light in the space surrounding the arc corresponds to this difference in the distribution of the luminous surfaces. Whereas the continuous-current arc throws its light (when the crater is at the top) mainly downwards, with a maximum at 40deg. to 50deg. below the horizontal, the alternate-current arc throws its light almost equally upwards and downwards, there being two maxima, one above and the other below the horizontal. But with the alternate current it is possible to cause the light to be artificially projected downwards on the whole, either by placing a mirror around the upper carbon (as in Fig. 12) to reflect down the light that is emitted upwards, or less advantageously, by employing a thicker top carbon, and a thinner bottom carbon. There is another important difference between the light of the alternate-current arc and that of the continuous-current arc which affords a ready means of discriminating between them. The alternate-current arc is subject to a regular periodic fluctation. The rapidly-reversing current pulsates, and the arc pulsates too. The current actually stops and then starts again in a reversed direction some hundred or more times in a second. The flame does not actually go out, but it dies down, and before it has had time to go out the current has started again in the opposite direction. If the flame did not thus persist, it would be impossible to operate arc lamps at all by means of alternate currents. I can show you by a simple experiment this fact of persistence. I take here a continuous-current arc, and clamp the carbons immovably at the normal distance apart while the arc is burning steadily. Now, by means of a reversing switch, worked by hand, I suddenly reverse the current. The light blinks at the instant of reversal, but does not go out. An interruption of, say, one-hundredth of a second does not put out the light: the flame had not time to die away. It is not accurately known what the maximum duration of an interruption may be, but it is known that arc lamps cannot be practically operated with alternating currents if the frequency is less than about 40 periods per second—that is to say, if there are fewer than about 80 reversals per second. That the light of an alternate-current arc does thus fluctuate can be made evident in the simplest possible way. If one whirls a white rod, or waves it rapidly up and down, in the light of the arc, one perceives a succession of images. When a rod is made to throw its shadow on the screen, and is then rapidly waved to and fro, the shadow is observed to be broken up into a series of maxima. A silver coin tossed into the air shows a succession of images as it falls. By merely shaking my hand in the light of the alternating arc, I appear to possess an enormous number of fingers. The current here used is derived from the generating station at Deptford, where Mr. Ferranti's machines work with a frequency of 85 periods per second. Consequently we have 170 successive images per second for any quick-moving body. I have frequently found out whether arc lamps were worked with alternating currents or by continuous currents by standing under a lamp-post at night, and twirling my walking-stick. You can tell an arc lamp that is alternating by another circumstance—viz., that in addition to any fizzing or hissing that there may be, you hear a kind of continuous hum. In the lamp now before you you may hear the hum of the machines at Deptford. If I increase the current, you will hear it still more loudly. The loudness of the hum also depends on the form of the individual waves of current.

EFFICIENCY OF ALTERNATE-CURRENT ARCS.

There has been some discussion of late on the question whether the alternating-current arc was as efficient as the continuous-current arc—that is to say, whether for a given consumption of energy you obtain an equal proportion of light. Prof. Fleming has made measurements, and written learnedly on the subject. I do not dispute the accuracy of his observations, or that of others who had made observations on the subject. I wish to give you an absolutely *à priori* view. This is a matter I have not measured myself, therefore I am absolutely unprejudiced, but it seems to me perfectly absurd to suppose that, if you take the right mechanism, select the right size and quality of carbon, and use it properly by the light of experience, applying the appropriate amount of current, there will be any difference whatever in the efficiency of the alternating-current arc and that of the continuous-current arc. I do not see where there is room for any difference. At one time it was supposed that incandescent lamps were not as efficient if worked with alternating currents as with continuous currents. That heresy was long ago exploded by Profs. Ayrton and Perry when they showed that it was merely a question of getting the right voltage appropriate to the measurement lamp. I am bound to say I think the same kind of considerations apply here also. Since the heating effect of a current is proportional to the square of the current strength, what difference does it make, what difference can it make, whether the current is going in one direction or in another? If you spend the right amount of energy on the right amount of carbon by raising it to the right amount of temperature, you are bound, other things being equal, to have equal results. If you arrange your things badly so that some of the energy is not spent, as it ought to be, on heating the carbon white hot, I grant you may get a different result; but it seems to me, from *à priori* reasoning, to be absurd that you should not have equal efficiency with the alternating current as with the continuous current.

SPECTRUM OF THE ARC.

My next experiment is to project upon the screen the spectrum of the arc. Arrangements are made in the following way: First of all, the arc is produced inside a lantern; it is then focussed by a lens upon a small auxiliary screen 3ft. away from the arc. This screen has a narrow slit down it, the image of

Digitized by Google

the arc being formed on a slit. Through the slit, then, there passes out a vertical slice out of the arc. In this slice we shall have a bit of the top carbon, a bit of the arc in between, and a little bit of the bottom carbon, one above the other. The light of this luminous slice is then passed through a prism, and on through a focussing lens, producing on the screen a spectrum of that portion of the arc complete, from the red end on the right to the violet end on the left. Now notice what that spectrum consists of. The upper luminous streak is the white light from the crater spread out into its various component colours in their proper order one after the other. The light of the bottom strip, which also goes from red to violet, is the light from the peak of the negative carbon. The apparently dark patch in between them shows you the spectrum of the pale flame or arc. Only those who are near can see it properly, but in this comparatively dark tract between the upper and lower carbons the spectrum shows a number of nebulous bands, two in the green, a brighter one in the bluish green and another one about the end of the blue or beginning of the violet. Those bands are the well-known spectra of the element carbon, so that we have here the optical proof that the flame between the two carbons consists of carbon vapour in an incandescent state.

THE ENCLOSED ARC.

More properly belonging to the subjects comprised in my first lecture is the matter next to be mentioned of the peculiar effect produced on an arc by burning it in an enclosure which prevents access of fresh air. The properties of the enclosed arc have been investigated by Mr. Marks, to whom is due the disposition which I here exhibit. It may be fitted to any ordinary form of arc lamp. The lower carbon projects through and supports a metal disc with a raised rim, on which stands a small glass jar about 3in. in diameter. The upper carbon comes down into this through a rude stuffing-box at the top of the jar. The arc is formed in the usual way, only it happens to be enclosed, so that the air cannot come in from below or readily pass through the rough stuffing-box at the top. The air in the jar is in a few minutes deprived, by combustion, of its free oxygen; so that from that time onwards the arc is burning in an atmosphere that will not support combustion. As a consequence the actual waste of carbon is much smaller than is usually the case. In some experiments on the ordinary arc, made by Mr. Preece, with a Brockie-Pell lamp, using about 6½ amperes at 50 volts, with a 13mm. carbon for positive and an 11mm. carbon as negative, the mean consumption per hour per ampere was found to be, for the positive carbon, 3·52mm. (length), or 0·504 gramme, and for the negative carbon, 2·86mm., or 0·176 gramme. (Dr. Strecker gives, as the experience in Germany, 0·75 and 0·375 gramme respectively). Now, this consumption of carbon may, as Mr. Marks has shown, be greatly reduced by simply preventing access of fresh air.

This actual lamp has been tried. My friend Prof. Walmsley, of Edinburgh, has been good enough to communicate to me the figures obtained during a run of 14 consecutive hours. The carbons were those ordinarily used in Brockie-Pell lamps, but the actual lamp used was of Brush-Sellon pattern. The current was 10 amperes, and the mechanism was adjusted to give a rather long arc. Of the positive rod the length consumed per pair when burning open was 47mm.; when enclosed, only 2·84mm. Of the negative carbon, the length consumed per hour when open was 18·7mm.; when enclosed, only 0·62mm. The positive carbon when burnt in this way only burns at about one-tenth of the rate at which it burns away in air, while the negative carbon only burnt away at about one-thirtieth of the rate at which it burns away in free air. The total consumption when enclosed, is, therefore, about one-twentieth part of what it would be for the same current when the arc was burning in open air. There is, however, one drawback to the use of an enclosing vessel like this—viz., that the interior of the vessel gradually becomes coated with a brown dust which obscures the light On that Prof. Walmsley made some observations, and came to the conclusion that after 18 hours the light was approximately about half of what it would have been without the globe. As a matter of fact, it is a brown deposit, which cuts off rather more of the green waves than it does of the red waves.

(To be continued.)

Invention.—Mr. E. P. Thompson continues in the December number of *Electric Power* his endeavour to reduce to principles the process of making new inventions. He classifies inventions under various heads, such as "Imitation," "Change of Material," and so on. When "Faure plastered the lead plates of an electric battery with red lead, and saved several weeks and months in the formation of lead compounds by the electrolytic process," it was a "striking example of imitation." Perhaps; but it does not help much in teaching how to invent.

REPORT ON THE LEEDS TRAMWAYS BY DR. J. HOPKINSON, F.R.S.

Below we give the report recently presented by Dr. Hopkinson to the Leed Highways Committee It may be remembered that this committee in October last passed a resolution, "That the necessary steps be taken for the extension of the Roundhay tramway to the Canal Gardens at the Park; that the overhead electric traction system be continued from the junction of the Roundhay tramway at Sheepscar along North-street and Briggate; that in Boar lane, from Briggate to the Yorkshire Banking Company's premises, an installation of the conduit system be laid; that the overhead system be then continued along Wellington-street and Kirkstall-road to Kirkstall Abbey, and that central poles be used wherever practicable."

Dr. J. Hopkinson was then asked to consider the matters and reported as follows:

I have paid two visits to the city for the purpose, and have inspected the tramway from Kirkstall to Roundhay, the existing electric station at Burmantofts and the proposed sites for the generating stations at Armley road and Crown Point road. The distance from Kirstall to Roundhay Park is seven miles, and hence the length of a complete round trip will be fourteen miles Having regard to the fact that a considerable portion of the distance run is through the city, it is clearly impossible to maintain a high speed. I do not think that a greater average speed including stoppages, than seven miles an hour can be calculated upon. I therefore assume that the cars will be run at an average speed of seven miles an hour, including stoppages. If this be so the average time for a car to complete the circuit from Kirkstall to Roundhay Park and back again will be two hours. As the cars run at intervals of 7½ minutes, this will require 16 cars constantly running, or, allowing four cars as spares, a total of 20 cars. This number, will, of course, be the same whatever system of conductors were used.

Where the Poles Should be Placed.—The questions with regard to the conductors which remain open are, whether, with the overhead conductors, poles in the centre of the roadway should be used, or poles at the side, with wires crossing the street, from which would be suspended the conducting wires which supply the cars. A good example of centre poles can be seen in the arc lighting poles of the St. Pancras Vestry. These are placed in the middle of the roadway, and are protected by a small island of pavement from danger from passing vehicles. This, in my judgment, forms a very neat arrangement. The presence of the poles does not in any way obstruct the traffic, but rather facilitates it by dividing it on the two sides of the road. The islands, too, are convenient for people crossing the roadway, giving them a place of safety if the traffic is at all crowded. The present distance between rails is 3ft. 3½in., the width of the cars 6ft. 8in. to 7ft. Deducting 4ft. 8½in., the gauge of the rails, the cars project 1ft. to 1ft. 2in. on either side into the space of 3ft. 3½in. between rails. This will of course be increased, say, to 4ft. 6in., which will leave from 2ft. 2in. to 2ft. 6in between passing cars. I am informed that a minimum width of 34ft. between the kerbs will be secured from the end of the present electric tram to Kirkstall. This would be divided as follows:

Side space.	Track.	Space between rails.	Track.	Side space.
10ft. 0½in. ..	4ft. 8½in. ...	4ft. 6in. ...	4ft. 8½in. ..	10ft. 0½in.

The car would project 1ft. to 1ft. 2in. into the side space, leaving 8ft. 10½in. to 9ft. 0½in. clear for other vehicles. The appearance of a line of centre poles would be much better, in my judgment, than any other arrangement, and they could further be used for arc lights, if desired. I should, therefore, prefer centre poles, but this would not in any way interfere with the use of wires stretched across the streets in places where poles might from any cause be inconvenient. This would be particularly the case where there are points or where rails cross each other. It has been suggested that the supports carrying the overhead conductors, be they poles or cross wires, could be placed at a greater interval than has hitherto been usual. This is just one of those practical points for which one must rely upon experience, and I should not recommend any deviation from the results of such experience—that is to say, the poles should be placed at intervals of 40 or 50 yards.

The Conduit Systems.—When I was recently in the United States I gave special attention to what had been done in underground electrical conduits for tramway purposes. There are two such conduit systems in Washington, and another has been laid down in New York. Some years ago I also gave special attention to the conduit system in Budapest, and visited that town for the purpose of making a careful inspection. The conduits there laid down have, on the whole, worked extremely well. The principal objection to the conduits, as laid down in America, is their great cost. I was informed that those in Washington cost about £20,000 per mile of single track. Other serious objections are that they necessitate a slot in the roadway of about ¾in. wide; and in the particular case of Leeds, where it is proposed to combine an underground conductor in one part of the tramway with an overhead conductor in another part, there is the further objection that it would be necessary to stop the car for a very appreciable time for the purpose of detaching or attaching the plough, as it is called, which makes the connection with the underground conductors. These objections, of course, are by no means insuperable if no better method could be found. There is, however, a method of supplying current to tramcars which is free in a greater or less degree

Digitized by Google

from all three of these objections. This method, to my knowledge, exists in three different forms in the hands of three different American firms. For the present purpose I need refer to only one of them. According to this method, the slot is entirely absent, and its place is taken by a series of cast-iron pieces projecting very slightly indeed above the roadway at intervals of about 13ft. from each other. These pieces are only connected to the supply of electricity at times when they are covered by the car; at all other times they are inoperative and dead, so that no shocks can be received from them either by horses or pedestrians The cost of this system is considerably more than the cost of overhead conductors, but is considerably less than the cost of a well-laid conduit. The slot, as already stated, is absent, and it would be possible to so arrange matters that the transference from one source of supply of current to the other would be made without actually stopping the cars. If it were found that a stop were desirable, as a matter of convenience, this might be made exceedingly brief. A tramway has been working in Washington on this system for 18 months very satisfactorily. I inspected both this tramway and an experimental tramway in the Westinghouse works at Pittsburg. I should, therefore, recommend that for the tramway through Boar-lane the enclosed conduit system, such as that to which I have referred, should be adopted. All other conductors than those for the delivery of current to the cars should be laid underground.

Electrical Pressure.—The next question is that of the electrical pressure at which current is to be supplied. Five hundred volts has been sanctioned, and is used in Bristol, and I have ascertained that it is the intention of the Board of Trade to sanction this pressure as the maximum pressure in other cases. There is no reason why any person should come in contact with the supply conductors at all, and I know by personal experience that the shock from 500 volts, though disagreeable, can be received with absolute impunity. The economy obtained by using the highest admissible pressure is, of course, considerable when transmission has to be made over a substantial distance, and I should therefore recommend that 500 volts be the working pressure for the Leeds tramways.

The current will return from the cars to the generating station by the rails and such additional conductors as may be necessary. This requires care in carrying it out. Without such care it is obnoxious to the objection that a considerable part of the currents may return from the cars to the station through the earth instead of through the rails, and in so doing they may cause, first of all, electrolytic action upon gas-pipes, which may in time be sufficient to eat holes into the pipes and cause serious danger from leakage: secondly, these earth currents may disturb the telegraphs; and, thirdly, they may disturb the telephones. With regard to the telephones, the cause is not solely currents returning through the earth, but is in part inductive. The Legislature, however, has put the duty of protecting themselves upon the Telephone Company, and so far as it is concerned it is only necessary to take such precautions as are convenient and inexpensive. With regard to the gas-pipes and to the telegraphs, the Board of Trade have laid down certain stringent regulations which in their opinion should prevent mischief, and which can be effectively carried out by proper care. In my judgment however, it would be well to so construct the system that the Board of Trade conditions should be more than fulfilled. This can be done by giving sufficient attention to the laying of the rails and to their conductivity, and to the general design of the system.

The Generating Plant.—Of the general questions that have to be considered, the next is that of the location of the generating plant. You have in Leeds a number of refuse destructors, in which a considerable amount of heat is generated. Is it worth while to utilise this heat? The primary question is, How much can we save thereby? I shall show presently that for working the seven miles of tramway to be first put down, the indicated horse-power will be about 200, or rather less. This will require a daily consumption of about four tons of coal. Coal in Leeds is cheap—I understand about 6s. per ton—and hence the total annual saving, if the coal bill could be totally abolished, would only amount to some £450 a year. When the whole town is supplied with electrical tramways, the power required will be increased fourfold, or slightly more. The saving then effected would be some £1,800 a year. To effect this saving, however, certain serious inconveniences will be caused. In the first place, in order to supply the power required for the whole town, more than one destructor station would have to be utilised, and hence there would be at least two generating stations instead of one, which would be all that would be required if the heat were generated from coal. Special boilers would have to be provided for the purpose of generating heat from the products of combustion of the destructors, but this would not relieve the city from the necessity of putting down additional boilers to generate steam from coal, because the destructors do not now work, and I understand there would be difficulty in causing them to work on Sundays. It may be suggested that electric accumulators might be used for effecting the supply of current on Sundays, these being charged during the week from the destructor stations. It would, of course, be possible to accomplish this, but at very great cost; for the accumulators would have to store the considerable amount of energy required for nine or ten hours' running These would, therefore, have to be of a very large size, and correspondingly expensive. In fact, if the destructors were used, I should say, provide for Sundays by a special system of boilers, and not by accumulators. From what I have stated, however, it can very readily be gathered that a single generating station, working in the usual way with steam-boilers heated by coal, will be the most economical and convenient. This, of course, sets us free in the choice of the station—in itself a very considerable advantage, and if there is no strong reason on the ground of cost for land, or the like I should prefer the station marked No. 3 upon the plan, on the north side of the River Aire, at the end of Crown Point road. This site has the advantage of being the most central—a very important matter from the point of view of economy—and also the advantages that condensation water can be obtained for nothing, and that coal can be delivered by water cheaply.

The Power Required by the Cars.—What power is required for propelling the electric cars? Experience in this country and in the United States shows that, running at such a speed as you propose to run, a car can be propelled a mile with the expenditure of one Board of Trade electrical unit. In order to bring this in a shape more familiar to engineers, I should state that a Board of Trade unit is 1⅓ h.p. exerted for an hour. To put it another way, it is 2,640,000 foot-pounds. Hence, to run the whole 16 cars required on the tramway to be first laid down for one hour at seven miles an hour will require 112 Board of Trade units But whilst a Board of Trade unit is the amount of work required to run a car for a mile, this is very variable from time to time. When the cars are just starting, they require a very much greater current, and, of course, they require more when ascending a steep gradient. It may be taken, however, that the maximum power required by a car is more than three times the average power, or to put it another way, that whereas the average power required to propel a car is 9 h.p. to 10 h.p., the maximum power required in starting it on a gradient is 33 h.p. The effect of this great variation in the power on different parts of the tramway line is very important. Take any district, for example, in which the number of cars is few, say only three; it is quite possible—nay, certain, that occasionally all these three cars may be starting at one and the same time, demanding in that district the supply of 100 h.p. Suppose, on the other hand, that the number of cars in a limited distance is large, say 15 or 20, it is extremely improbable, one may almost say infinitely improbable, that all these cars will be starting at the same time, and hence, when the number of cars is great, the average power will differ less from the maximum power. But consider the application of this to a town such as Leeds, when the whole tramway system shall be developed in the centre of the town. The power required to propel the cars in the neighbourhood of Boar-lane will not differ greatly from constancy, but the power required on parts of the line remote from the centre of the town will vary very greatly; for example, the power in the neighbourhood of Roundhay Park, say, the last mile and a half of the road, will vary from nothing at all to 100 h.p, and the variations from nothing to 100 will occur with very great rapidity. But the duration, both of times of great demand and no demand, will be very short indeed. If the supply to the distant parts of the tramway system be effected solely by the agency of the central generating station, conductors will have to be provided of adequate size to carry, without undue loss of pressure, the whole 100 h.p.

The Value of Accumulators.—This can, however, be avoided by the proper application of accumulators. This application is precisely analogous to the familiar use of hydraulic accumulators for the hydraulic supply of power when the demand is variable. An accumulator would be placed in the neighbourhood of Roundhay, in any place which might be found convenient. This accumulator would be supplied with current from the generating station, the current being practically constant. Whenever the heavy drain of 100 h.p. in its neighbourhood was required, two-thirds of this power would be supplied by the accumulator, exactly in the same way as when many presses are required to work at once, the water is supplied to them from the hydraulic accumulators. The space required for such an accumulator would not be large; a room 20ft square would be sufficient if more were not available. A second accumulator would be placed towards the Kirkstall end of the line. It would be in all respects a duplicate of the accumulator at Roundhay. The accumulators would be worked under favourable conditions, as they would at all times be almost fully charged. Working under the less favourable conditions of electric lighting, accumulators can be maintained by contract with the manufacturers for less than 10 per cent. of their actual cost, and even at this rate it is more economical to maintain one's own accumulators if the management is reasonably careful. These batteries of accumulators would not require the constant attendance of a man; they would really work automatically, just as hydraulic accumulators do. They should, however, be frequently inspected. Accumulators have been used with very great advantage in the remarkably successful tramway from Douglas to Laxey in the Isle of Man, and under conditions analogous to those of Leeds. If the only question were that of the tramway from Kirkstall to Roundhay Park, I should recommend a third accumulator in the neighbourhood of the power station, because even there the variation in load would be very considerable. But one must look at the probable future development. When there are several tramlines all converging upon Boar-lane, the average effect of the larger number of cars will be felt, and the load will consequently vary very much less. There is another incidental advantage of the use of accumulators on the more distant portions of the line. It makes it much easier to conform to the Board of Trade regulations, which require that the difference of electrical pressure between the remotest parts of the line and the generating station shall not exceed 7½ volts. If accumulators are used it is only necessary to provide such return conductors, be they rails or be they specially

Digitized by Google

provided, as will be sufficient to carry the average return current with less difference than 7½ volts. If, on the other hand, accumulators be not used it is necessary to provide conductors for the return of adequate size to carry the maximum current, which, as already stated, is three times as large as the average current. Another advantage in the moderate use of accumulators is that they provide the means of moving a few cars along the line or in the depôts even when the engines are standing. This would shorten to a certain extent the hours during which it would be necessary to run the generating machinery. I would have it understood, however, that though I am perfectly clear that accumulators will be a great advantage in working this tramway, I do not consider them by any means an absolute necessity. The line could be worked without them undoubtedly, but with less economy.

The Plant.—The next question to be considered is the size of unit to be used for generating the current. If there were no intention of extending the tramway I should recommend such a unit of power that two units would be capable of doing the work and would then put down an additional unit as spare, making three in all. But I must assume that we must provide for power at least four times as great as will be at first needed. Working as I have suggested, with accumulators, on the more distant parts of the line, 200 i.h.p. would be needed to propel the cars. If accumulators were not used, about 300 i.h.p. would be needed in order to ensure that the engine power should be adequate to meet the maximum probable demand. I should therefore propose, in the first instance, to put down two complete units of power, each capable of giving 200 h p.—that is to say, there would be two boilers, each of 200 h.p. or thereabouts, two engines, and two dynamos, each driven by its own engine. In the first instance, this would no doubt be a little more costly than putting down three units of power each of 100 h.p. But when the power is multiplied fourfold the advantages in favour of the larger unit will be great. We may then look forward to putting down six boilers, six engines, and six dynamos, each set capable of giving 200 h.p. Four of these would be in use at one time, and two would be spare—one ready for use, and the other, if necessary, undergoing examination or repair. The switchboards and instruments would be arranged, in the first instance, in such wise that they would be adaptable by additions and without alteration to the larger work. The buildings also should be constructed of adequate size in the first instance, or be so arranged that they would be readily enlarged. The cars should, I think, be electrically lighted by the same source of current as that supplied for propelling them. The lighting could not be expected to be absolutely free from variation of brilliancy, as to secure this would mean a considerable increase of cost. But it would be far better than any other artificial light available.

The Rails.—The question has been put to me by the city engineer as to whether, from a purely electrical point of view, the 70lb. rails would be of adequate section—that is to say, viewing them entirely as conductors, and apart from any question as to their being strong enough to mechanically carry the traffic. Seventy-pound rails would certainly be sufficient for the average current—that is to say, they would be sufficient if batteries were used. I think it would be worth while, however, for the committee to consider the possibility of an increased traffic, and an increase of the size of the cars, at some future time. In the event of either the traffic increasing or it being decided to omit the use of accumulators, 70lb. rails could still be used so far as the electrical conditions are concerned. It would be necessary to put in additional copper return conductors at an earlier time than would be necessary if the heavier rails were adopted.

The Capital Outlay—The schedule at the end of this report gives my estimate of the capital outlay for plant for the line from Roundhay Park to Kirkstall. It will be observed that this estimate does not include anything for buildings, as this will greatly depend upon the style in which they are done. It does not include the getting out and making good of the ground for laying the underground conductors, for poles, or for the bonding of rails It does not include the rails themselves, and it includes nothing for engineering expenses and contingencies. For this last item I should add 10 per cent. in order to be upon the safe side, although it is my experience that no addition to my estimates has been required for contingencies. It will also be observed that I assume it is necessary to treat the whole line as though there were no tramway already in Leeds. I have inspected the machinery at Burmantofts and the conductors already at work. I am of opinion that the engines and dynamos at Burmantofts will not be suitable for permanent use—the engine is not condensing, and it is not compound ; the dynamos are arranged to work 300 volts, instead of 500 ; and, lastly, the machinery would have to be removed in order to make it useful. But I think it is extremely probable that the overhead conductors might be usefully employed, at all events in the first instance. It is a little surprising how small a part of the whole expense of an electrical tramway consists in the actual providing of power. The cost of coal, oil, water, and wages at the generating station, other than wages for repairs, should be less than ½d. per car mile run, whereas the cost of wages of car driver and conductor will be more than 2d. per car mile run.

Summary.—I recommend that there should be a single generating station for the whole of Leeds ; that this station should be at the end of Crown Point-road, and hence that no attempt should be made to utilise the heat of the destructors. The station I should recommend would be one which could be developed by mere additions in such wise as to supply the whole of the current required for the completed scheme set forth in Mr. Hewson's report, or for any reasonably probable additions thereto. The indicated horse-power required for a 7½ minutes' service between Roundhay Park and Kirkstall would be 200. I should recommend that this be provided as a single engine, with another engine as a standby. The number of cars required would be 20—16 running and 4 spare. Each car would have two motors and the motors would be capable of developing together 33 h.p , but the average power required from the two would only be 10 horse. This assumes that the series-parallel control were adopted. This method is almost universally employed in the United States, and is used in a portion of the cars on the present Roundhay tramway. I am of opinion that trolley wires carried from central poles would be most convenient from the end of the present tramway to Kirkstall, and that probably the present conductor would serve for the rest of the route. The proper voltage to employ is the maximum which the Board of Trade sanction—namely, 500. By the ground being surcharged with electricity I understand is meant the possible effects of return currents. From this cause it is absolutely impossible that any effects to persons could result. I am also of opinion that no danger would result from the overhead wires, because these wires cannot be touched, and even if they were touched no serious consequences are to be apprehended. Electrolytic destruction of gas or water pipes would be rendered small by adhering to the Board of Trade regulations ; indeed, quite negligible by adopting a standard, as I would propose, even higher than is proposed by the Board of Trade. The working of telephones will probably be interfered with by the tramway, but the Legislature has put the onus of preventing such interference upon the Telephone Company, and not upon the tramways. If the Board of Trade regulations are carried out, there should be no interference with the telegraphs. A thoroughly effective electrical tramway could be laid with 70lb. rails. But if 70lb. rails were adopted it would be necessary, when the whole system is completed, to make use of a certain amount of copper conductor as an aid to the steel.

Schedule.	£	s.	d.
Trolley wire erected with insulators, 14 miles at £190	2,660	0	0
Poles for two trolleys, seven miles at £1,196 per mile	8 372	0	0
Bonding rails, at £150 per mile of single track	2,100	0	0
Seven miles of 0·15 square inch cable, at £317 per mile	2,219	0	0
Closed conduit for 310 yards of double rail, at £1 12s 6d. per switch	251	17	6
Twenty cars, at £750	15,000	0	0
Two boilers, each 200 h.p., with steam-pipes and economisers, at £700	1,400	0	0
Two condensing engines, at £1,400	2,800	0	0
Two dynamos, at £600	1 200	0	0
Switchboards and instruments	740	0	0
Two batteries, at £500 each	1,000	0	0
Instruments and switches, at £70 each station	140	0	0
Total	£37,882	17	6

DOVER ELECTRICITY SUPPLY COMPANY.

REPORT BY PROFS A. B. W. KENNEDY AND S. P. THOMPSON ON THE TESTS OF THE PLANT IN THE STATION.

The tests described in the following report had for their main object the determination of the capacity and efficiency of the plant supplied by the Brush Electrical Engineering Company, Limited, to the Dover Electricity Supply Company, Limited, under a memorandum of agreement and specifications dated November 20, 1892. The chief conditions in the specification affecting the capacity and efficiency of the plant were the following :

1. The output of the alternators to be 50 kilowatts, 75 kilowatts, and 100 kilowatts respectively, at an E.M F. of from 2,000 to 2,200 volts.

2. The output of each of the two exciters to be 12·4 kilowatts, or, say, 190 amperes at 65 volts.

3. The output of each of the two feed pumping engines to be equivalent to the full power of all the boilers.

4. The combined efficiency of the steam alternators to be 78 per cent. for the 50 and 75 kilowatt sets, and 80 per cent. for the 100 kilowatt set.

5 The steam consumption of the engines at full load not to exceed 19·5lb of water per indicated horse-power hour for the 50-kilowatt set, 19 0lb. for the 75 kilowatt set, and 18·5lb. for the 100-kilowatt set.

6. The energy absorbed in exciting the field magnets of the alternators not to exceed 2½ per cent. of the full output of the generators.

7. After a six hours' continuous run at full output, the temperature of no part of the armature or magnets is to exceed 60deg. F. above that of the atmosphere of the engine-house taken one minute after stopping the machine, on the side remote from the engine, and at no time to exceed 90deg. F. above the temperature of the atmosphere.

8. The insulation resistance between the whole of the conductors and the framework of the generator taken before and after a test at full load at any time not to be less than for the armatures 500,000 ohms, for the magnets 400,000 ohms, and the insulation of the armature to be capable of resisting a testing current at 4,500 volts alternating.

Digitized by Google

9. The fall in potential on a non-inductive circuit between half-load and the maximum output, with constant speed and constant excitation not to exceed 150 volts.

10. Each of the main engines and alternators and the exciter engines and exciters to be subjected to a six hours' continuous trial at full load, and subsequently the two exciters to be tested in parallel with each other, and in all like manner all the alternators to be tested in parallel with each other, for two consecutive hours on from three-quarters to full load.

11. The circulating and feed pumps and engines connected with them to be tested at full working capacity for six consecutive hours.

The tests took place in the station at Dover on October 7, 8, 9, 10, and 11 last, and were carried out by ourselves and a special staff of trained observers whom we sent down to Dover for the purpose. The leading results of the experiments are set forth in the annexed tables; and on the whole matters referred to we have to add the following remarks, taking up the various points in the order in which they have been enumerated above:

1. No. 4 set was tested first at various loads, and, finally, during a continuous run of six hours at full power (50 amperes at 2,000 volts). The next morning the remaining machines were tested not only at full load, but at an output 20 per cent. in excess of full load. No. 3 set was run at 55 amperes and 2,200 volts for five hours and then at normal full load for another hour. No. 2 set was run at 39·5 amperes and 2 000 volts for five hours and then at 41 amperes and 2,200 volts for an hour. No. 1 set was run at 25 amperes and 2,000 volts for five hours and then at 27·5 amperes and 2,100 volts for an hour. Thus No. 1 machine was overloaded by 16 per cent., and Nos. 2 and 3 machines by about 20 per cent. All machines ran satisfactorily at these overloads as well as at their nominal maximum output. In every case the load was obtained by the use of tubs, so as to be strictly non inductive. The current was measured on Kelvin ampere-gauges, and the volts on Ayrton and Mather electrostatic voltmeters, in addition to the switch pillar instruments, and we believe that the measurements so made are for all practical purposes completely accurate.

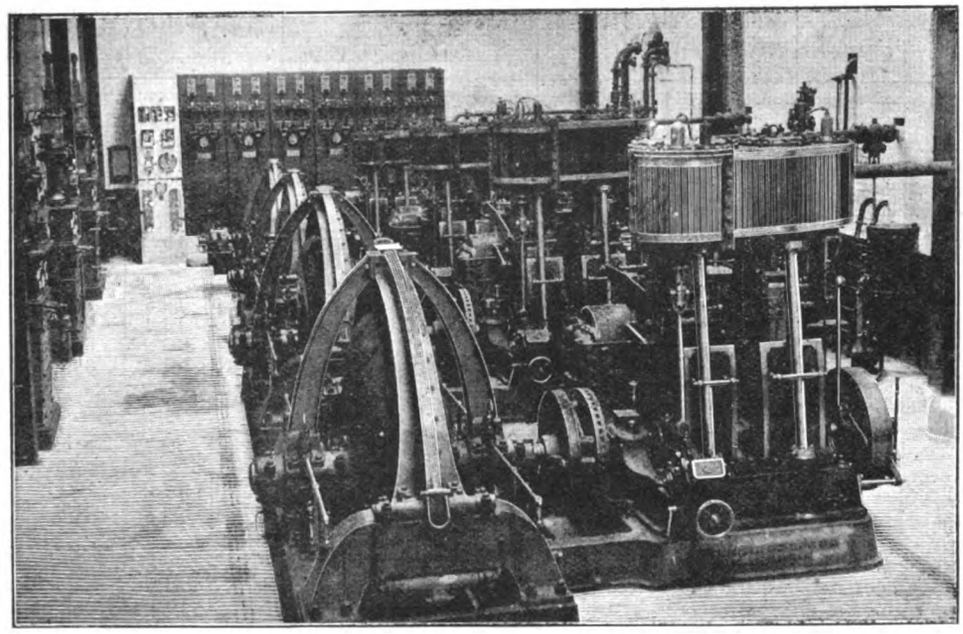
2. Each of the exciters was run on an external resistance at full load for about six hours, and gave its full output.

3. The feed pumping engines could not be tested to their full output, as we were unable to get more than enough work for one boiler. The maximum load which we were able to put upon any pump was between 7,500lb. and 8,000lb. of water delivered per hour. Each of the two pumps appeared able to furnish this delivery with ease.

4. The specified combined efficiency has been, on the whole, considerably exceeded. No. 1 gave 76·8 per cent. at full load and 80 per cent. at 17 per cent. overload. (In this case the machine was driving its own exciter, and the exciting watts are added to those of the alternator in computing the output and efficiency.) No. 2 gave 80·6 per cent. at full load and 81·0 per cent. at 20 per cent overload. Nos. 3 and 4 gave a mean of 81·1 per cent. at full load, and No. 3 gave 83·7 per cent. at 20 per cent. overload. Thus, although No. 1, the smallest set, has fallen very slightly short of the specified efficiency at nominal full load, it exceeded it when overloaded, and the other three sets have very considerably exceeded it, even at their nominal full loads, and we consider the results obtained in this matter highly satisfactory. In order to obtain the fullest information as to the efficiency of the machines, we indicated them not only at full load, but also at various smaller loads, as well as when running excited only. The detailed results of these tests are set forth in the tables. In all these experiments Crosby indicators were used, with tested springs, and the electrical instruments were read, the indicator diagrams taken and the revolutions noted simultaneously by separate observers. In the case of No. 1 machine, indicator diagrams were also taken at several different powers while running on the circuit in the evening. In this case the load was one which had considerable self induction, in consequence of the number of transformers on the circuit, and it was found that the apparent electrical horse-power (corresponding to the product of amperes and volts) exceeded the real electrical horse-power by about 13·5 per cent. over a range between 35 e.h p. and 60 e.h.p, the difference between the apparent and real output being, in fact, very nearly a constant percentage over this range. No doubt the difference will tend to diminish as the total load increases, as we believe that many more lamps can be served from each transformer than are at present connected up.

5. The steam consumption of the engines was measured by weighing the water passing away from their surface condensers. In the case of No. 1 set this amounted to 19·7lb. per indicated horse-power hour at full load, and 20·2lb. per indicated horse-power hour at 17 per cent. above full load. For No. 2 set the figures were 20 8lb. per indicated horse-power hour at full load, and 20·3lb. at 20 per cent. above full load. For No 3 set the figures were respectively 19·3lb. and 19 6lb, and for No. 4 set the consumption was 19lb. per indicated horse-power hour at full load. These figures are a little above those which have been guaranteed, but as the efficiencies of the machines are also above the guarantees, the consumption of steam per electrical horse-power hour, which is the really important matter, is practically the same as that corresponding to the specification. We therefore consider the results as to steam consumption to be quite satisfactory. We made consumption tests at various loads below full power, and the figures for these tests are given in the tables.

6. The measurements of magnetising energy were made by means of the station instruments in the switch pillar, which have been taken as correct for this purpose. A calibration made in the station after the tests showed that their errors were, at any rate, sufficiently small to be negligible. The percentage of magnetising energy to total output are shown in Tables II., III, IV., and V., from which it will be seen that they are (with the exception of No. II.) somewhat larger than the specified ratio of 2½ per cent.



View of Engine Room, Dover Electricity Works.

7. The temperatures of the alternators at the end of six hours' continuous full power run appeared to be in every case not only well within the specified limits, but quite exceptionally low. The two larger machines were practically cold after their six hours' full power run.

8. We regret that we were unable to make any measurement of the insulation resistance of the machine, as the testing set at the station was found to be out of order, but we have no reason to suppose that the insulation was not quite satisfactory.

9. Instead of measuring the fall of potential directly, we measured the excitation at constant speed and constant E M F., which gives the same proportionate result, and is more readily determined. The results are given in Table VI., and show that the variation differs greatly from 7½ per cent. (which corresponds to 150 volts in 2,000) in the different machines. In Nos. 1 and 4 it averages about 12 per cent., in Nos. 2 and 3 about 3·6 per cent. It is to be noted, however, that we could only measure the excitation at the terminals of the field resistances, and not at the terminals of the field windings themselves. This probably accounts for the obvious discrepancy of these figures. Within reasonable limits of variation, however, it does not appear to us that the constancy of excitation is a matter of any practical importance.

10. The full power runs of the main engines have already been mentioned. The engines, as well as the alternators, ran well, but it appeared to us that the consumption of lubricating material was somewhat unusually large. It may well be that this matter will rectify itself when the engines have run somewhat longer. No difficulty

was found in running the exciters in parallel. Alternators Nos. 1, 3, and 4 were run in parallel at different loads in accordance with the terms of the specification, and ran, in general, satisfactorily.

11. The circulating and feed pumping engines were run for much more than the specified period of six hours at as great a load as the conditions of station working allowed us to put on them. The feed pumps ran without the least trouble. The circulating pump engine did not run so satisfactorily; it seemed to be somewhat too small for its work.

We observe that in Nos. 3 and 4 machines a metallic shield has been inserted as a protection of the field winding from the armature coils. This is a very important improvement in the design of the alternators.

On the whole matter of the running plant in the station it gives us pleasure to say generally, in conclusion, that as to output, efficiency, and economy, as well as in respect to general construction, the results are very satisfactory, and are substantially in accordance with the conditions of the specification.

COMPANIES' MEETINGS AND REPORTS.

DIRECT UNITED STATES CABLE COMPANY, LIMITED.

The report of this Company for the half-year ended December 31 states that the revenue, after deducting out-payments, amounted to £43,938, as compared with £38,342 for the corresponding period of 1894. The working and other expenses (including income tax, but exclusive of cost of repairs of cables) amounted to £19,058, leaving a balance of £24,880 as the net profit, making with the balance brought forward a total of £26,290. For the corresponding period the working expenses and other payments amounted to £19,024. Interim dividends of 2s. per share for the quarter ended September 30 and of 2s. per share for the quarter ended December 31 have been declared, and, after setting aside £10,000 to the reserve fund account, the balance of £4,148 on the revenue account has been carried forward. During the half-year repairs of the cables, including provision to December 31 for operations not yet fully completed, have cost £6,984, which has been debited to the reserve fund account as heretofore, the balance of which, with the addition of interest and the amount set aside from revenue account, now amounts to £306,005.

CITY AND SOUTH LONDON RAILWAY.

The accounts of the City and South London Railway Company for the half-year ended December 31 show a balance, after providing for the debenture interest and the full dividend on the 5 per cent. preference shares, sufficient to allow the payment of a dividend on the consolidated ordinary stock at the rate of 1¼ per cent. per annum, carrying forward a balance of £1,220 to the new account. The dividend for the corresponding period last year was at the rate of 1¼ per cent. per annum, the balance carried forward being £950.

NEWCASTLE-UPON-TYNE ELECTRIC SUPPLY COMPANY, LIMITED.

Directors: Alderman T. G. Gibson, J. P. (chairman), Dr. Robt. Spence Watson, Dr. J. T. Merz, Colonel F. F. Sheppee, J. Tennant, Esq., J. H Armstrong, Esq.

Report of the directors to the eighth general meeting of the shareholders:

The directors have pleasure in presenting the balance-sheet and profit and loss account for the year ending December 31, 1895, from which it will be seen that the demand for electricity has con-

Digitized by Google

siderably improved during the past 12 months, the units sold having been 448,832 against 401,066 last year. The expenditure on capital account has been increased during the year by a portion of the cost of reconstructing one dynamo, so as to largely augment its output, and by the general extension of mains It has become necessary to extend the buildings, and additional plant has been ordered so as to meet the increasing demand for current. This will be fixed and in working order before the next winter's lighting season. To meet this expenditure a further issue of share capital has been made during the year, amounting to £6,725, of which a portion has been paid up and utilised in the extensions of the past year, and the remainder will be called up as required. The profit for the year is £2,909. 17s. 4d., as compared with £1,632 10s. in 1894. This profit is, however, chargeable with special adjustment of stock-taking and part of the expenditure on alterations to one of the dynamos, etc., amounting to £659. 6s. 5d., leaving a net balance of £2,250. 10s. 11d. Adding thereto the balance of profit brought forward from last year—viz., £288. 4s.—the total available profit is £2,538. 14s. 11d. Out of this the directors have transferred to reserve account a sum of £904. 3s. 7d., thereby increasing that account to £1,304. 3s. 7d., which they propose to use in further reducing the balance outstanding on the capital expenditure suspense account, so as to meet the views of the Board of Trade referred to in the directors' report for 1894. The capital expenditure suspense account will thus be reduced to £700, which which will be provided for out of the current year's profits. An interim dividend at the rate of 4 per cent. per annum was paid for the half-year ending June 30, 1895. The directors now recommend the payment of a dividend at the rate of 5 per cent. per annum, less income tax, for the half-year ending December 31, 1895. This will absorb £835. 3s., and leave a balance of £183. 18s. 11d. to be carried forward to next year's accounts. The retiring directors are Dr. R. Spence Watson and Mr. James Tennant, who are eligible and offer themselves for re-election. The auditor, Mr. Thomas Harrison, also retires, and is eligible for re-election.

BALANCE-SHEET, DECEMBER 31, 1895.

Capital and Liabilities.				£	s.	d.
Nominal capital—10,000 shares of £5 each				50,000	0	0
Issued and allotted—8,276 shares, with £4 per share called up	£33,104	0	0

CONTRACTS FOR ELECTRICAL SUPPLIES.

CONTRACTS OPEN.

Parma (Italy).—The municipal authorities of the city of Parma desire tenders by February 25 for the electric lighting of the city from June, 1897, to 1912.

Cattowitz.—Tenders are invited by January 29 for the supply of carbons for arc lamps at the railway. Particulars from the Königl. Eisenbahn-Direktion (Room 7 of the Administration Building), Cattowitz, for 50pfg. (6d.).

Aussig.—The communal authorities propose to have built a seven-mile single-line tramway. The choice of system is left open. Contractors are invited to place themselves in communication with the Stadtrath, Aussig-a.-d.-Elbe, Prussia. Tenders are to be in by January 31.

Swadlincote.—The Swadlincote Urban District Council intending to light the township of Stanton with electric lighting, invite tenders for the work. All particulars can be obtained from Mr. R. Cartwright, surveyor, Swadlincote, to whom tenders must be sent by 27th inst.

Chester.—Messrs. Thos. Parker, Limited, electrical engineers, Wolverhampton, request firms who are willing to tender for the buildings required for the electric lighting station in Chester to send in their names to Messrs. J. H. Davies and Sons, architects, 24, Newgate-street, Chester.

Wigan.—The Corporation invite tenders for the erection of a dynamo-house and boiler-house for the generating station of the proposed Corporation electric lighting works, for the Gas and Electric Lighting Committee. Drawings may be inspected, and copy of specification, conditions of contract, and bills of quantities obtained, on depositing £2. 2s., which will be returned on receipt of a bona fide tender, on application to Mr. Jos. Timmins, engineer, Wigan. Tenders, sealed and endorsed "Dynamo-House, etc.," to be addressed and delivered to Mr. J. J. Charnock, town clerk, by 20th inst.

Birkenhead.—The Corporation invite tenders for the wiring of the town hall in order to light the same by electricity. Plans can be seen on and after 15th inst., and a copy of the general conditions and specification, with form of tender, can be obtained on payment of £1. 1s. (to be returned on receipt by the Corporation of a bona fide tender) at the town clerk's office, Town Hall, Birkenhead, or at the office of Mr. James N. Shoolbred, M.I.C.E., 47, Victoria-street, London, S.W. Tenders, which must be on the prescribed form, sealed, and endorsed "Tender for Electrical Wiring, Town Hall," must reach Mr. Alfred Gill, town clerk, Town Hall, Birkenhead, by 12 noon on 23rd inst.

Shoreditch (London).—Tenders are invited for the supply and erection of buildings, including an engine-house, offices, and building enclosing dust destructor (the dust destructor being included under another contract), for the Vestry of St. Leonard, Shoreditch. Specifications, bills of quantities, and forms of tender, and any additional information can be obtained from the engineers, Messrs. Kincaid, Waller, and Manville, of 29, Great George-street, Westminster, S.W., on payment of £3. 3s., which sum will be returned when a bona fide tender is received by the Vestry. The plans can also be inspected by intending contractors at the offices of the

Digitized by Google

engineers. Sealed tenders shall be sent to Mr M. Mansfield Robinson, Shoreditch Town Hall, Old-street, E C., endorsed "Electric Light Station, Tender for Buildings," at or before noon on 20th inst. The contractor whose tender is accepted shall enter into a formal contract under seal with sufficient sureties for the fulfilment of contract.

RESULTS OF TENDERS.

New Mar (N.B.).—The tender of Messrs. P. C. Middleton and Co. for lighting and heating Mar Lodge by electricity for £3,000 has been accepted.

BUSINESS NOTES.

Neston.—The District Council have postponed the question of lighting the district by electricity.

Western and Brazilian Telegraph Company.—The receipts of this Company for the past week were £2,664.

Dover.—The electric light company are about to lay mains in Worthington-lane, York-street, and Priory-street.

Birkenhead.—The Town Council are lighting the town hall with electricity; the total cost is estimated at £1,500.

Monmouth.—The plans and specifications of the electric lighting scheme have been sent to the Board of Trade for approval.

Aberdeen.—The Lighting Committee have decided to erect about 230 additional lamps in the streets at a cost of about £4,000.

Kirkcaldy.—The Town Council have appointed a committee to consider the question of introducing the electric light into the town.

Minster.—The Isle of Thanet Rural District Council are making enquiries as to the cost of lighting the union workhouse by electricity.

Telephone Extension in Cornwall.—Active steps are being taken to obtain an extension of the Government telephone trunk line to Penzance.

Newport (Mon.).—The Town Council have decided to borrow £12,000 additional capital for extension of electrical plant, etc., making £40,000 in all.

Appointment.—Mr. J. F. Poynter, of 15, Seething-lane, E.C., has been appointed sales representative of the Cruto Incandescent Lamp Agency, Limited.

Bath.—It appears from the report of the Municipal Buildings Committee to the Town Council that the cost of the electric lighting installation was £786.

Ilfracombe.—The gas company's new Bill proposes to enable the company to apply for a provisional order to supply electricity within the limits of their gas supply.

Watford—The Urban District Council have unanimously resolved to appoint a committee to consider the advisability and practicability of lighting Watford by electricity.

New Cables.—The treaty of commerce between Chili and Brazil has been signed by the Presidents of the two Republics, and a cable is to be laid between Valparaiso and Punta Arenas.

Lighthouse Communication.—Maplin Lighthouse has just been connected by telephone cable across the sands 15 miles to Southend Coastguard Station for coast defensive purposes.

City and South London Railway.—The returns for the week ended January 12 were £1,020, compared with £1,001 for the corresponding period of last year, being an increase of £19.

Kingswood.—The Urban District Council have passed a resolution approving of the tramways company applying for an order legalising the late extension from the King's Arms to Warmley Hill.

Perth.—A committee has been appointed to consult with an expert as to what extent the lade power in the control of the Corporation could be used to light the Corporation buildings with electricity.

Train Intercommunication.—The agent of the South Indian Railway has obtained the sanction of Government for the introduction of Mr. Winter's electric system of train intercommunication on that line.

Pembroke.—It is stated that the old works of the Milford Haven Shipbuilding and Engineering Company at Jacob's Pill, Pembroke Dock, have been taken by a firm of electrical engineers, and will be opened shortly.

New Companies.—During the past year 3,540 new electric companies were formed, with a capital of £2,773,100, as compared with 2,668 companies (£2,387,107 capital) in 1894, and 2,333 companies £2,045,500) in 1893.

Liverpool Overhead Railway.—The traffic receipts of this railway for the week ending January 12 amounted to £1,120, as compared with £866 in the corresponding week of the previous year, being an increase of £254.

Sheffield.—A sub-committee of the City Council has been appointed to confer with the promoters of the Sheffield District and Rotherham Tramways Bill as to the provisions of the Bill, and report to a future meeting of the Parliamentary Committee.

La Compagnie Urbaine.—A general meeting of La Compagnie Urbaine d'Eau et d'Electricité has decided on an increase of the capital from 300,000fr. to 700,000fr. It is believed to be the intention of the Company to buy up a large number of smaller undertakings in France.

Cork.—Messrs. J. Furlong and Sons have offered to supply the electric current for one month free of charge at the South Jetties, for the purpose of lighting the place, as an experiment. The Harbour Board have accepted the offer, and passed a vote of thanks to Messrs Furlong

The Dangerous Trades Committee.—Commander Smith, R.E., Heatherley, Sheffield (secretary of Mr. Tennant's committee for enquiring into dangerous trades), will be glad to have the names tendered of persons desiring to give evidence with reference to electric generating works, etc

Bristol.—The Electrical Committee have decided to obtain an additional alternator, in order to efficiently meet the increasing demand for light, and to extend the mains from St. Stephen-street along Quay-street to Nelson-street. During the last month 1,400 new lamps were supplied with electricity for private consumers.

Ballochmyle (Ayr).—The sandstone quarries have been lighted by electricity to allow of work being carried on day and night. The order for plant and machinery was placed with Messrs. Paterson and Cooper, of London and Glasgow, and erected under the superintendence of Mr. E. George Tidd, M.I.E.E., A.M.I.C.E.

Yarmouth.—The borough surveyor's report on electric lighting states that the income for the year had been £1,942, leaving £463 towards repayment of capital, interest, depreciation, rates, and taxes, which he estimates would be about £900. The cost of the installation to the ratepayers in this the first year of working has thus been about £450.

Fermoy (Ireland).—The Town Commissioners recently advertised for tenders for lighting the district by electricity, but they received no replies. Mr. Warden Stevenson, electrical engineer, has written to them attributing that to the fact that it had not been mentioned in the advertisements that all information could be obtained at his office. It has now been decided to use incandescent gas-burners.

Bangor (N. Wales)—The City Council have decided to provide an electric lighting plant for the borough at a cost of £13,000. The British Insulated Wire Company, Limited, and the Manchester Edison-Swan Company, Limited, wrote offering to purchase the rights of the Council for generating and supplying electric energy, but the Council have replied that they have no intention at present of disposing of their rights.

Dublin.—The Corporation and the Dalkey Township Commissioners have decided to oppose the Dublin Southern District Tramway Company's Bill in Parliament. A long statement has been published by the managing director of the company to show that the extension of the lines into unoccupied parts of the city, and the introduction of the overhead system of electric traction, will be of great advantage to the town of Dalkey and the city of Dublin.

Tanfield (Durham).—The District Council are proceeding with the lighting of the district. Sixteen lamps have been erected at Hobson Colliery, and on Monday night the village of Tanfield was lighted. The contractors for the lamps were Messrs. T. A. Moffit and Co., Gateshead, who have been entrusted with the most of the lighting in the neighbourhood, and it was carried out under the superintendence of Mr. R. Heslop, surveyor to the District Council.

Birmingham.—A memorial signed by 6,300 people in Nechells has been presented to the City Council in support of the application of the Central Tramways Company for permission to adopt the overhead electric system on the Nechells route. Four memorials against the proposal were also presented. The first bore 727 signatures, the second 792, the third 1,063, and the fourth 975. The memorials were referred to the Public Works Committee.

Glasgow.—The Tramways Committee report that the electric light in the cars has been, for the time being, a failure. The contract with Froggatt's Electric Lighting Company had not been very satisfactory, and they had just received intimation that the company, who were the contractors for the lighting of the cars by electricity, were now in liquidation. The committee will now consider the propriety of having an electric light installation of their own for the cars.

Shoreditch (London).—The Electric Light Committee of the Vestry have had under consideration the question of entering into a contract to supply the London, Walthamstow, and Epping Forest Railway Company with electricity for lighting their stations and tunnels. The company would require about 420,000 Board of Trade units per annum. It was decided to enter into a contract with the company, whose trains, however, will not be running for another two years.

Worcester.—The quantity of water pumped by the electrical motors at the waterworks for the quarter ended September 29 was 15,237,500 gallons at a cost of £106. 19s. 8d. It was stated at the City Council meeting that the cost of pumping by steam power would have been about one-half that sum, but it was pointed out that last year was the driest year they had had for 81 years, and two turbines had been out of order for at least six months of the year.

Portsmouth.—The Provincial Tramways Company are promoting a Bill in Parliament for power to establish an electric tramway system. The project meets with the approval of the Corporation, and one object of the company in seeking this power is to meet the Corporation in their endeavour to utilise the current which now runs to waste at their electric light generating station. The company are also applying for power to erect generating stations of their own.

Digitized by Google

Gas in the City of London.—A deputation from merchants in Lime-street, headed by Mr. Thomas Christy, attended a meeting of the City Commissioners of Sewers, and drew the notice of the Commission to recent alarming gas explosions there. Such was the inconvenience created by these mishaps that, for fear of explosion, the inhabitants had not dared to light a match, or a candle, or their gas-burners for a week. The matter was referred to the Streets Committee for instant investigation.

The Electric Light in Hyde Park.—We are informed that, by order of the First Commissioner of her Majesty's Works, etc., an arc electric light has been placed experimentally opposite to the Marble Arch within the park. This has been done after consultation with the police authorities. Should the light prove a success it is proposed to light with similar lamps the footpath between the Marble Arch and Albert-gate, a much-frequented route, and also to place another row of lamps round the bandstand for use during the summer months.

West Riding.—The joint committee have had under consideration the question of a private service of telphones for the purposes of the West Riding Constabulary, and have instructed the West Riding solicitor to prepare an agreement with the National Telephone Company, Limited, embodying terms which include the payment of an annual sum of £1,300 by the County Council, the Telephone Company providing telephone communication for the West Riding police and sectional stations, to be connected by telephone with the headquarters at Wakefield.

Southport—The loss to the borough on last year's electric lighting is about £210. In making the installation the sum of £39,550 was spent upon private lighting, and £2,581 for the lighting of Lord-street and the promenade. There remains an unexpended balance of £691 upon the present borrowing powers, and it is intended to apply to the Local Government Board for power to borrow another £4,000 to light London street and Chapel-street by electricity at an estimated cost of £90 per annum. It is believed that in a short time the installation will pay its way.

Wimborne.—The Urban District Council have received a letter from the solicitors and agents of the Pokesdown Urban District Council as to opposing the Bournemouth Gas and Water Company's Bill in Parliament, it being pointed out that the company would acquire powers to supply gas, water, and electric light to the exclusion of the local authority. It was stated that the Pokesdown Council contemplated opposing the Bill, and as the Wimborne Council were affected in the same way, the solicitors asked if they would join with them. The matter has been referred to committee.

Ambleside.—The Electric Lighting Committee have intimated to the District Council that they have had under their consideration the application by the Windermere and District Electric Supply Company, Limited, for a provisional order authorising them to supply electric light within the district. The committee have conferred with the Board of Trade upon the subject, and have received an intimation that if they wish successfully to oppose the granting of the provisional order, it will be necessary for the Council themselves to apply for a similar order within a reasonable time.

Bradford.—The Gas and Electricity Supply Committee recommend the provision of additional engines and plant at an estimated cost of £11,000. The scheme of extension is expected to cost altogether a sum of £30,000. The plant will be of the best description and as a beginning two engines of 600 h.p. each and two dynamos will be fixed It is intended to put the Corporation in a position to supply electricity not only for lighting purposes, but for motor purposes. The charge for electricity for motive power is fixed at 3½d. per unit, and for electricity for lighting at 5d. per unit.

Birmingham.—Messrs. Lane and Martineau had given notice that they intended to propose resolutions at the Town Council with reference to the transit of mechanically-propelled vehicles along the public roads. Mr. Lane, however, withdrew his resolution in favour of Mr. Martineau's, which was as follows: "That a memorial to the Board of Trade be prepared and signed by the Mayor, in the name and on behalf of this Council, praying that a Bill may be brought in to relax the restrictions which now hamper the transit of mechanically-propelled vehicles along the public roads" The resolution was seconded by several members, and unanimously carried.

Messrs. Bennett and Druce.—This firm report from 30, Winckley-square, Preston, a moderately busy year, but the outlook is a good one. Some of their more important installations during the year have been St. Joseph's Catholic Church, Preston (battery and gas-engine installation); an installation of 600 incandescents and arc lights combined for the new sheds at the Salford Docks; the lighting of the late Colonel Ormrod's mansion at Scorton (steam and battery plant); the fixing of two electric motors for printing the *Preston Herald*; a 10-h.p. hoist for the Preston Industrial Co-operative Society, Limited; and also an electric heating and ventilating system for the same society.

Newington (London).—A petition is being signed in Newington, to be presented to the Board of Trade, in opposition to the Vestry's proposal to obtain a provisional order for electric lighting purposes. The petition points out that the parish mainly consists of small tenement and dwelling houses inhabited by two and more families; that there are no factories in the parish which would be likely to require electricity; and that there are but few main thoroughfares in the parish, and these of a character where electric light would not be needed by the tradesmen. These and other reasons are set forward, and the petitioners ask the Board of Trade to refuse their sanction to the order.

Aberdeen.—The Great North of Scotland Railway Company have decided on experimenting with the electric light for the illumination of their carriages on the system of Messrs. J. Stone and Co., Deptford, which has already been adopted by several of the English and Irish companies. At first the experiment will be confined to seven carriages comprising the suburban trains from the city to Dyce. Messrs P. C. Middleton and Co., electrical engineers, have received the contract for the lighting and heating of Mar Lodge by electricity. The electricity will be generated by water power on the estate, and the cost of the work is estimated at between £2,000 and £3,000

Hanley.—The Local Government Board have sanctioned the borrowing by the Council of the sum of £19,000 for the purposes of electric lighting. The Council have made a reduction in the charge for electric current. They have also resolved that a representation be made to the Board of Trade objecting to the North Staffordshire Tramways Company obtaining power to supply electrical energy for private purposes within the borough without the consent of the Council. The managing director of the company (Mr. Carruthers Wain) has written to say that this proposal of the company did not apply to Hanley, but to the other towns in which the authorities did not provide electrical power.

Eccles.—The Town Council have issued a statement on the subject of electric lighting to the ratepayers. The Town Council have received a letter from the Town and Village Electric Light and Power Company, Limited, stating that the company were prepared to erect on land owned by the Corporation a complete installation for public lighting by electricity, and to lay mains for private lighting on terms of an annual payment extending from 20 to 40 years, bearing interest at 3 per cent, so that the Corporation would, at the end of the term, acquire the whole property in an electric lighting installation in complete working order, as the company would maintain the installation, do the repairs, and effect the renewals by agreement.

Fareham.—In reference to the purchase of the electric light works, in accordance with the result of the poll of the ratepayers, the clerk has informed the Urban District Council that in accordance with instructions he had written to Mr. Whitlock, solicitor to the electric light company, to the effect that the Council accepted the offer of the company made in court to carry out their contract of August 16, 1894, in lieu of the payment of damages, and the company had replied offering to send a draft agreement, and to consent to a stay of execution of their judgment obtained against the Council. After discussion, it was decided that the matter should be deferred until the Council obtained a further report from their solicitors.

Ashton-under-Lyne.—The Electric Lighting Committee have ordered enquiries to be made by advertisement and circular as to the probable demand in the event of their carrying out the Electric Lighting Order of 1882. The sub-committee of the Highways and Tramways Committee reported that after a conference with neighbouring local authorities it was decided that the authorities should place themselves in a position to oppose the application of the British Electric Traction (Pioneer) Company, Limited, for powers to construct electric tramways from Oldham, through Ashton and Audenshaw, to Denton and Hyde, if such opposition should hereafter be found to be desirable, and the town clerk was instructed to take such steps as might be necessary for this purpose.

Halifax.—The Tramways Committee of the Town Council have decided to recommend the Corporation to approve of the Bill promoted by the Halifax and District Tramways Company, Limited, on condition that clauses are inserted for the protection of the Town Council with regard to gas and water pipes, electric mains and sewers. In their resolution the committee also suggest that the period for compulsory purchase of the tramways by the Corporation be reduced from 28 to 21 years, the term prescribed by the Tramways Act of 1870, in the event of the company's receipts showing an average dividend for the 21 years of 7½ per cent. The Sowerby Bridge District Council also, to whose district the proposed line of the company is to extend, have passed a unanimous resolution approving of the scheme.

Appointments Vacant.—The Lighting Committee of the Wolverhampton Town Council invite applications for the post of assistant and draughtsman to the borough electrical engineer at a salary commencing at £100 per annum. Candidates must have had training in mechanical and electrical engineering and be competent draughtsmen. Applications, to be made upon forms to be obtained from Mr. F. Harman Lewis, borough electrical engineer, Town Hall, Wolverhampton, to whom they are to be returned, duly filled in, with copies of testimonials attached, by 23rd inst.—The Government of Queensland, Australia, are prepared to receive applications for the post of electrical engineer to the Government at a salary of £600 per annum. Full particulars can be seen in our advertisement columns.

Witton Gilbert (Durham).—The lighting of the streets and roads of Witton Gilbert by electricity was formally inaugurated on Saturday. This installation has been erected by the Corlett Electrical Engineering Company, Limited, of Newcastle, Wigan, and Lancaster A coupled high speed vertical engine by Ruston, Proctor, and Co, Limited, Lincoln, drives a Crompton 250-volt dynamo which supplies current to about 180 16 c.p. lamps distributed over about 10 miles of wire, the furthest light being over two miles from the dynamo. The light having been switched on by Mr. Brass chairman of the Witton Gilbert Council, the whole body of councillors drove over the district and inspected the light, which gave great satisfaction, it being as bright and powerful at the most distant lamp as it was near the dynamo.

Digitized by Google

Copper.—The latest mail reports from America estimate that the consumption of copper has inproved at least 25 per cent. or more the past year than for 1894 Notwithstanding production increased and exports decreased, tabulated, yet the consumptive demand improved to such an extent as to absorb the increased surplus. Besides this a large amount of copper exported from this country during the year was reshipped back again for use here. It is confidently expected that the demand will greatly increase in the ensuing year, in anticipation of a largely increased demand for electrical purposes, as well as for general use The average price of Lake ingot copper at New York during 1895 was 10·77 cents per pound, while the average price of spot G.M.B. copper in London for the same period was £40. 7s. 4d. per ton.

Electric Lighting in the Metropolis.—The establishment of public electricity supply works in the metropolitan districts is a question that is now being prominently pressed forward by the various local authorities. Works are in operation at St. Pancras, Hampstead, and Ealing, and the Islington Vestry works are announced to be ready for opening on March 4. The Battersea Vestry have taken the novel course of offering premiums to consulting engineers and contractors for the best schemes, reports, designs, plans, and estimates for lighting the parish. the schemes to be submitted to an engineer of eminence for an independent report. In response to the invitation 21 schemes have been sent in, and they are now under the examination of Mr. Robert Hammond, M.I E.E., of London, who has been appointed the Vestry's electrical adviser on the subject.

Calendars.—We have received a well-designed calendar from Messrs. Ernest Scott and Mountain, Limited, electrical and general engineers and founders, of Newcastle-on-Tyne. The Sandycroft Foundry and Engine Works Company, Limited, have sent us their large office calendar. The sheet for each month contains a couple of illustrations of their manufactures; for instance, an electromotor driving a pump and an electric locomotive. From Messrs. Engelbert and Co, lubricating oil manufacturers, comes a large office calendar printed in colours. The feature of it is that each sheet contains the calendar for the month and also the year, so that back dates can be recovered after the sheets referring to the past months have been torn off. There has also to be acknowledged from the Chloride Electrical Storage Syndicate 16, Victoria-street, S W., a small waistcoat-pocket memorandum book. This is in addition to the annual pocket catalogue, and, like it, is a neat little book bound in red morocco

Ipswich.—On the report of the special committee on electric lighting coming up for discussion, the Town Council decided to withhold assent to the application for a provisional order by the County of London and Brush Provincial Electric Lighting Company. The decision practically stands by itself, and settles nothing, except that this particular order shall not receive the sanction of the Corporation. Beyond this everything is left open The committee appointed to consider the matter have been empowered to again consult Prof. Kennedy, and so far as the character of their report goes, they will have a free hand. About five years ago the Town Council decided that it would be best for the town to let some private company undertake the work, and they allowed a company to apply for a provisional order, and a fortnight after they allowed another company to do the same But this policy has now been reversed so far as the committee's report is concerned The number of private installations existing in the town may be taken as an indication that there is a real demand for electric lighting.

Derby.—The Bill to incorporate a company for the construction of tramways from Derby to Ashbourne has been deposited for next session. The Bill proposes to confer powers to construct a practically single line of tramway, commencing by a junction with the existing lines of the Derby Tramways Company in Ashbourne-road, Derby, and terminating in Ashbourne at a point near Compton Bridge. The capital proposed to be raised by the company is £70,000, divided into 7,000 shares of £10 each. Borrowing powers are also sought to be exercised by mortgages upon the undertaking to an extent not exceeding £17,500. By Clause 81 of the Bill it is provided that the cars shall be "moved by animal power," but every provision is made in the Bill to obtain the consent of the Board of Trade to the use of the "overhead trolley system of electrical traction," or some other mechanical power In addition to the carriage of passengers, the Bill provided for the carriage of animals and goods. The time sought for the construction of this tramway is five years from the passing of the Act, during which period it is proposed to pay interest out of capital to an extent not exceeding £10,000.

Swansea.—The Town Council have passed the formal resolution authorising the electric lighting and tramway scheme. In moving the resolution the Mayor (Mr. Bradford) said it would be remembered that the Council in committee had decided to call in independent expert evidence on the electrical scheme of Mr Manville, and he (the mayor) had since seen in London Mr W. H. Preece, electrician to her Majesty's Government in the Postal Department, and that gentleman had consented to examine and report thoroughly on Mr. Manville's plans and advise the Corporation thereon. Mr. Preece was one of the most eminent electricians of the day, and, although entitled to large fees, had kindly consented, under the circumstances, to accept only 100 guineas for his services, and he (the mayor) felt sure the matter could be safely left in his hands. Mr. G. Ellis, chairman of the Portsmouth Corporation Electric Lighting Committee, has written to the *South Wales Daily News* in reference to statements made by the opponents of the Swansea scheme that the cost of production of electricity in an ordinary electrical station with a lighting load only is 4d. per unit. At Portsmouth, Mr. Ellis remarks, the costs of production, inclusive of everything, are only 2¼d. per unit, whilst at Swansea, assuming that electricity was to be applied for lighting only, the cost would be slightly less, as coal is cheaper and of better quality.

Brighton.—Mr. Arthur Wright, the borough electrical engineer, suggests an extension of the electric lighting in the streets of 10 sets each of five seven-ampere lamps, such as are now being erected in the principal streets. The average distance apart will be about 70 yards. For the better lighting of the remaining streets he urges the committee to instal incandescent lamps in all the street lanterns that are in proximity to the distributing mains, his chief reasons being that the increased illumination of the streets can be more economically effected by using electricity than by increasing the consumption of gas, and that a profit of about £1,200 per annum would accrue to the Corporation by the electricity undertaking supplying the necessary current on the present tariff. The number of street standards affected by the proposed change of illuminant is at present 589. Mr. Wright estimates the capital required on district fund account at £4,300, and the capital required on electricity works account at £4,100. The Lighting Committee recommend that he be instructed to prepare specifications upon which tenders may be invited for carrying out the several works by contract. The committee further recommend that application be made to the Local Government Board for their sanction to the borrowing of the necessary capital. An installation is being fitted at 142, Marine parade, under the superintendence of Mr. W. Perren Maycock, M I E.E.

Edinburgh.—Mr. Mackenzie, convener of the Electric Lighting Committee, stated at the Council meeting that he had a report from the resident engineer showing that up to December 26 the units sold were 459,282, representing an increase of 73,282 units and £1,400 or £1,500 in money more than was expected a few weeks ago. With regard to a request by the treasurer, he could give an estimate of the cost of public lighting for next year on the number of lamps—250—sanctioned by the Council. Assuming that those lamps were all lighted for a year at the £18 rate proposed, the charge upon the Lighting Committee would amount to £4,500. They calculated that a capital expenditure of £12,500 had been incurred for the public lighting. The interest on that sum came to £375, or £1. 10s. per lamp; the sinking fund to £416. 13s. 4d., or £1. 13s. 4d. per lamp; the cost of carbons to £425, or £1. 14s. per lamp; the trimming to £750, or £3 per lamp; and the upkeep to £120, or 9s. 7d. per lamp. That left £2,413. 6s. 8d. or £9. 13s. 1d. per lamp for the current, and that meant that for the 480,000 units which they had to generate to keep the 250 lamps going for one year, they got about 1¼d. per unit. The Electric Lighting Committee have resolved to invite quotations from leading manufacturers for 10 000 high-voltage lamps, in view of the inauguration of the contemplated changes throughout the low-tension system from a voltage of 115 to one of 230.

Kidderminster.—The Kidderminster and Stourport Electric Tramway Bill has been deposited for next session. Upon this company power is proposed to be conferred to construct an electric tramway three miles six furlongs six chains in length, commencing opposite the Town Hall-buildings, Kidderminster, passing thence to Bridge-street, Stourport, opposite the north-eastern corner of the Bridge Inn. From this tramway two branch lines will run, one five furlongs in length, and the second four lengths seventy-one chains in length. In connection with these lines it is proposed to widen the two bridges which will be passed over in New-road, the two bridges which will be crossed in Stourport-road, together with a widening of that road on its western side. The period sought for the completion of these tramways is two years from the passing of the Act, or two years from the completion of any bridge or road widenings in the case of those lines dependent on the widenings. The capital of the company is fixed by the Bill at £60,000, divided into 6,000 shares of £10 each. The borrowing powers of the company are limited to £15,000, but it is expressly enacted that the company "shall not create debenture stock." The gauge of the tramways is to be 3ft. 6in., and, although the Bill contains a clause fixing the maximum rates for the carriage of goods, animals, and small packages, it is provided that the company shall not be bound to carry them between 8 o'clock in the morning and 8 o'clock in the evening.

Leeds.—The members of the Leeds Tramways Committee, accompanied by the city engineer (Mr. Hewson) have inspected a section of Mr. Chris Anderson's patent enclosed electrical conduit, which has been laid down for experimental purposes at Thwaite-gate, Hunslet. In this system the motors in the cars are fed from an underground conduit. Along the track, 21ft apart from each other, are iron boxes, the lids of which are level with the road. In each box are three pins, about an inch in diameter. These pins, by an ingenious mechanical arrangement, are made to rise about 3in. above the road as the car passes along the track. These small projections convey the current from the conduit to a collecting bar at the bottom of the car. At the end of the collecting bar is a ramp, or, in other words, the bar turns slightly downwards, and as the car passes over the ramp knocks down the pins to the level of the road again, and the current from that particular box is at once automatically switched off. The knocking down of these pins sends up the pins in the next box, which is then under the collecting bar right in front of the car. In the complete working of this system the current, after passing through the motors, is returned through the rails of the track. He estimates the cost of constructing his patent conduit at £1,200 per mile The committee have not yet come to a decision respecting this scheme. They were very favourably impressed with the Westinghouse electro-magnet system, of which they have seen a large working model at

Digitized by Google

Westminster, and they have resolved to recommend it to the Highways Committee.

Lambeth (London).—The Vestry have received a report from their clerk (Mr. H. J. Smith) that the London and Provincial Brush Electric Lighting Company had lodged a formal application for a provisional order for lighting the whole of the parish, as well as Newington, Camberwell, Battersea, and the district of St. Saviour's Board of Works. The order contained the usual provisions and provided for no limit of time, so that it would therefore be permanent subject to the power given by the Act of 1888 to the Vestry to purchase the undertaking at the end of the various periods set forth. As notice of objection must be lodged at once, the Vestry were advised to promise the Board of Trade to take up the order and begin work at once, or allow the company a free hand. Mr. Sydney Morse, on behalf of the Brush Company. wrote pointing out that his company were the undertakers in Wandsworth, and had a capital of £800,000. Mr. C. W. Sax, of 366, Central Markets, West Smithfield, wrote that he was prepared to take over the obligations of the order, and Mr. Stewart Bain, on behalf of the London Electric Supply Corporation, wrote requesting the Vestry not to assent to any application from another company. After a long and at times somewhat lively discussion, during which a motion and amendment were rejected, the Vestry decided to instruct the clerk to lodge an objection to the granting of any order to the company except on the condition that the order should not now apply to any of the areas now covered by electric lighting companies; that the time for compulsory purchase be made concurrent with that of the London Company; that the cost of light per unit should not exceed 6d.; that the company pay the Vestry £1 000 to cover the initial expenses incurred by them in obtaining their order in 1892; that the clerk should be instructed to oppose any order for the parish until the Vestry had decided to accept or refuse the offer of Mr. Sax or any other company who may offer within a month to take a transfer of the Vestry's order.

Plymouth.—The Electricity Sub-Committee have made the following suggestions to the Town Council: "That the Council should itself put in force the powers it has obtained for supplying electricity within the borough, and that the central station should be on the shores of the Cattewater, and should be so designed that the waste heat from a destructor may be utilised if hereafter found desirable or feasible, and that electricity for traction purposes should be supplied from the same station." They further recommended: "That an engineer should be appointed at a salary of £300 per annum, rising by four equal annual increments to £400 per annum, and that in this way the conmissions usually paid during construction should be saved, and the services of a competent man fully conversant with every detail of the undertaking and practically interested in it secured. That the Corporation should not tie itself at this stage to any consulting engineer, nor to any manufacturer, type of engine, or plant. That public lighting of the Hoe, the principal places of resort, and streets should be at once undertaken; and that, immediately upon his appointment, the electrical engineer, unfettered, except in so far as the above recommendations are concerned, should be instructed to prepare a scheme for supplying electricity for power and lighting, with a view to the same being submitted to the Council, and subsequently to the Local Government Board for approval, and for the sanction of the last named body to the necessary loan for carrying out the scheme if the Council should approve thereof" Mr. Willoughby, in moving the adoption of the recommendations, referred to Dr. Fleming's report, and added that, excluding places where cheap and nasty experiments had been made, he (Mr. Willoughby) had not succeeded in finding a failure on the part of any corporation that had adopted the electric light. Taken in conjunction with the service of tramways, it was most desirable that they should have the electric light. If from April to November last they had electric power for their cars, such as they saw in Bristol, they might have saved in 12 months—taking the average for the period named—nearly £4,000. Horse power cost them 10½d. per car per mile, whereas in Bristol the electric power cost 5d. If they could save so much under present conditions, they would save more if the lines were coupled up. A station both for lighting and power must reduce the cost of both. After some discussion an amendment, omitting the tramways portion of the scheme, was rejected by 25 votes to 12, and the report of the committee was adopted.

Messrs. E. Scott and Mountain.—This firm report from Newcastle that during the past year a large increase in the turn-out of plant for electrical transmission of power has taken place, and some important contracts for electrical pumping, hauling, winding, etc, have been completed. A large transmission of power plant has been shipped to South America. comprising two generating dynamos, two sets of winding gears with all requisite switches and other appliances, two electrically-driven fans for the workings, a set of electrically-driven air-compressors, and also pumping apparatus. This plant represents the transmission of about 160 h.p., and is considered to be one of the most complete plants yet supplied. In the Yorkshire and Lancashire districts a number of important installations have been fitted up for hauling, pumping, and coal cutting. For the Northumberland and Durham districts similar plants have also been supplied of equal and smaller powers, and for the Colonies a considerable amount of work has been done in the same direction. The generating dynamos constructed during the year for the transmission of power alone represents in the aggregate 1,000 h.p. to 1,200 h.p. Electrical coal-cutting has developed during the year, as many as six separate plants having been supplied to various collieries for this purpose. In their electric lighting department the firm have been very fully employed, many important installations having been fitted up both in the United Kingdom and abroad. The dynamos and motors comprise a large variety of sizes, varying from ¼ h.p. to 150 h.p. In addition to their standard type of dynamos and moters, the firm have introduced a special design of electrically-driven fan for ventilating on board battleships and merchant vessels. For the British navy these have been supplied and fitted on board H.M.S. "Juno," "Doris," "Venus," and "Diana. In ship-lighting the firm have also been busily engaged, and, in addition to a large number of installations which they themselves have carried out, they have supplied a large number of combined engines and dynamos to other contractors. In their engineering department they have not been any less busily employed, over 30 of their special high-speed engines having been supplied, representing a total of about 1,500 h p, these varying in size from 10 h.p. to 200 h.p. These engines are specially designed and built for driving electrical plants, and are made with single or double cylinders or of the compound type. The prospect of business in the near future is also good, as the firm at the present time are busily engaged, and have a very large number of orders still in hand in all departments. In their foundry department they have made considerable strides, and have been more fully occupied than in any previous years.

Newcastle-on-Tyne.—Before finally deciding on the adoption of the cable system for the Newcastle tramways, the Town Council decided, after a very long discussion, to send a large deputation, consisting of one-third of the members, to Bristol to make an inspection of the electrical tramways there. The deputation arrived at Bristol last Saturday, and were met at their hotel by Mr. George White, the managing director of the Bristol company, who furnished the members with a variety of details as to the working of the electric tramway, and many of the deputation availed themselves of the opportunity of an unofficial inspection the same night. On Monday morning the deputation were met by the Mayor of Bristol, on behalf of the Corporation, and Mr. George White, the managing director, and Mr. Samuel White, the secretary of the Bristol Tramways and Carriage Company, at the Royal Hotel, where a four-in-hand horse car was waiting, and conveyed them to Old Market-street. There a special electric car was in readiness, and the party proceeded over the whole of the line, and made a very complete inspection of the power station at St. George, where the tramway company's officials explained the details of the electrical equipment. After the return journey, the Mayor of Bristol, the Mayor and Sheriff of Newcastle, and the other members of the deputation were entertained by the directors of the company to luncheon at the Grand Hotel, Mr. William Butler, chairman of the company, presiding. In acknowledging the toast of "The Mayor and Corporation of Newcastle," the Mayor of Newcastle explained that their Corporation were now anxiously considering the merits of the systems of cable and electrical tramways, and he was bound to say that he and the other members of the deputation had been very much impressed with what they had seen in Bristol that day. Mr. Alderman Winter, in proposing "The Bristol Tramways and Carriage Company," said that having travelled over a large portion of the world, and therefore having seen a very large number of tramway undertakings, he was bound to express his admiration of the manner in which the Bristol tramways were managed. Mr. Low, a director of the tramways company, said the line they had inspected was authorised in the year 1891 for cable traction, and the company had gone to considerable expense in having plans and estimates prepared based on that system; but, after mature consideration, the directors unanimously felt that it would be unwise to enter upon such a form of construction, and a year or two since, after a complete examination of various electric tramways in important towns on the Continent, and by the aid of the best advice they could procure, they determined to adopt the electric trolley system. It was true that it had been working only three months, but they were perfectly satisfied that this system was the best which could possibly be adopted in the city, not only for the company, but for the travelling public, and they had already informed the Corporation of Bristol that they were ready to engage in the very large outlay which would be necessary (practically the doubling of their present capital) to extend the benefits of electricity to the remainder of their tramway system, and, in addition, the company were ready to extend the advantages of an electric tramway service to other districts which hitherto had been inaccessible to horse power. They hoped and believed that, as a result of the negotiations which they were about to enter upon with the Corporation, a very large extension of electric traction would take place in Bristol. The report of the Council was presented at a special meeting of the City Council on Wednesday. It recommended that application be made to Parliament for additional provisions to be inserted in the present Bill which would include the Westgate-road, Arthur's-hill, Elswick-road, Scotswood-road and Byker tramways within the power to work by electricity; and that in the meantime the whole question of dealing with the tramways of the city be referred back to the Town Improvement Committee. Sir Charles Hamond, M.P. moved an amendment to the report that the Bill be withdrawn from the present session of Parliament, and that the whole matter be referred back to the committee in order that they might decide which system was the better system for the Newcastle tramways This amendment was lost by 31 votes to 16, and the report was adopted by a majority of 1. A meeting of ratepayers was afterwards held. The Mayor proposed a resolution authorising the Council to promote the Bill. This was seconded by Mr. B. J. Sutherland, and after a heated discussion was declared lost on the show of hands. A poll was demanded, it is understood, by Mr. Frank Marshall, solicitor to the tramways company.

PROVISIONAL PATENTS, 1896.

JANUARY 1.

64. Improvements in or relating to electric tramways or railways. Francis Krizik, 433, Strand, London. (Complete specification.)

JANUARY 2.

94. An improved regulating and feeding mechanism for electric arc lamps. Harold Sisson Jacques, Municipal Offices, Cheltenham.

130. Improvements in and relating to electric accumulators. Robert Jacob Gülcher, 6, Lord-street, Liverpool. (Complete specification)

135. A new or improved method for the adjustment of carbons in electric arc lamps. Vincent Fabris, 64, Mark-lane, London.

JANUARY 3.

156. Improvements in regulating the supply of gas or electric light to railway coach compartments. Herbert Tatham Procter and Robert Edwin Gill, 154, St. Vincent-street, Glasgow. (Complete specification)

207. Improvements in electric arc lamps. William Phillips Thompson, 6, Lord-street, Liverpool. (The Electric Arc Light Company, United States.) (Complete specification.)

234. Cycles electrically driven by means of electricity collected from fixed conductors for track-pacing and other purposes. Robert Alfred Marples, Tyndale Lodge, Highland-road, Bromley, Kent.

JANUARY 4.

265. An improved reflector for electric glow lamps. Henry Nield Bickerton, 64, Barton-arcade, Manchester. (Complete specification)

270. Improvements in incandescent electric lighting apparatus. Sidney Harper Heywood, 5, John Dalton-street, Manchester.

306. Improvements in the manufacture of electrical hot-plates and other electrical apparatus for cooking and heating purposes. John Chambers, 7, Staple-inn, London. (Date applied for under Patents etc., Act, 1883, Section 103, November 8, 1895 being date of application in New Zealand)

308. Improvements in electric switches. Charles Solomon Newman, 226, High Holborn, London.

JANUARY 6.

342. A new or improved combined portable electric light and current generating apparatus. Joseph Rabitean Welland, 22, Glasshouse-street, Regent-street, London.

347. An improved switch for electrical purposes. Charles Bruce Wood, 97, Newgate street, London.

355. An electrical regulator for regulating arc lamps and for other purposes. Albert Lewis Davis, 28, Southampton-buildings, Chancery-lane, London.

JANUARY 7.

390. Improvements in electrical switches. John Theodore Leroux, 24, Temple-row, Birmingham.

434. New and useful phase-completing device. Theodore McKenna, 17, Basinghall-street, London. (Electric Selector and Signal Company, United States. (Complete specification.)

452. Improvements in apparatus for controlling electric motors. Henry Harris Lake, 45, Southampton buildings, Chancery-lane, London. (Bradley Allan Fiske, United States.) (Complete specification.)

474. An improved turning-plate for electrically or mechanically propelled vehicles. Walter Charles Bersey, 53, Chancery-lane, London.

475. Improvements in electric accumulators. Walter Charles Bersey, 53, Chancery-lane, London.

477. Improvements in electrical storage accumulators. Charles Nigel Stewart, 53, Chancery-lane, London.

JANUARY 8.

533. Improved automatic remontoir apparatus for Hughes's telegraph apparatus. Siemens Bros. and Co., Limited, 28, Southampton-buildings, Chancery-lane, London. (Siemens and Halske, Germany.)

535. Improvements in primary and secondary batteries. Henry William Headland, 77, Chancery-lane, London.

543. Improvements in or relating to means for producing differences of phase in alternating-current apparatus, specially applicable to meters, motors, and the like. Georg Hummel, 46, Lincoln's-inn-fields, London.

546. Improvements relating to electric incandescence lamps, and to adapter fittings therefor. Reuben James Bott, 11, Southampton-buildings, Chancery-lane, London.

547. Improvements in devices for joining or connecting electrical cables or conductors. Henry Edmunds, 47, Lincoln's-inn-field, London.

551. Improvements in dynamo-electric machines and motors. Llewelyn Birchall Atkinson, 1, Queen Victoria-street, London.

557. Improvements in electric batteries. Richard Collins and Frederick Cogan, 45, Southampton-buildings, Chancery-lane, London.

565. Improvements in apparatus for transforming continuous electric currents. Henry Harris Lake, 45, Southampton-buildings, Chancery-lane, London. (Cie. de l'Industrie Electrique, Switzerland.)

NOTES.

American Tramways.—The total length of the street railway lines in the United States equals 13,176 miles, of which 10,238 miles are run by electric power.

Trinity House.—The appointment of scientific adviser to the Trinity House, which has been in abeyance since the resignation of Dr. Tyndall, and which was formerly held by Prof. Faraday, has now been revived and conferred upon Lord Rayleigh.

Fatal Accident.—On Wednesday evening, Edward Clarkson, in the service of Messrs. Siemens Bros., electrical engineers, whilst at work at the lighting station at Hampstead, accidentally received the full force of the current, and was killed instantly.

Birkenhead.—We understand that the municipal authority, under the advice of their consulting engineer (Mr. J. Shoolbred), have adopted the higher pressure now permitted by the Board of Trade, and will be known to history as having been the first municipality to do so.

Obituary.—We regret to announce the death of Sir Henry George Calcraft, which occurred on Thursday afternoon at his residence in Mount-street, Grosvenor-square after a brief illness, from pneumonia. He was a director of the National Telephone Company, and till 1893 permanent secretary to the Board of Trade.

The South African Cables.—Last Monday the predicted breakdown of the two lines really occurred, the postal telegraph authorities announcing that the cables between Lourenço Marques (Delagoa Bay) and Durban on the East Coast and St. Thomas and Loanda (Angola) on the West Coast were interrupted, thus completely cutting off communication with South Africa.

Illuminated Life Buoy.—According to *Die Vedette*, a German naval captain has invented a new life buoy. It consists of a large cork ring capable of floating three persons. Its principal feature, however, is that it is fitted with an electric light, fed by a small accumulator which will store sufficient electricity to keep the lamp alight for 24 hours. That seems a most uncomfortably long period to remain in a life buoy.

Collectors' Lamps.—The ticket-collecting staff at the Vauxhall Station of the London and South-Western Railway have been fitted with the electric light. That is to say, they carry small electric lamps, which are fixed on their overcoats, the current being supplied from a miniature battery carried in the breast pocket. The experiment is to be tried for a month, and if it finds favour with the officials electricity will supersede the old-fashioned and somewhat cumbersome hand-lamp.

The "Swan" Fountain Pen.—Messrs. Mabie, Todd, and Bard, of Cheapside, have sent us one of their "Swan" fountain pens. To literary and to business men a really good and reliable fountain pen is of great value, and after a fair trial we have come to the conclusion that the "Swan" pen is one of the best of its kind. The nib is of gold, the ink flows freely, and the pen can be very easily cleaned when required. The price of the pen, including glass filler, is 10s. 6d.

King of the Belgians.—King Leopold, accompanied by the Belgian Ambassador, visited the works of the Waterloo and City Railway last week. After being clad in appropriate costume, his Majesty descended the shaft in the River Thames and was conveyed along the contractor's electric railway to the working faces at the City end of the railway, which have now reached a point in Queen Victoria-street, near St. Nicholas's Church. The party then returned towards Waterloo and inspected the working of the air-lock, the tunnels at this end of the line being driven under compressed air. His Majesty spent nearly an hour on the works.

Institution of Junior Engineers.—The eleventh anniversary dinner of the Institution of Junior Engineers will take place next Saturday at the Westminster Palace Hotel. The president, Mr. Archibald Denny, will take the chair, and will be supported by Mr. James Dunn, acting director of naval construction, Mr. A. J. Durston, C.B., engineer-in-chief of the navy, Sir Donald Currie, K.C.M.G., M.P., Mr. John M. Denny, M.P., Mr. E. Windsor Richards, Dr. John Perry, and Profs. J. Harvard Biles and Carlton J. Lambert.

Brooklyn Tramways.—According to the *Brooklyn Citizen*, Chief Inspector Franklin, of that city, has reported that the running time on some of the trolley roads has been reduced. As a result, the speed of the cars has been increased, and it is stated that in one case a car was seen going along Nostrand-avenue at over 24 miles an hour. Accidents have naturally resulted. Our contemporary urges that rapid transit is impossible on a street line of any description. It may not be impossible, but it is certainly undesirable.

Telephone to Berlin.—The *Financial Times* considers that the London and Paris telephone has been an immense success, but it has long been felt that it would be advantageous to have other Continental centres brought into vocal communication brought with our little village. In the German Reichstag Dr. Stephan, the Postmaster-General, has stated that it was intended to establish direct telephonic communication between London and Berlin. "The new departure," says our contemporary, "will be a boon to business men, and it will also be convenient for the German emperor whenever that potentate feels disposed to send lively messages to this country."

Accumulator Cars.—The Berlin-Charlottenburg Tramways are trying to solve the problem of electric traction on the accumulator system. A new type of car built for and now working on a section of this line carries 20 passengers in the interior and nine passengers on the platform, or with the motorman and conductor altogether 31 persons. The power is derived from a 124-cell Schäfer and Heinemann accumulator, arranged under the seats. This supplies current to a two-pole 18-h.p. motor, the potential being 250 volts and the current 60 amperes at 300 revolutions a minute. The intermediate gearing runs in oil. There appears to be no new principle involved in the construction, and the efficiency claimed can only be determined after a more extended trial.

Trans-Pacific Cable.—An Inter-Colonial Conference of Postmasters-General has been held in Sydney, N.S.W., concerning the appointment of Australian representatives on the Pacific Cable Commission to be held in London. Resolutions were adopted, subject to the approval of the Colonial Governments: "That a cable should be constructed and owned jointly by the various Governments interested. That the landing of such cable should be only upon territory belonging to or under the control of the British Empire. That the cost of construction, working, and maintenance be borne by Great Britain, Dominion of Canada, and the contributing Australasian colonies in proportion of one-third. That the route from Fiji to Australia be to Norfolk Island, and thence bifurcating to the nearest convenient landing places in North New Zealand and Moreton Bay respectively."

Dundee Mechanical Engineers.—Last week Mr. Henry Cameron lectured on "Friction" to the Dundee and North of Scotland Institute of Mechanical Engineers. Mr.

Digitized by Google

D. J. Macdonald presided. The lecturer stated that some time ago he made practical experiments with different kinds of metals, chiefly of the soft or white metal type, but of different compositions. The chief lessons he learned from the experiments were that there was not such a very great difference in the actual usefulness of soft metals of different compositions, and that those composed of the cheapest materials stood the test fully as well as those composed of the dearest; that those with a basis of lead stood as well as those with a basis of tin. The proportions were very elastic, as shown by the fact that in the German navy there was used a composition which was nearly all tin, and in the French navy a composition which was nearly all zinc.

North-East Coast Engineers.—At the fourth meeting of the present session of the North-East Coast Institution of Engineers and Shipbuilders, held in the hall of the Literary and Philosophical Institution, Newcastle, Mr. J. R. Fothergill, in the absence of the president, occupied the chair. A hearty vote of thanks was given to Mr. W. Cross for his paper on "Plant at the Newcastle and District Company's Electric Light Works, Forth Banks, Newcastle." Mr. J. Denholm Young's reply to the discussion on his paper "On the Application of the Law of Similarity of Marine Propellers" was read to the meeting by the secretary (Mr. John Duckitt), and a paper on "Counter-Sinking in the Shipyard" was contributed by Mr. Robt. H. Muir. An interesting discussion took place on Mr. J. M. Allan's paper on "An Investigation into the Forces Tending to Produce Vibration in High-Speed Engines." Part I. of the *Transactions* of the institution has been printed and issued to the members.

Goods Train Brakes.—The *Times* considers that it would be a desirable thing if continuous brakes were fitted to the goods trains on English railways. Neither the automatic vacuum nor the Westinghouse automatic brakes used in this country are suitable to very long trains, the distribution of pressure not taking place quickly enough. The brakes, therefore, may be hard on in the front of the train while unaffected in the back part, and the attempt to effect a rapid stop of a long train will certainly result in violent jerks. However, forms of brake have been designed which can quite well be used on the longest trains. The Westinghouse quick-acting brake, for instance, a modification of the ordinary Westinghouse, is extensively used on goods trains in the United States, while even quicker results might be obtained from an electrically-controlled apparatus, such as Carpenter's electro-pneumatic brake. As to the Chapsal electric brake, which some time ago was noticed in these columns as specially designed to meet the needs of goods trains, no further details as to its construction have up to the present appeared.

An American Invention.—Mr. E. B. Dunn, chief of the Weather Bureau in New York, has invented a system of alarm signals for the purpose of preventing rear-end collisions on railways. Wires are run along the telegraph poles and connected to the train despatcher's office. The poles carry a switch and a red lamp, and when a train is stopped the trainman is expected to go to the nearest telegraph post, probably in the dark, and by turning a switch light up all the lamps on the poles behind the train, as well as one in the despatcher's office. This would be a highly effective way of notifying to the public as well as the following train that an accident had occurred, if the trainman did not happen to be hurt in the accident and the apparatus had not got out of order, as emergency apparatus which are seldom used have a way of doing. In Great Britain, in a similar case, the guard simply takes the red lamps off the tail of the train and walks down the line with them as far as he thinks necessary, which ought to come to much the same thing. The mystery is why the Americans cannot adopt a block system and save all this invention. It might not be so pretty, but it would be certainly more effective than Mr. Dunn's electric signals.

Utilising the Scorcher.—In reference to an abstract of an article in *L'Etincelle Electrique* given by us under the above title we have received a letter from the Crypto Works Company, Limited, 29, Clerkenwell-road, pointing out that at the National Cycle Show held at the Crystal Palace towards the end of 1894 a front-driving safety bicycle arranged for driving a small dynamo was exhibited by them. The dynamo was used to supply current to some small fan motors, incandescent lamps, etc., but the idea really was that the arrangement could be used during winter months as a kind of home trainer, the dynamo acting as a brake to the wheel, and accumulators being charged by the current, to be afterwards used for night-light, reading-lamp, etc. The Crypto Company add: "We made a number of experiments, and found that a good rider could maintain an output of 50 watts practically for any length of time. The output mentioned in your note—viz., 140 watts—seems high; we do not think it could be kept up for sufficient time to be of real service." In this respect our correspondents are undoubtedly right; even if there were no waste of power, the output expected was obviously excessive. The article was noticed by us as being curious, but the idea was, of course, not a new one.

The Berrenberg-Chaplin Vacuum Pump.—A report by Prof. W. E. Ayrton, F.R.S., on the practical value of this pump, which we described in our issue of the 10th inst., has reached us. After a long and careful series of trials, Prof. Ayrton reports that the pump produced in 21 minutes a better vacuum than that found in any of the eight typical commercial lamps he tested. The time required for obtaining different degrees of vacuum was as follows: in $2\frac{2}{3}$ minutes the pressure in the bulbs was $\frac{1}{100000}$th of that of the atmosphere; in 15 minutes it had fallen to $\frac{1}{2500000}$th, and in 21 minutes to $\frac{1}{3333000}$th, as measured on a McLeod gauge. After testing the pump against a small leak in the system, and after admitting air to the cylinders, Prof. Ayrton concludes that the combination of pumps as erected at 4, Huggin-lane is capable, in 15 minutes, of creating a vacuum as good as that in the best, and much better than that in the worst, of the incandescent lamps he examined, and that it is capable, in 20 minutes, of creating a vacuum much better than that in any of the lamps broken under mercury; that the system of pipes, cocks, and glass stoppers is for all practical purposes perfectly air-tight; and that even should a small leak occur the pumps are able to work against it until it is remedied.

Bad Electric Lamps.—Correspondence and complaint on this subject still continues in the daily Press. What the *Daily News* had to say on the subject was dealt with last week. The *Daily Telegraph* now takes up the tale, the burden of the advice given being, "Don't buy cheap German electric lamps." Lamps which are short-lived are generally found to be those that are imported. One large firm, which acknowledges that even patriotism would not prevent its orders being placed in the cheapest market, declares that it has been impossible of late to accept even the best German incandescent lamps. The samples when tested prove themselves to be all that can be desired, but the goods, when once they come to hand, are not up to sample. Lamps which pretend to be of 23 c.p. have been revealed under the test as of 14 c.p. only, and it is inferred that this wide margin could not have been due to accident. Under the title of "The Life of a Charcoal Thread," the *Daily Chronicle*,

Digitized by Google

in endeavouring to make its readers understand the theory of the matter, becomes quite poetical. "There is, indeed," says our contemporary, "something about its glowing charcoal thread that touches us on the human side. We see it start its normal life of a thousand hours with the bright fervour of youth, then pass into the steady glow of maturity, finally enter on its decadence, old age, and ultimate death. Like the human organism, it may live its life too fast. If an excessive energy be passed through its mortal coil, the whole span of life will pass in a few minutes, even seconds."

University of London.—At the Society of Arts last week, Prof. S. P. Thompson read a paper on "The Making of a Great University for London." Lord Reay presided. Prof. Thompson said that the only really comprehensive scheme of reconstruction of the University of London was that of the second Royal Commission under Lord Cowper, which unanimously reported against the Gresham scheme. In condemning the constitution of the present university, he pointed out in the course of his lecture that in the regulations for the degree of Bachelor of Science not a line had been changed since 1876 in the syllabus of subjects for the examinations in such progressive sciences as chemistry and physics. No questions could be asked in chemistry about argon or helium, or even about so fundamental a topic as the periodic law. No questions could be asked in physics about the microphone or the phonograph, about alternating currents, or about Hertz's classical researches on electric waves. What they did not find in the text-books of 20 years ago was not science. At a university convocation on Wednesday a resolution proposed by Prof. Thompson, "That this house desires the early introduction into Parliament of a Bill for the reconstitution of the university similar to that introduced last year by Lord Playfair, but with an inserted clause ecuring to the senate, to convocation, and to other bodies affected the right of appeal to the Privy Council on any of the provisions which may hereafter be settled by the Statutory Commission," was carried by 466 votes to 240.

The Telephone in Colombo.—England is not the only country which suffers from unsatisfactory telephonic arrangements. According to the *Ceylon Times*, Messrs. Murray, Robertson, and Co., as agents of the local telephone company, have intimated to subscribers to the exchange that the telephone business hitherto conducted by them will be discontinued from December 31 last. The announcement is a rather sudden one, but the decision is the outcome of the threatened competition of Government through the Post Office. For two years negotiations have been going on between Government and the local telephone company, and the Telegraph Department would have before now taken over control of the telephone by buying up the existing service had the Government been willing to accede to the company's terms. Much correspondence was carried on, which was referred to the Secretary of State, and the company being apparently tired of it has decided to give up the field, and as nearly all subscriptions lapse at the end of the month, it was deemed desirable to close them. The matter has advanced but little at the Post Office, however, and there is a likelihood that Colombo will be without a telephone service for several months. The local Government has referred the matter to the Secretary of State to know whether better terms shall be offered for the existing service or whether new plant shall be got out from England. The company claim to have been badly treated, and they will now sell their business to the highest bidder.

Hertzian Waves.—In a review of the progress of electrical science during the past year, *L'Industrie Electrique* remarks that the work of Hertz lives after him and the subject of electric waves keeps still to the front. During the year their domain has been extended from the simpler cases to the elucidation of complex phenomena, and the parallellism between the electromagnetic undulations and light waves has been perfectly established. M. Lebedev has produced Hertzian waves of much smaller dimensions than heretofore obtained. Other investigators working on a larger scale have found clear traces of their double refraction in wood, the velocity of propagation being different across or along the grain. A similar effect has been obtained from dielectric media artificially arranged so as to have different properties along different axes, and the phenomena are clearly brought out in a cube composed of layers of paper. The phenomena corresponding to diffraction have hitherto been little considered, except that MM. Sarasin and de la Rive in their researches used a mirror of unusual dimensions in order to avoid its effect. The phenomena being, however, necessarily much feebler than those of the directly propagated wave, their observation is very difficult and uncertain with detectors dependent upon the completion of a spark in an incomplete circuit. The review also notices the discovery of Herr Aschkinass worked out by Herr Haga at Berlin and the Japanese Prof. Mizuno at Tokio on the effect of the waves on a sheet of tinfoil mounted on an insulating surface, and cut alternately from above and below so as to leave a number of strips, forming a long zig-zag of continuous material. The conductivity of the foil is lowered after being subjected to the action of the waves, but is brought back to its former value by a slight shock.

Theory and Priority.—Whatever may prove the practical results of Prof. Röntgen's discovery, an explanation of the nature of the new radiations would be of great interest in connection with the electromagnetic theory of light. Assuming them to be of the character of ordinary rays, they must be either above or below the known spectrum. There is plenty of room between the 6mm. electric waves of M. Lebedev and the infra-red spectrum, and there are strong theoretical reasons for seeking their place there. On the other side of the spectrum there is unlimited room, since there is no known limit to the smallness of a light-wave. This latter hypothesis is one that finds favour with Mr. Campbell Swinton. There are difficulties to be got over before either can be accepted. The hypothesis of the discoverer is even more difficult. This week's *Zeitschrift für Elektrotechnik* devotes a long article to what it calls "Prof. Röntgen's epoch-making discovery," and there states that Prof. Röntgen has adopted, though with reserve, the view that the radiations are "the long-sought longitudinal vibrations of the ether." Every man has a right to invent his own ether, but the main object has been hitherto to get rid of longitudinal vibrations. The point could be settled by any method that would give the rate of transmission. Meanwhile Prof. Röntgen is not to be allowed the credit of the discovery without challenge. Mr. Leslie Miller, A.I.E.E., writing in the *Photographic News*, claims the honour for Mr. Crookes. A very serious claim of priority has been made for the Hungarian Prof. Lenard based on a communication made by him to Poggendorf's *Annalen für Physik. und Chemie.* in 1894 with reference to photographs obtained from the cathode rays. If he did not make the actual discovery, he most nearly missed it. The claim of Prof. Zenger, of Prague, will hardly be treated so seriously.

Crookes Tube Radiations.—Mr. A. A. Campbell Swinton has lost little time before repeating in this country Prof. Röntgen's experiments in the new photography, and exhibited some of his results last week at the Camera Club. Mr. Swinton explained that he had been guided only by the

Digitized by Google

newspaper reports of the experiments of the Austrian professor, and that the work had been done hurriedly, and therefore he was not able to show results as complete as he could wish. What was called a Crookes radiant-matter tube was his source of influence, and he had generally used a photographic plate shut up light-tight in the ordinary wooden back of a camera. Above this he had placed various objects, and above these again the Crookes tube. The tube, under the influence of electrical excitation, gave out a certain amount of light, but this was accompanied by the newly-discovered radiations. Whatever these radiations may be, they affected the hidden plate in the same way as light, but in a far lesser degree, for the necessary exposure was from four to twenty minutes. He had not been able to learn what were the apparatus employed by Prof. Röntgen, but he himself found that no effects were evident when an ordinary induction coil was employed. He happened to have in use a lot of apparatus for high-frequency phenomena, and with this his experiments had been brought to a successful issue. He used an alternating current from the street mains which excited an induction coil; this coil charged a battery of 12 Leyden jars, the discharge of which was taken to a high-frequency coil in oil. It was the secondary coil from this latter to which his Crookes tube was joined. So far as results are concerned, Mr. Swinton found that many substances transparent to ordinary light, such as glass, are opaque to the radiations, and other opaque substances allow them to pass through freely. Ebonite, for instance, is exceedingly transparent to them; carbon, such as is used in the arc light, is the same. The metals seem to be opaque, with the exception of aluminium, but thin copper foil will also let the radiations pass. Mr. Swinton has some experiments in progress with metal plates of different thickness by which he hopes to find whether there is any analogy between their relative conducting powers for heat and electricity and their transparency for these radiations, and the results will be awaited with interest. Previous to the exhibition at the Camera Club, the writer of this note had an opportunity of seeing bromide prints of some of Mr. Swinton's plates. All the results described in the German experiments were reproduced, but in the case of the photograph of the living hand, the hand itself appeared partially transparent and showing the opaque bones embedded in it. The details of the articulations were distinct down the fingers, but were lost in the greater thickness of the back of the hand. The skeleton hand only can be obtained by varying the conditions. It is hardly likely that a sensitised plate prepared for quite a different purpose should be the best possible one also for the new radiations; and if photographs of this character could be obtained in a shorter time, they would obviously be of great use to the surgeon in cases of fracture with swelling, or in localising the position of foreign bodies. But the uses of the new discovery may be postponed for the present, although the possibility of examining the interior of normally opaque non-metallic substances is one that may easily prove of value to the electrical engineer.

Argon.—Lord Rayleigh delivered an address at the Royal Institution, Albemarle-street, last week, on the subject of "Argon." He said the first matter upon which he wished to speak was a dull but important one; it was the density of argon. At the meeting last year he had only been able to speak as to the density of argon prepared by the magnesium method. It was at that time his aim to weigh argon prepared by the oxygen method, and it was important to do so in view of the question whether argon prepared by the magnesium method was the same gas as that obtained by the oxygen process. He mentioned the difficulties he had to meet in getting three litres of argon, the amount with which he had been accustomed to work in his determinations of the densities of other gases. These difficulties were mainly due to the slow rate at which the nitrogen could be eliminated by means of the electric spark. He described the improvement he had effected in his apparatus at the suggestion of Prof. Ramsay. The nitrous fumes formed in the process were absorbed by alkali, and Prof. Ramsay's suggestion was to produce a fountain of alkali in the vessel, and so expose a larger surface for absorption of the gases. Another advantage gained was that the alkali solution welling up protected the glass from the heat of the flame. The voltage employed was about 3,000. In this arrangement nitrogen and oxygen were combined at the rate of about seven litres an hour. One curious effect was noted. Though the fountain made it quite possible to use a large arc in a small vessel, yet it was found that, everything else being equal, in these circumstances the rate of absorption was very much reduced. The determination ultimately made by Lord Rayleigh of the density of argon prepared in this apparatus was 19·940, which almost exactly equalled that found by Prof. Ramsay for the gas obtained by the magnesium process. This fact allowed the inference that the gases prepared by the two processes were identical, and also suggested, though it did not prove, that the gas was not a mixture. It was also unfavourable to the view supported by some eminent chemists that argon was an allotropic form of nitrogen, since the weight of that modification should be 21. Proceeding with his lecture, Lord Rayleigh said the next question was the refractivity of argon. He described the apparatus by which this property was examined, and the experiments he made. The result was to show that, while the refractivity of air was as 1, that of argon was somewhat less—namely, ·961. Helium obtained from a sample prepared by Prof. Ramsay was found to have a refractivity of ·146. What could be deduced from the fact? The refractivity of argon was nearly the same as that of air. He thought they could infer that it was not allotropic nitrogen, because if it were the refractivity could hardly be greater than the refractivity of air, which consisted mainly of nitrogen. The question whether any further inference could be made he must leave to chemists. Passing to his examination of the gas given off by the Bath springs, he said the proportion of argon appeared to be less than existed in the air. Subsequently, however, Prof. Ramsay discovered helium, and then it occurred to him as an explanation of this that helium, being as inert as argon, might be present in the residue, and by its lightness compensate for the heaviness of the argon. The gas from other mineral springs had been examined. Prof. Ramsay had examined that of one of the hot springs of Iceland; he found no unusual proportion of argon, and no helium at all. He (Lord Rayleigh) had examined the gas collected from the so-called nitrogen springs of Buxton. The proportion of argon in it was 2 per cent., and the indication of helium was doubtful. A good deal of interest lay in the question whether there was helium in the atmosphere. If there was any considerable portion it would be accumulated with argon, and one would expect to see the characteristic helium line in the spectrum of argon. He did not think that anyone had ever seen it. That might be taken as proof that there was not 2 per cent. of helium in argon, and as argon was only 1 per cent. of the atmosphere, there could be only about two parts of helium in 10,000 of atmosphere. Lord Rayleigh concluded his discourse with some experiments to show that the viscosity of argon is decidedly greater than that of air (1·21 : 1), while that of helium is somewhat less than air.

COLOGNE CENTRAL STATION.

During the autumn of last year we paid a visit to the Cologne central station, under the guidance of Mr. C. P. Feldmann, and also to the municipal waterworks adjoining the central station, where we met also Mr. E. Froitzheim. These gentlemen have specially written a paper dealing with the combined municipal works of Cologne relating to water and electricity. That part dealing with the waterworks formed the subject of a paper read before the English Waterworks Engineers at Nottingham on January 11 last, and will be found in the *Contract Journal* of January 15 and 22 last; the part relating to the central station is given herewith.—ED. *E. E.*

Cologne Electricity Works,

Being the second portion of a Paper on the Municipal Works of Cologne, by CLARENCE P. FELDMANN, Electrical Engineer to the Helios Company, of Cologne-Ehrenfeld, and ENGELBERT FROITZHEIM, Chief Engineer of the Municipal Waterworks of Cologne.

HISTORICAL REMARKS.

The Cologne electric central station has been excellently described in the very comprehensive work of Mr. Coerper,* to those points which have not yet been published in English journals, or which show details of special interest.

Electric lighting was publicly used in Cologne in 1880 during the festivities in celebration of the completion of that magnificent cathedral the foundations of which were laid six centuries before. A few years after the Paris Exhibition there were several private electric plants, some of which continued working for nearly 10 years. They were then connected to the mains of the central station. One of these plants consisted of an Otto gas-engine driving a dynamo and placed in the middle of a beer-saloon without any partition walls or protective railings, thus giving light, sound, and smell at the same time. At the close of 1889 the first of the three existing plants was erected; the total number of lamps fed by these plants is 2,150 incandescent and 190 arc lamps. In the meantime the authorities had been actively preparing plans and studying the question of a municipal electric station. Towards the end of 1887, Mr. August Hegener, then manager of the gas and water works, had adjudicated upon the tenders of Messrs. Siemens and Halske, of Berlin; S. Schuckert, of Nuremberg; and the Helios Company,

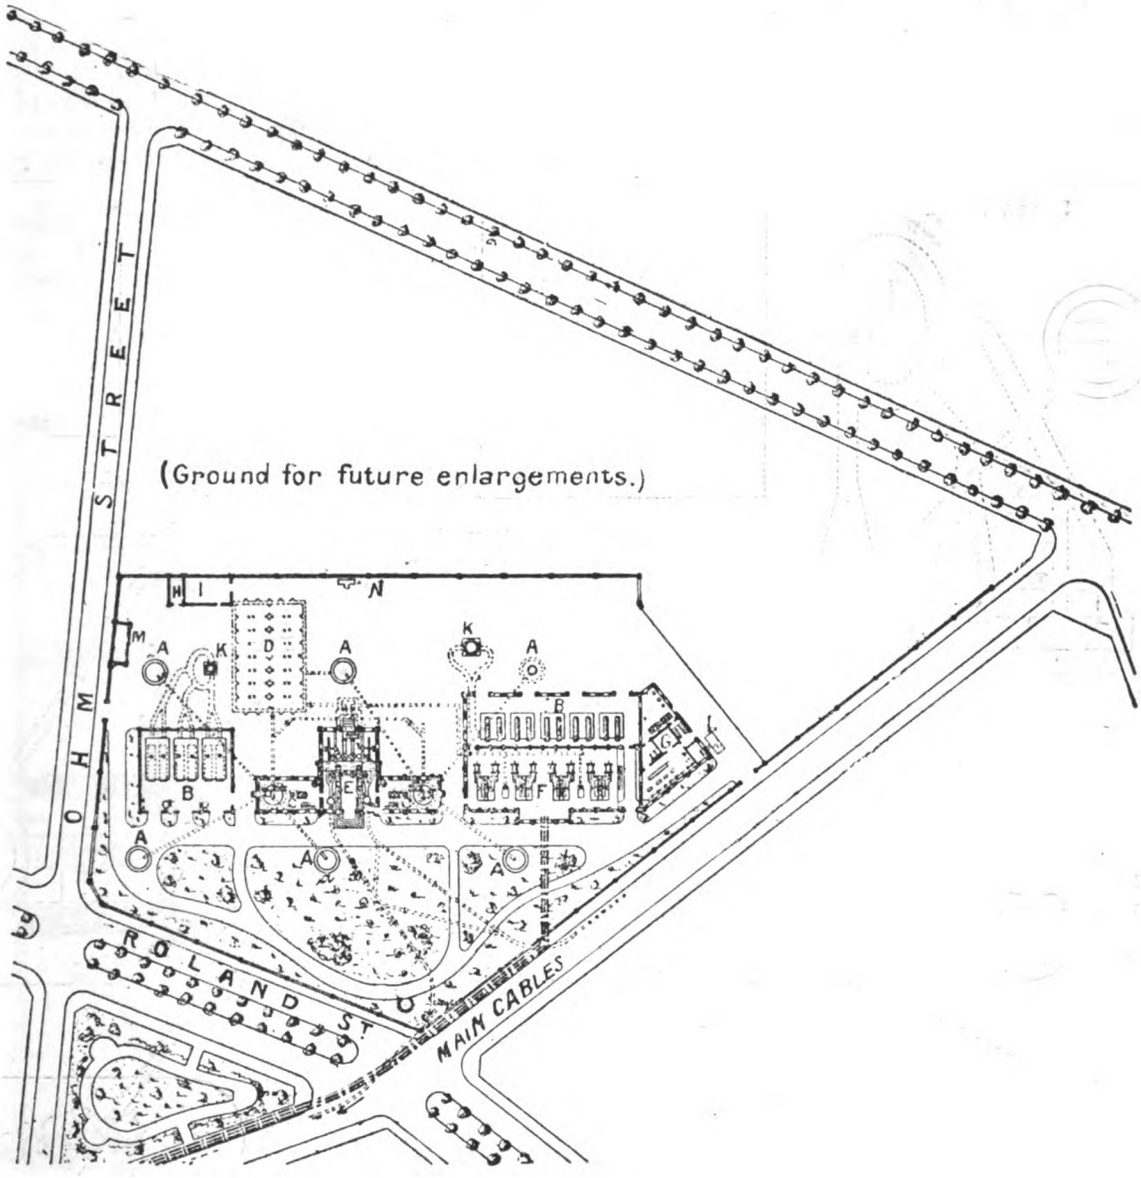

FIG. 1.—Site of Cologne Waterworks and Electric Light Station.

the managing director of the Helios Company, of Ehrenfeld, near Cologne. We shall, therefore, limit our description Limited, of Cologne-Ehrenfeld, and had stated that: "The erection of a central station, and the provision of several thousands of horse-power in engines and boilers in the centre of a closely-built town, is not at all desirable. The erection of several smaller stations with gas-motors is also not recommended on account of the high cost of the sites, the

* "The Electric Central Stations at Cologne and Amsterdam," by Carl Coerper, managing director of the Helios Electric Company, Cologne-Ehrenfeld. Translated from the German by Clarence P. Feldmann, electrical engineer.

Digitized by Google

complicated and expensive working, and the difficulty of supervision. Therefore, a station erected near the outskirts of the town upon spare ground at the site of the waterworks would be most conveniently situated. A station so situated would be economically worked by using the alternating-current system with transformers. Again, the danger connected with this system on account of the high pressure can be reduced to a minimum by a careful installation, the inferiority of the alternating arc lamp being only a small matter as compared with the other advantages. "Therefore," his report concluded, "the alternating-current system with transformers is to be preferred for Cologne, and its employment is recommended." In accordance with this report the authorities of the city accepted the tender of the Helios Company, and granted the necessary means on February 13, 1890. The building was commenced in April, 1890; 17 months later the 600-h.p. engines and dynamos were working upon the network; buildings,

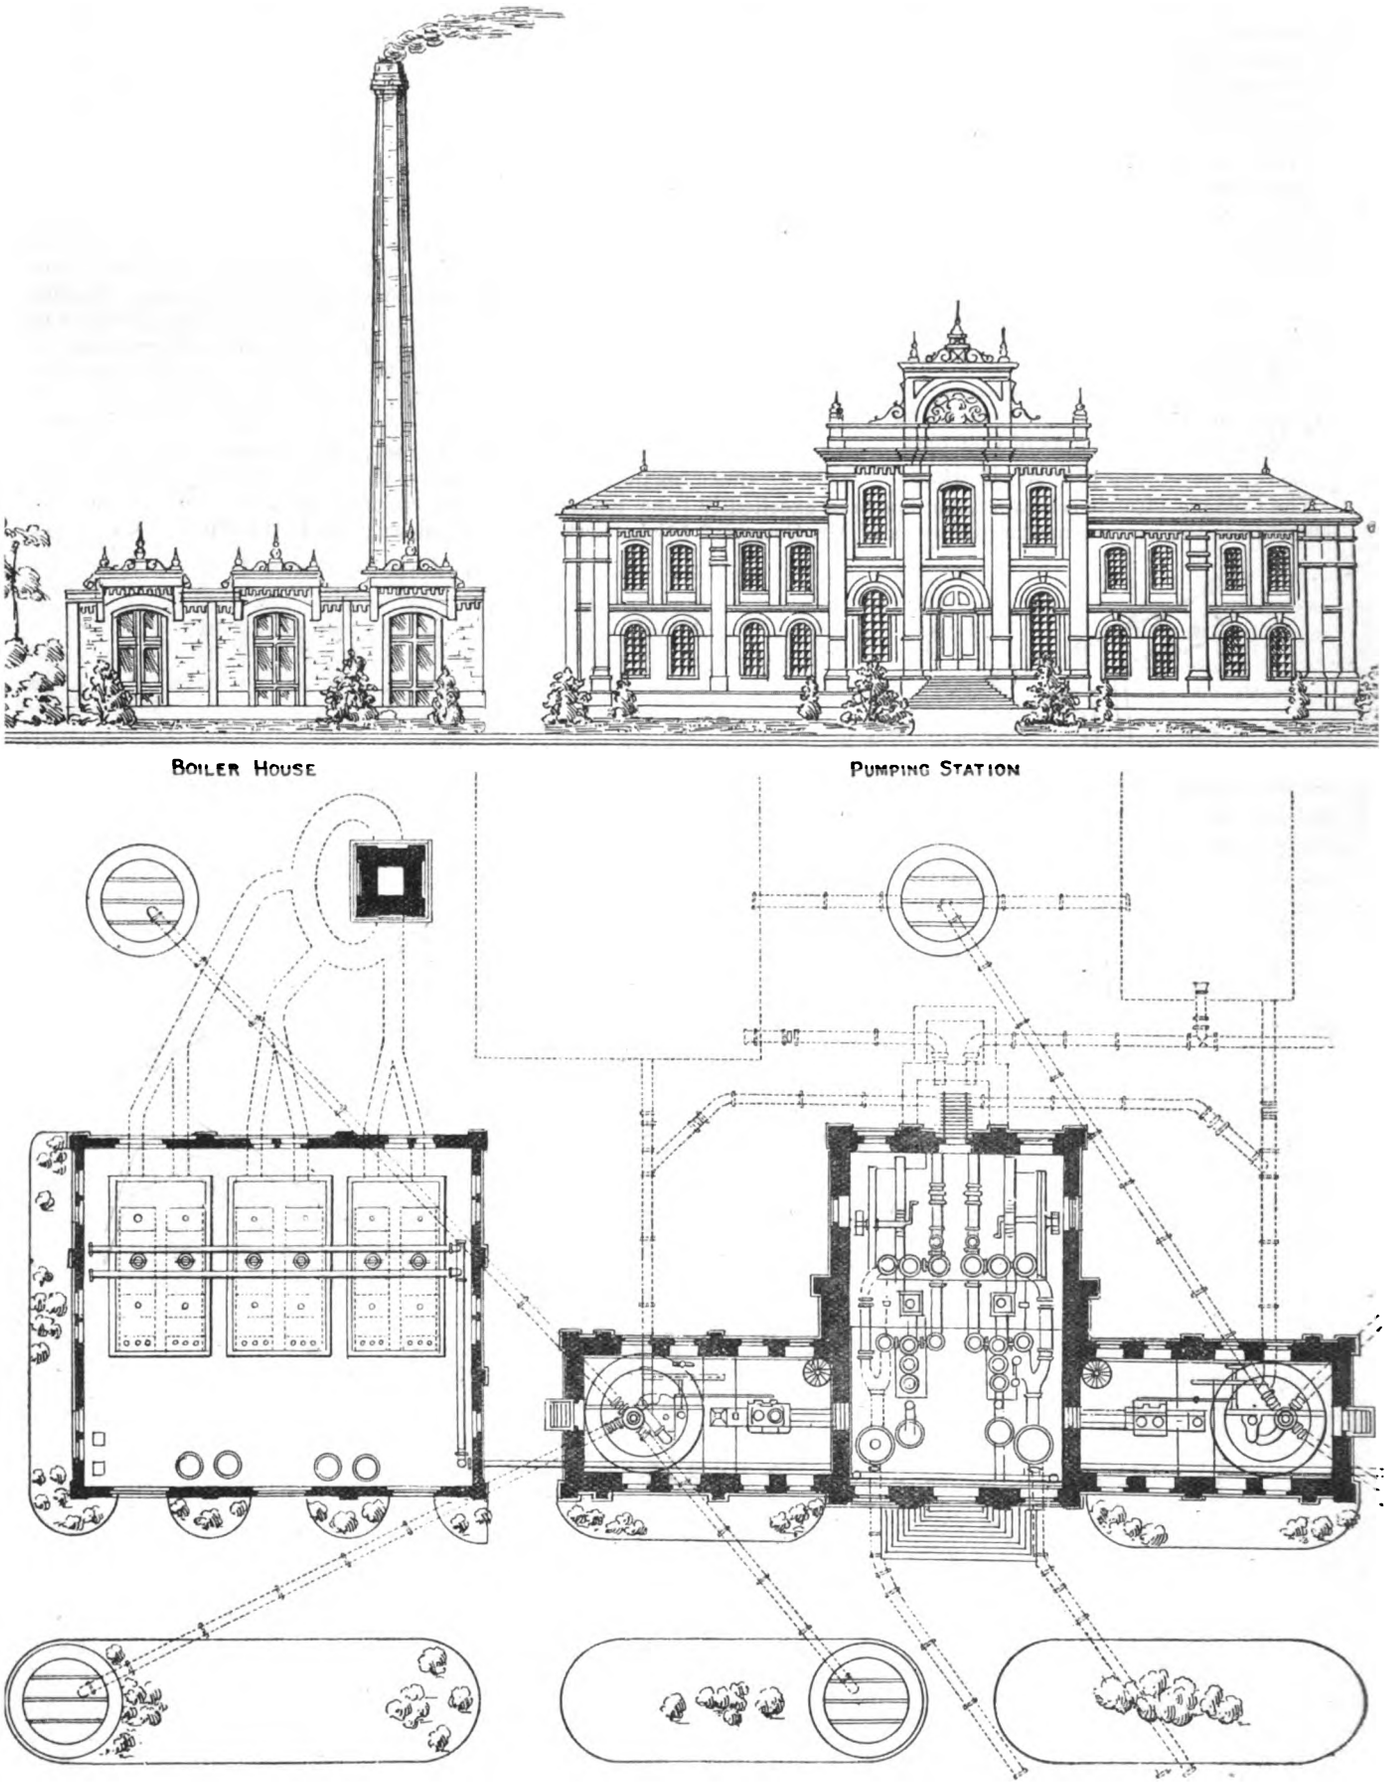

FIG. 2.—Plan and Front Elevation of the Cologne Waterworks.

Digitized by Google

travelling cranes, engines, and dynamos were supplied by different manufacturers, their erection being carried out under the supervision of the gas and water works engineer.

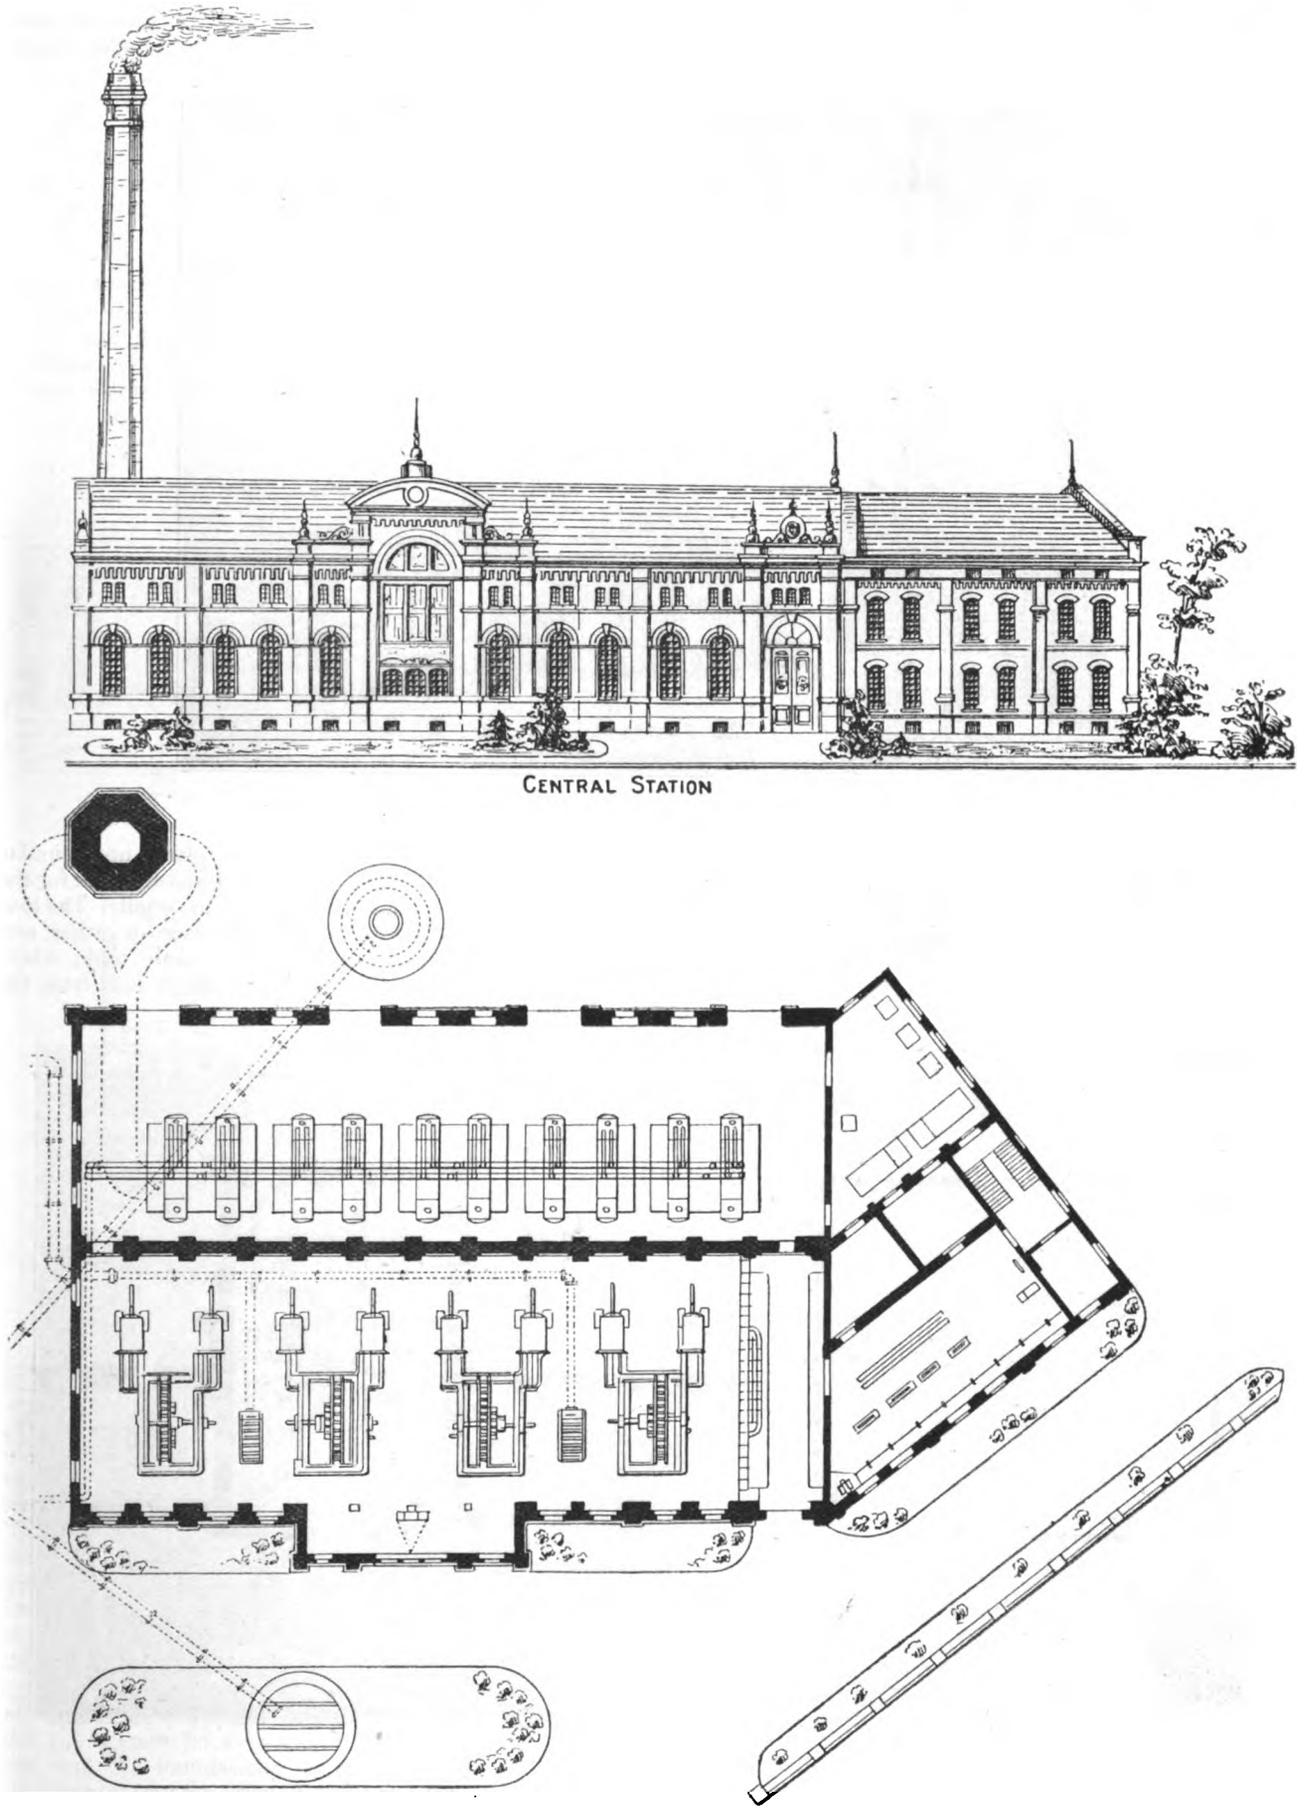

FIG. 2A.—Plan and Front Elevation of the Cologne Electricity Works.

Up to the present time there has been no failure, and the guarantees have all been reached or surpassed.

BUILDINGS.

The situation of the buildings is seen from the plan (Fig. 1) and shown on a larger scale in Fig. 2. The works consist of the engine-room, F; the boiler-room, B; and the triangular rooms, G, which contain a workshop, two laboratories, a waiting-room near the weighbridge, and a room for the feed pumps and water-purifiers. The simple but tasteful form of the front elevations is shown in Fig. 2. The length of engine and boiler room is 150ft., breadth 52ft. 6in. and 42ft. 6in. and height 52ft. 6in. and 36ft.

Digitized by Google

respectively. Under the engine-room there are two cellars, each about 11ft. 6in. in height. The upper cellar contains the air-pumps and the exhaust-pipes from the engines, the artificial load resistances, and the connecting wires from the dynamos, and a special opening is provided in the foundation under every dynamo for the valves and condenser connections of the engines. Thus every important part is easily accessible, and may be inspected at any time. The lower cellar contains the condensing-water service pipes and tanks, and is nearly on a level with a water-reservoir between the pumps of the waterworks. The vaults below the boiler-house contain the usual arrangement of flues and ashpit, and in front of them are two long tanks for the softened water, with an overflow towards the reservoir below the softeners, from which the feed-pumps force the water into the boilers. Fig. 3 shows the interior of the engine-room.

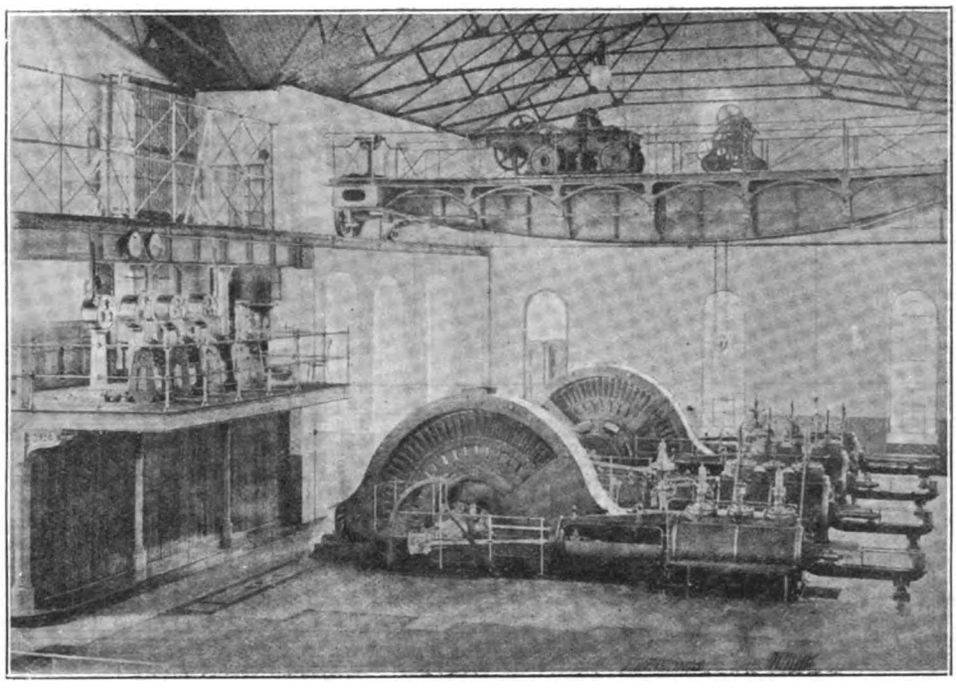

FIG. 3.—Interior of Engine-room at Cologne.

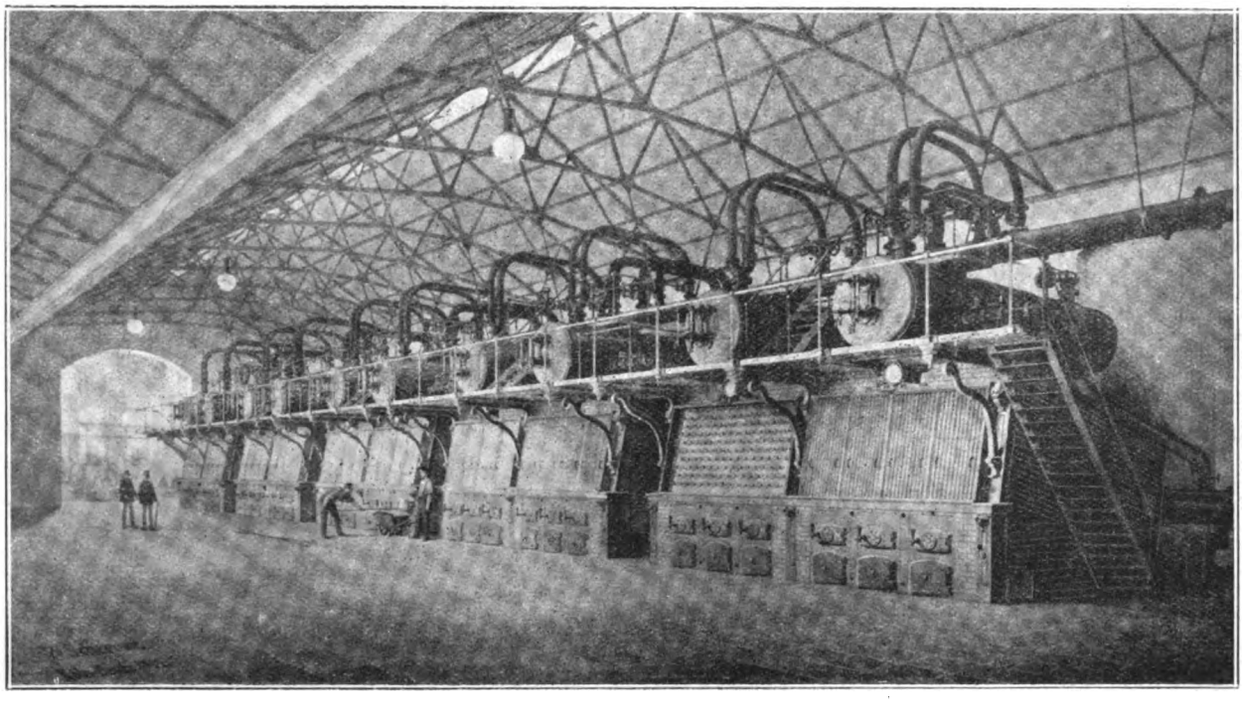

FIG. 4.—View of the Boiler-house.

ENGINES.

The engines are of the well-known Sulzer type. They are horizontal compound engines, with cylinders of 27¾in. and 37½in. diameter and 4ft. 1½in. stroke. At 85 revolutions per minute and a pressure of about 85lb., and 22 to 38 per cent. cut-off, they yield 500 to 650 effective horse-power. There are at present three engines, the fourth being a smaller one-cylinder engine giving 150 effective horse-power. It is placed upon similar foundations as the three large ones, and was designed for the day load, for which, however, it is now too small. The low-pressure sides of adjacent engines are placed together, and take their condensing water from the same tank, which is placed below the two staircases which lead from the engine-room to the first cellar. The air-pumps are worked by means of a swinging arm from the main crank. The dynamo and exciter are placed upon the main shaft without special flywheels. Only the small engine has a separate flywheel of relatively small size. The regulation of the engines is so good and the number of revolutions varies so little that synchronous clocks may be worked from the

Digitized by Google

dynamos, this being the most delicate tachometer that could be imagined. To this point we shall return later on.

Boilers and Accessories.

The boiler-house is designed for 10 tubular boilers, of which eight of Steinmueller's system are erected. Each boiler has 2,350 square feet of heating surface, and contains 140 water-tubes, 14ft. 3in. long, of 3¾in. exterior diameter, and ·140in. thick. At both ends of each boiler these 140 tubes are firmly connected to a wrought-iron water-chamber, the connection being secured by expanding rollers. Through vertical tubes these water-chambers communicate with the upper boiler, whose length is 21ft. and diameter 4ft. 3in., and which lies completely outside of the flues. The grate surface is 54 square feet. The fire-bars are of wrought iron, their width being ·315in., spaced ·150in. apart. The grate thus formed is a very durable one, and excellently adapted for the smokeless consumption of the mixture of poor Westphalian boiler coal and the dross left after sifting the broken coke from the gasworks. The heating effect of these small particles of coke is about half of that of the coal used—1lb. of coal evaporating 8lb. of water. All feeding devices and steam and water connections are duplicated (see Fig. 4). The two steam-pipes are spirally-welded wrought-iron tubes, 12in. in diameter and ·30in. thick; they are connected by means of welded rings and loose flanges. Each of these steam-pipes may be connected to the boiler plant in the waterworks, so that the two boiler plants may mutually supplement each other. The space between the exterior wall of the boiler-house and the foundations of the boilers is arched over, and forms a reservoir for the purified feed water. It is able to hold 1,770 cubic feet of water, and thus allows of a continuous and regular working of the water-purifying devices, although the consumption of purified water varies largely with the load. Below the boilers, and near the wall separating the boiler and engine rooms, are the ashpit and the flues. The chimney stack is of circular shape, and is 8ft. 5in. diameter inside throughout, and 196ft. high. It is erected upon a concrete foundation 31ft. square, at a depth of 17ft. 6in. below the ground.

The two purifiers are each able to furnish 175 cubic feet of softened water per hour. They work continuously, and take about 13 or 14 parts of lime out of the normal amount of 16 in 100,000, leaving only between two and three parts in the feed water. The boilers have worked continuously for periods of three months. Since the opening, four years ago, there has not been the lightest trace of incrustation in the water-pipes, which are only cleansed from the small muddy deposit by means of brushes. The purifiers may be fed either from the condensing-water tank below the entrance in the engine-hall or from the waterworks supply. The softened water leaving them flows to the feed-water tanks in the boiler-room, from which it is lifted by means of compound steam-pumps, working with condensation and able to furnish 80 cubic feet per hour at 60 revolutions per minute. One pump is still sufficient for the four boilers generally in use, but three pumps have been put down.

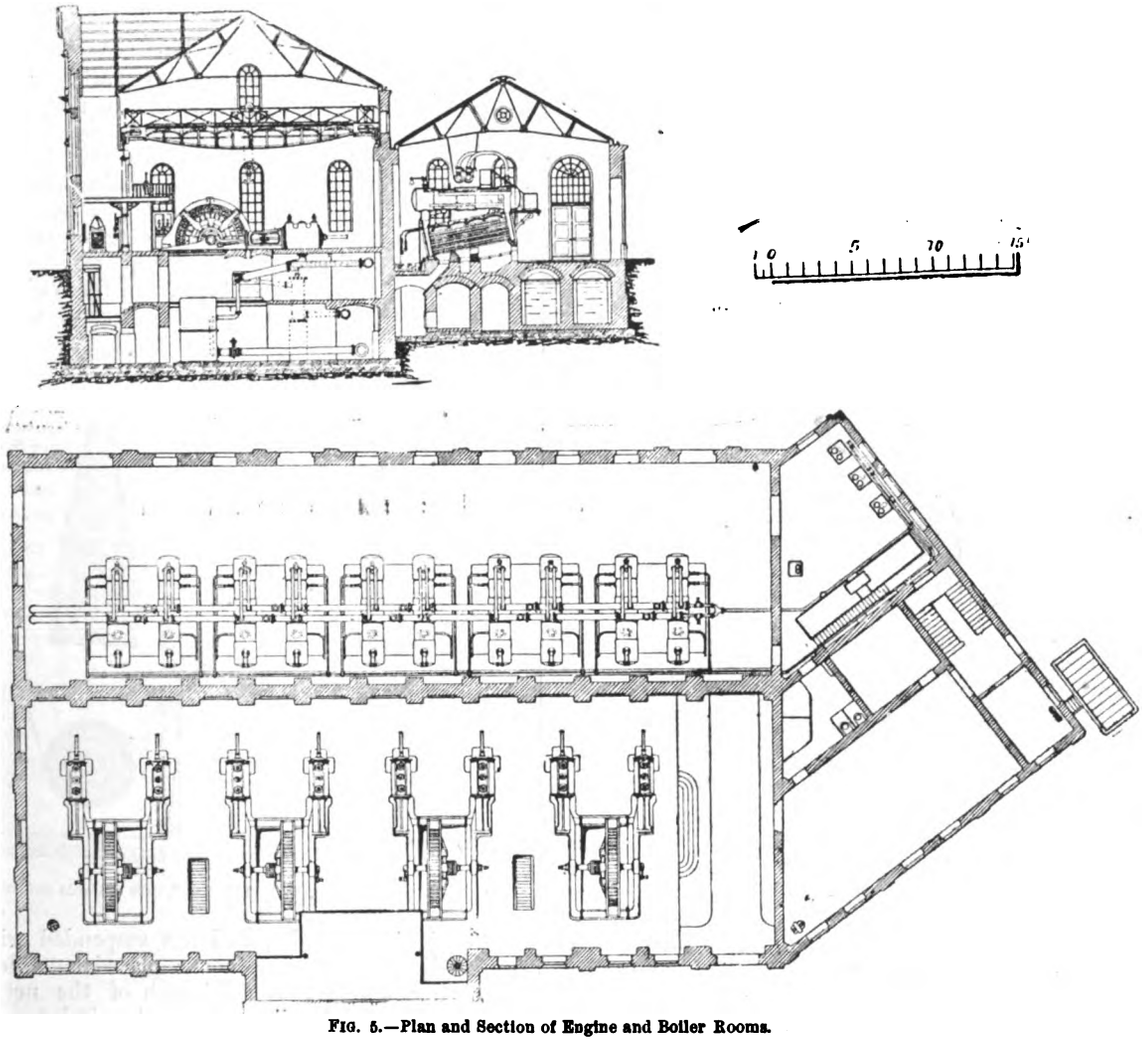

Fig. 5.—Plan and Section of Engine and Boiler Rooms.

The guarantee for the boilers was a production of 7,500lb. of steam per hour, or 8lb. per pound of coal burnt. The test, however, showed the possibility of producing with one engine and one boiler 809 i.h.p., corresponding to 11,400lb. of steam, or about 10lb. of steam per pound of coal burnt. The total amount of water in the steam-pipes and the water-separators was 162lb., with a total consumption of 29,200lb., or about 0·6 per cent. This is at once a proof of the dryness of the steam, as the total amount of water lost, of which at least a part is due to condensation, is smaller than the guarantee of 1 per cent. for water carried over with the steam. The accompanying figure shows a view of the boiler-house, with the purifiers and pumps.

Dynamos.

There are three dynamos, giving an output of 300 kilowatts normal and 360 kilowatts maximum; but they have been designed so that they may be worked at 440 kilowatts during several hours without heating more than about 25deg. centigrade above the surrounding air. Their con-

Digitized by Google

struction is very much like that of the Zipernowski machines. The diameter of the "star" wheel forming the 72-pole field is about 14ft. 2in.; its peripheral velocity is 3,570ft. per minute at 85 revolutions. Alternators and exciters are both built up of sheet-iron stampings 19·7 mils thick, according to an English patent, No. 9,013/1887, granted to Mr. Carl Coerper. The exciters are compound wound, so as to secure a certain degree of safety. A compound-wound dynamo will always excite itself and its alternator, even if by some mistake its terminals be directly connected to the low resistance offered by the alternator field coils at the moment of starting. When coupling parallel, both alternators and exciters are connected, but each of the ring armatures of the eight-pole exciters is able to excite two alternators. The maximum output of each exciter is 130 volts and 300 amperes at 85 revolutions. In August, 1893, these dynamos and engines were tested before being finally accepted. They were loaded during 10 hours with 505·2 i.h.p., and took 14·8lb. of steam per indicated horse-power hour; the guarantee had been 15·4lb. At an output of 324 kilowatts, as measured by means of a Ganz wattmeter, the dynamo gave 544·4 watts

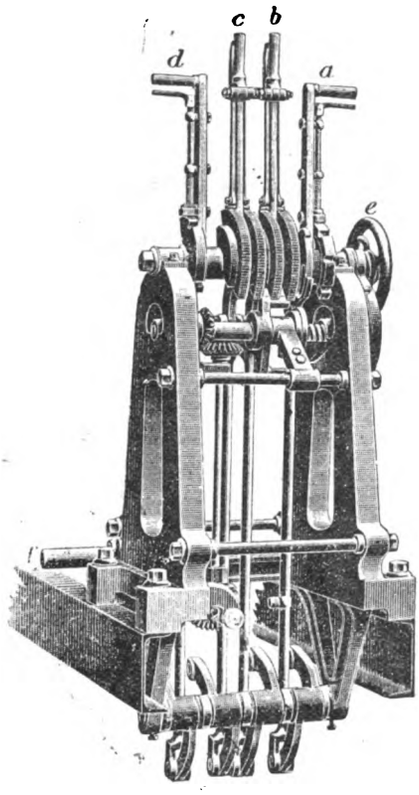

FIG. 6.—Switch Levers.

per indicated horse-power, or 640·5 watts per effective horse-power; at an output of 421 kilowatts, the respective numbers were 520·4 and 612·2 watts per indicated horse-power and effective horse-power. During these tests the E.M.F. was kept constant at 2,020 volts. The numbers mentioned include all mechanical and electrical losses in alternator and exciter. The guarantee had been 513 watts per indicated horse-power—*i.e.*, 69 per cent. efficiency.

Fig. 5 shows the dynamos and the engines in plan and section. Fig. 3 represents also the position of the travelling crane, which spans the whole width of the engine-room and is able to lift the heaviest parts. The switching platform can also be seen. The crane travels the whole length of the engine-room; it was erected before the engines, and is actuated by hand. At the end of the engine-room, before the staircase, shown in front of Fig. 5, there is an entrance wide enough to admit the largest parts of engines and dynamo. These can then be lifted by the crane and placed in their different places. In this way the engines and dynamos were erected.

Switching and Regulating Devices.

These are of special and most original design. They have been patented by Mr. Carl Coerper, and resemble somewhat the apparatus used for blocking and connecting railway tracks. Lever A (Fig. 6) controls the alternator lever; D the exciter; the levers B and C move the hands of a rheostat for fields of alternator and exciter respectively. E is a handwheel, by means of which an artificial load resistance is introduced in the main circuit of an alternator which is to be coupled in parallel or loaded for testing purposes. F is a crank connected to a set of horizontal and other levers which move the proper rheostats and switches arranged in a chamber below the platform, the double-pole switches having mercury-cups with partitions. The process of parallel coupling has been described at various places. It may suffice to state that every dynamo works 24 hours—from noon to noon—is then coupled parallel to another one loaded by means of the load resistance, and then exchanged by throwing the resistance upon the former, the load upon the new dynamo. During winter two dynamos run parallel during several hours of the day, all three having been used simultaneously and in parallel so far only for trial. The first basement contains the three mercury switches (Fig. 7), actuated by hand, used for the three main cables.

Network.

There is only a primary high-tension network, the transformers being placed invariably in the houses of the customers. This primary network is represented by the accompanying table, whose numbers give the section of each of the concentric conductors forming the cables used. The insulation between the interior conductor and the lead cover below the concentric exterior conductor, and between this conductor and the double exterior lead cover, varies between 6mm. and 7mm. for the various sections employed. The cables are placed in wooden troughs, which

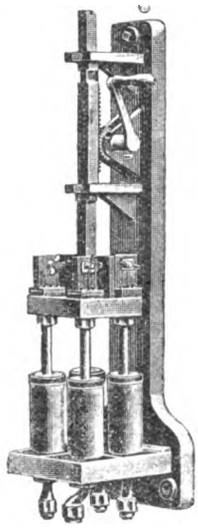

FIG. 7.—Mercury Switch.

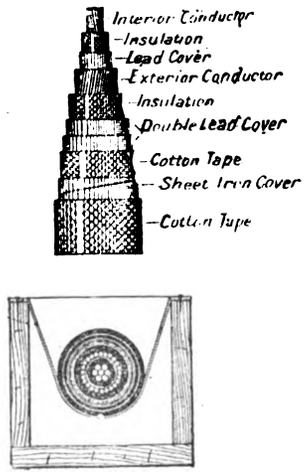

FIG. 8.—Details of Cable and Wood Trough.

are filled with asphalte, and are suspended within these troughs by means of iron hooks placed suitable distances apart (Fig. 8). The total length of the network is at present about 17½ miles. Its design is interesting in so far as it was one of the first networks to be thoroughly designed theoretically with regard to loss of pressure and distribution of currents *before* it was laid down or even ordered. Three feeder cables go from the station, each of ·340 square inch section, in each conductor. At the time of the first installation there were only two going to the point A (see Fig. 9). From this point, to which the loss would be found directly from Ohm's law, there spreads a complicated network with 10 closed meshes (marked by Roman ciphers). The distribution of the current for this network may be found exactly and with but a relatively small amount of labour, by means of the method of sectioning published by Messrs. Herzog and Stark, of Budapest, in 1892, and described, enlarged, and modified by Mr. Herzog and one of us in a special treatise upon the calculation of networks. This method is nothing but a physical interpretation of Kirchhoff's laws, and consists in placing one section per closed mesh at any point from which a customer is tapped; the consumption at this point may be zero, as at the points A, B, C, D (Fig. 9). For this point the sum of the arriving

Digitized by Google

currents is (A + B + C + D), the sum of the leaving currents, or those arriving from the opposite side being (A + B + C + D). For the point G the customer on one side of the section is supposed to take G, the one on the other side taking (8·6 – G) amperes. Proceeding in this way, the whole network was changed into a set of open—*i.e.*, simple—branch lines, which are all in connection with the feeding point, A. For these open lines the total current distribution is easily found from Kirchhoff's laws: and the values found for the unknowns, whose number is 10, equal to the number of closed meshes, gives directly the intensity and direction of the unknown currents ending at or passing across the chosen sectioning points and the real position of these sectioning points for the given distribution of customers. In the present case the values of the unknowns were:

A =	91·0 amperes	.....	G = 41·2 amperes
B = –	92·5 amperes	.....	H = 5·3 amperes
C =	107·0 amperes	.....	L = 18·3 amperes
D = –	83·2 amperes	.....	M = 21·5 amperes
F =	11·1 amperes	.....	P = 80·2 amperes

The customers and their consumption are indicated by arrows standing vertical upon the conductor, the accompanying numbers showing the intensity in amperes; the numbers with circles give the lengths in metres divided by the corresponding sectional area in square millimetres, and the arrows parallel to the conductors, with their numbers, indicate direction and intensity of the currents in the respective parts of the network. Further details may be taken from the treatise mentioned; here it may suffice to say that the authors have modified the method, and have shown how to find from a sort of network ledger at once direction and intensity of current in any special conductor of the given network and for any distribution of the load. The accompanying figures refer to the maximum load of 602 amperes, corresponding to 24,000 lamps of 50 watts each; the corresponding losses are:

From A to *a*, 23·7 volts.
„ A „ *b*, 20·3 „
„ A „ *c*, 19·2 „
„ A „ *d*, 19·0 „

The method involves a large amount of mere calculating work, but this is fully repaid by the saving in the first cost, and by the splendid knowledge obtained with regard to maximum load of any special conductor, maximum loss, most favourable distribution of load, etc. England has been the place where the methods for calculating dynamos have been found out and improved. These admirable methods are rightly estimated very highly, but no English electrician would boast of not knowing or not employing them, though such boasting has been done in connection with the simple methods mentioned for calculating or studying networks.

(To be continued.)

CITY AND GUILDS OF LONDON INSTITUTE.

LECTURE XXII.

(Specially Contributed.)

Practical Voltmeters.—These are of two kinds:

1. Closed-coil instruments.
2. Open-coil instruments, which we may call static instruments.

The closed-coil instruments are of the galvanometer or ammeter type, so that the description of a few typical instruments will answer our present purpose.

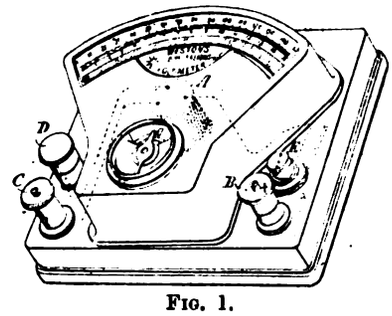

FIG. 1.

Weston Voltmeter.—This instrument is built upon the same principle as the ammeter previously described, except that it has a high-resistance coil of fine wire, A,

Digitized by Google

(Fig. 1) placed in *series* with the moving coil *instead* of a low-resistance coil in *parallel* with it. The high-resistance coil is wound in two sections of different lengths and resistances. One section only can be used by making the connections with the binding screws, B D, or both sections can be used in series by making the connections with B C. This gives the instrument a wider range of usefulness. E is a key for contact-making.

Range of Instruments.—It has been pointed out that the instrument used must not invalidate the test; hence with regard, say, to ammeters, the resistance of the instrument must never be large compared with the resistance of the circuit. With regard to high-resistance coils, these must not be used with too large a current for fear of fusing; hence each class of instrument is only adapted for a certain range, outside of which there is danger to the instrument, or the test is fallacious. As a rule, all these closed-coil voltmeters are used but temporarily—that is, a key is pressed, or a switch is turned, and a reading taken—otherwise the heating effect would spoil the instrument. Ammeters are most often kept permanently in the circuit, because the instrument suffers no harm from the current. For the reasons stated, the same instrument will not do for all purposes, but each instrument must be adapted for the particular use to which it is to be put.

Hummel Voltmeter.—This instrument is constructed upon the same principle as the ammeter previously described. A slight modification has been made by Bain, in America, who replaces the soft-iron tube by a thin soft-iron vane.

Bardon's Voltmeter is, like some ammeters described, based upon the action of a solenoid upon a soft-iron core.

Open-Coil Voltmeters.—The three quantities to be electrically measured, as we have seen, are pressure, current, and resistance. We know from every-day observation that pressure may be exerted against a resistance without any motion occurring. A boy may push against a rock, but his feeble push does not move the rock. Electrically, we may have pressure exerting or exerted against a resistance so large that the pressure exerted is unable to produce a current flow, or at least any current flow measurable by our instruments. If, in Fig. 2, S represents any source of electricity, and A B two plates of conducting material connected to the source, S, as shown, the plates, A and B, may be looked upon as the terminals of the source, and the difference of potential, or the difference of pressure, or the E.M.F., whatever you like to call it, between A and B is the same as between the terminals of the source. The air space between A and B completes the electric circuit, and the resistance of the air space is too great to allow of current flow. Instead of current flow, however, we get something that can be measured, which we call *charge*.

FIG. 2.

Any electric circuit of the kind just described, where the ends of the conductors, or the ends of the conductors enlarged, are connected only through air, or some other non-conducting material in the place of air, is called an *inductive* circuit. In an inductive circuit, the phenomenon called *charge* takes the place of the phenomenon called current in the conductive circuit, and is subject to the same law, or say law similar to that of Ohm. For convenience of formulæ, let us use the term "accumulation" instead of charge, and signify accumulation by the symbol A.

In the conductive circuit

Current × Resistance = Electrical Pressure;

i.e., $C \times R = E$.

In the inductive circuit

Accumulation × Resistance = Electrical Pressure;

i.e., $A \times R = E$.

Instruments fashioned to measure A instead of C, and by this means to obtain the value of E, are called electrostatic instruments, or open-coil instruments. Before describing any of these instruments it should be mentioned that in the inductive circuit, as in the conductive, the point at higher potential or pressure is called positive, or indicated by the sign +, to the point at lower potential, which is termed negative, or indicated by the sign −. Of these instruments, Wiener says: "Since no current flows across the charged bodies, no useful energy is consumed by this electrostatic method of measuring electromotive forces, and since the static electric charge is independent of the temperature and of the influences of magnetic fields, the readings of an electrostatic voltmeter are most reliable. As the polarity of the charge changes simultaneously in both bodies in case of an alternating current, electrometers may be used for measuring alternating electric pressures, for which purpose they offer special advantages on account of the absence of coils of wire subject to induction currents."

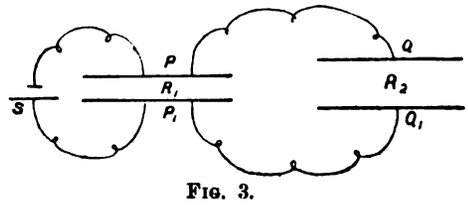

FIG. 3.

Let us consider some of the similarities of the inductive and conductive circuits. In the latter, if we decrease the resistance of the conductor we increase the current, with pressure remaining the same. So in the inductive circuit, if we decrease the resistance of the non-conductor, or dielectric, as it is called, we increase the accumulation, pressure remaining the same. The area of the surface of one of the opposing conductors may be looked upon as the area of the dielectric. By increasing the surface of the opposing conductors we increase the area of the dielectric and decrease its resistance, thus increasing the accumulation, with pressure remaining constant. Thus, in Fig. 3, if S is the source, P and P_1 the opposing conducting surfaces, by doubling the area of P and P_1, adding equal surfaces to each, as S and S_1 respectively, we halve the dielectric resistance and double the accumulation. The density of the accumulation on P P_1 is not altered—that is, the accumulation per unit of surface area; but under the new conditions the accumulation of S is the same as on P, the areas being the same and pressure constant, so that the total accumulation is that on P + that on S, or twice that on P. This addition of S to P in the inductive circuit is just the same as adding a second wire in parallel with the first in the conductive circuit, thus doubling the area of conductor and halving the resistance, with pressure constant doubling the current. We can have inductive

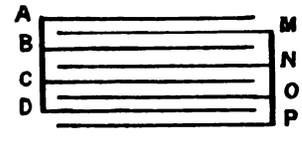

FIG. 4

resistances in series or in parallel, or a mixture of both, just as in the conductive circuit, and the same formulæ apply to the one as to the other, simply putting A in the place of C. It is convenient at times to have a considerable accumulation, just as it is convenient to have a large current, and then we modify our apparatus in order to get very large conducting surfaces opposite with very small dielectric resistances. Thus, if we take a large number of conducting surfaces, A, B, C, D, etc., and similar surfaces, M, N, O, P, etc., and oppose them as in Fig. 4, the ends of one set of surfaces, A, B, C, D, being in conductive contact as shown, similarly the ends of M, N, O, P with a dielectric such as air or paraffin between the surfaces, then the action of A, B, C, D is just as if it was one large

Digitized by Google

surface opposed to an equally large surface equal to M, N, O, P. The dielectric resistance is by such means very much decreased, and the accumulation increased. An apparatus of this kind is called a condenser. A condenser, then, is a piece of apparatus wherewith to obtain large conducting surfaces acted on in the inductive circuit, with small dielectric resistance and large accumulation, or greater capacity. The formula,

$$A = \frac{E}{R},$$

is as comprehensive for the inductive circuit as

$$C = \frac{E}{R}$$

is for the conductive.

INSTITUTION OF ELECTRICAL ENGINEERS, Jan. 23.

SIR DAVID SALOMONS in the chair.

At last night's meeting of the Institution the following candidates were balloted for :

Foreign Member.—A. E. R. Collette, The Hague.

Members.—Francis Wm. Clements, Gentz Gasse 50, Vienna ; Patrick Walter D'Alton, Croom's Hill, Greenwich Park, S.E. ; W. Fearnside Irvine, Johannesburg ; George Robert Mockridge, Western Union Telegraph Company, Penzance.

Associates.—George Frederick Adcock, Riverdale, Bourne End, near Maidenhead ; Howard H. S. Baker, Westminster Electric Supply Corporation, Limited ; Edward G. C. Barton, Brisbane, Queensland ; J. Augustus Bauer, 86, Leadenhall-street, London, E C. ; Selsey A. Cartwright, 60, Dale-street, Lancaster ; Percival Bailey Clarke, 29, Great Percy-street, W.C. ; Valentine Corin, Anchor Foundry, Penzance ; A. T. Durrant, 4 Queen-street, Great Yarmouth ; Edmund Lewin Birkbeck Hill, 1, Broad-street, Oxford ; Charles Morison Johnston, Town Hall, Lancaster ; Horace Algernon Marler, 139, Petherton-road, Canonbury, N. ; W. H. Miller, 61, Loch-promenade, Douglas, Isle of Man ; William Moat, Johnson Hall, Eccleshall, Staffordshire ; Lieut W. Montgomery, R.E., School of Military Engineering, Chatham ; Edgar Williams Newton, 18, Gladstone-street, Hartlepool ; George A. Pearson, 28, St. Andrews, Norwich ; Charles Edward Peebles, 15, Nevern-square, Earl's Court, S.W. ; John Milner Shackleton, Canon Brook, Lucan, co. Dublin ; Alfred H. Shepperd, Superintending Engineer's Office, Post Office, Belfast ; Frederick Martin Short, Durban Lodge, Woodchurch-road, West Hampstead, N.W. ; Wm. Rowan Wilson, 75, Waterloo-street, Glasgow.

Students.—Benjamin Herbert Isidore Adler, George Frederic Lewis Alexander, and John Drayson Dymond, Faraday House, Charing Cross-road, W.C. ; William Frederick Bolton Bronavon, Stoneygate, Leicester ; Harold William Holder, Somerstown, Holderness-road, Hull ; Frederick Watson Joll, 90, Claverton-street, Grosvenor-road, S W ; Hugh Sebastian King, 8, South-villas, Camden-square, N.W. ; Algernon Lionel Lennox, Messrs. Easton, Anderson, and Goolden, Erith Ironworks, Kent ; Laurence Moore Peel, Moore House, Beckenham, Kent ; H. F. Platt, The Laurels, Kingdon-road, West Hampstead ; Gabriel Arthur Maddox Rosetti, Salford Rolling Mills, Manchester ; Edgar Stopford Saunders, 51, Clarendon-road, Holland Park, W. ; Harold Skipwith, 24, Kempsford-gardens, Earl's Court, W. ; Frederic John Thompson, Melrose, Teddington, Middlesex ; Victor Watlington, 10, Fairfax-road, Bedford Park, W.

The **Chairman** said it was only a week ago that they were met in that room in a joyful spirit to move a resolution tendering their services to Her Majesty to assist her in case of need to defend her throne and our country. In one short week those feelings of pleasure had been converted into those of woe. A cloud had come over the palace ; a very estimable and venerable sovereign, a good mother, and a good woman had lost her son-in-law, and a beloved princess of ours had lost in this world her husband. They knew well that when there had been a sorrow in this country, or in any other country, afflicting any number of people, or even a single person, Her Majesty had always been the first to sympathise with them in their grief. At such moments as this we as Englishmen and as men, quite apart from our nationality, joined our hearts to those of the Royal Family, to the Queen and Princess in their distress, to express our deep sympathy and grief with them in their trouble. He asked the meeting to pass a special resolution expressive of the great regret with which the Institution had received the news of the untimely death of H R.H. Prince Henry of Battenberg, and that the members desired to be allowed to lay before Her Most Gracious Majesty their expression of profound sympathy with the Queen and the Princess Beatrice in the great bereavement which had overtaken them.

Major-General Webber added a few words, and asked them to remember that it was in furtherance of the great wish to identify himself with the volunteer service of this country, to which he already belonged, that led Prince Henry of Battenberg to volunteer for the Ashanti compaign, so that he might have the opportunity of seeing some active, practical service in the field. He was a man who in late years they had learnt to regard with very great feelings of kindness.

The resolution was passed in solemn silence.

The discussion on "Wiring" was then resumed.

Mr. Geipel said he endorsed the opinion of Mr. Bathurst that it was undoubtedly the expense of wiring buildings which led to objections to the electric light. Those who were interested in electricity were doing their utmost to reduce the cost of supply, and the lamp-makers were doing likewise ; yet, to judge from the tone of the remarks at the recent Board of Trade conference, an attempt was being made by some of them to increase this cost of wiring by raising the standard to an unnecessarily high pitch. Do not let them saddle their work of wiring with more unnecessary conditions than they could help, but by all means they must protest against shoddy work. He regretted to see a tendency among engineers of the low-tension system to force a 200-volt supply upon the consumer, and contractors would do well to join consumers and protest emphatically against this practice until such time as absolutely reliable and cheap 8-c.p. lamps were obtainable for that pressure. He was afraid there was a notable absence of figures in the two papers as to first cost. He hoped the members of that institution and the fire insurance companies would not be alarmed as to the somewhat pessimistic remarks and warnings of Mr. Mavor as to the necessity of greater stringency. With regard to the casing, unless concentric wiring was about 50 per cent. cheaper he was afraid it would not help them. As to the soldering of all contacts, that necessitated a soldering iron, and there was not that objection with the ready-made mechanical contact. He agreed as to the importance of what Mr. Mavor described as grouping the branch fuses at distributing centres, and considered the method should be made compulsory, especially as it involved no increase in the first cost.

Mr. Hancock said he was not altogether sure that insulating the pipe and reducing the insulation of the cable was exactly the right thing. In the first place, by putting the insulation inside the pipe they reduced its capacity a great deal ; and in the second place, if the life of vulcanised rubber was only three years, he would like to ask if they allowed 33 per cent. depreciation.

Mr. McLean (Oxford) would like the question to be looked upon from the point of view of the central station engineer. At Oxford he might have six or seven installations going on at once, and he had to look after them all. If he neglected to do that and an electrical fire occurred his company's credit suffered and his own credit suffered. There were a number of very pretty things for exhibition on the table, but he thought he could show just as nice things with the old wooden casing. Under floors they would find all sorts of things were done however perfect the system they adopted might be in theory. As for what had been said on the subject of 200-volt lamps, he would like to see them, but he thought that if they turned a 200-volt current into some installations he knew of, the light would not be at the lamps, but somewhere else altogether. He was glad to see the clause in the new regulations of the Board of Trade that if the consumer's insulation fell below a certain point, the current should be cut off. The action of the insurance companies in proposing to raise the premiums on central stations was most unreasonable.

Major-General Webber agreed with this, and suggested that the insurance companies did not appreciate how the fire risk was lessened by installing the electric light. There were many large warehouses at the seaports where it would be to the advantage of the companies if they would encourage the introduction of the electric light by reducing their at present very high rate. In considering the various systems of wiring, open work must not be forgotten. In his own house some done very long ago had proved most satisfactory.

Mr. Langdon thought wood casing was good enough in the open but tubes should be used in hidden work.

Mr. Donovan having spoken, **Mr. Antill** referred to the satisfactory character of the open work at the British Museum, while **Mr. Campbell Swinton** spoke of the difficulty of contractors using more than one system with one staff.

The discussion was then adjourned to the next meeting.

WHAT, WHEN, AND WHERE.

Institution of Junior Engineers.

January 25, 7 p.m.—At the Westminster Palace Hotel, S.W. Anniversary dinner.

Electro-Harmonic Society.

January 31, 8 p.m.—At St. James's Hall Restaurant, Regent-street, W. Smoking concert.

Society of Arts.

January 27, 8 p.m.—At John-street, Adelphi. Cantor lecture, by Dr. J. A. Fleming, F.R.S., on "The Construction of the Transformer." Lecture II.

January 29, 8 p.m.—Eighth ordinary meeting. "Standards of Light," by W. J. Dibdin, F.C.S.

Institution of Civil Engineers.

January 28, 8 p.m.—At Great George-street, Westminster, S.W. "Recent Developments in Gas-Engines," by Dugald Clerk, A.M.I.C.E. Discussion.

Physical Society.

January 24, 5 p.m.—At Burlington House. 1. Exhibition of geometrical instruments by E. Scott and Signor Monticolo. 2. "Resultant Tones," by Prof. J. D. Everett. 3. "Experiments with Incandescent Lamps," by Sir D. Salomons.

Liverpool Engineering Society.

January 29.—At Adelphi Hotel, Liverpool. Annual dinner.

TO CORRESPONDENTS.

All Rights Reserved. Secretaries and Managers of Companies are invited to furnish Notice of Meetings, Issue of New Shares, Installations, Contracts, and any information connected with Electrical Engineering which may be interesting to our readers. Inventors are informed that any account of their inventions submitted to us will receive our best consideration.

All communications intended for the Editor should be addressed C. H. W. Biggs, *139-140, Salisbury Court, Fleet Street, London, E.C. Anonymous communications will not be noticed.*

TO ADVERTISERS.

Advertisements should be addressed to the Publisher, 139-140, Salisbury Court, Fleet Street, E.C., and should reach him not later than noon of Thursday. **Special Terms** *for a series can be arranged on application.*

"SITUATIONS VACANT" and "WANT PLACES" Advertisements will be charged at THREE WORDS for ONE PENNY with a MINIMUM charge of SIXPENCE.

TO SUBSCRIBERS.

"The Electrical Engineer" *can be had by Order, from any Newsagent in Town or Country, and at the various Railway Stations; or it can, if preferred, be supplied direct from the Office on the following terms:*

	3 months.	6 months.	12 months.
United Kingdom	3s. 3d.	6s. 6d.	13s. 0d.
Other Places	4s. 11d.	9s. 9d.	19s. 6d.

(Post Free, Payable in Advance.)

Cheques, Post Office and Postal Orders for Subscription and Advertisements should be made payable to C. H. W. Biggs, *139-140, Salisbury Court, Fleet Street, London, and be crossed "Union Bank."*

BOUND VOLUMES.

Vol. XV. of new series of "The Electrical Engineer" can be had bound in blue cloth, gilt lettered, price 8s. 6d. Subscribers can have their own copies bound for 2s. 6d., or covers for binding can be obtained, price 2s.

DR. HOPKINSON ON METHODS OF TEACHING.

It is now many years since the tripos list was issued with the name of Hopkinson as Senior Wrangler, but the time is vividly recalled to our memory because a relative of the Senior Wrangler who was full of the idea that the promise shadowed forth by the position of the student would be amply fulfilled in practice in years to come rushed into our room with the welcome news, and, in fact, was as excited over the success as friends usually are. The promise has been fulfilled, for there is no more sounder theorist, no more prominent practician whose speeches and papers command greater attention than Dr. Hopkinson. A second time his colleagues have elected him to the presidential chair of the Institution, and his inaugural address is before us. It deals with a question which is all-important, and though others have laboured in the same direction their efforts could not expect to obtain the sanction and authority which necessarily clings around the words of so eminent a man as the President of the Institution. Many years ago, out of curiosity we examined a number of school-books issued at various periods from the beginning of the century and the time of examination, somewhere about the year 1876, and found that practically author had followed author, each treating his subject in the same manner; and ofttimes the paragraphs in the earlier books were to be found in almost identical words in the later books. The books examined were electrical books, but the reason for examination was to discredit the system by which every publisher of school-books seemed to want to issue a book on every conceivable subject. No doubt the publisher is right from his business point of view, but we then held, as we now hold, the multiplication of books containing the same information in almost identically the same manner to be an evil rather than a blessing. If an author has something new to say, or a simpler way of saying it, by all manner of means produce a book. We do not care one rap if nine-tenths of the work follows old lines; the new will commend itself and sanction the publication.

We are sorry that Prof. S. P. Thompson should have thought fit to call attention to his lectures, because if any man at the present time is answerable for the course pursued generally in teaching the subject, and condemned by Dr. Hopkinson, that man is Prof. S. P. Thompson. His "Elementary Lessons in Electricity and Magnetism" must be taken to express his views as to the course to be followed in teaching, and the first chapter of that book deals with "frictional electricity." Referring to this book in our issue of March 29 last year, we said "we entirely disagree with his teaching in the earlier lessons of this book." The most eminent men cannot expect to know every subject, and most emphatically Prof. S. P. Thompson is not to be congratulated upon his knowledge of "frictional electricity." Now that he hastens to admit Dr. Hopkinson's contention, we trust he will change the contents of the first part of his book in future editions. As regards Prof. Ayrton's book, "Practical Electricity," it hardly comes into the category of an ordinary school-book.

Digitized by Google

Each of these authors has something new to say and a new way of saying it, so that their books are welcome. In America a few authors have cast aside the old ways and started on lines very much like those suggested by Dr. Hopkinson. He, though not in so many words, says that theory should be taught from practice, and that the historic development of the subject is a waste of time. Nine-tenths or more of the views held even fifty years ago have been swept aside by the wonderful practical developments of the past quarter of a century. As improvement has succeeded improvement in the workshops, all of us have had to more or less modify our views to meet the new requirements. Dr. Hopkinson points out that the practical applications of electricity are from the discoveries of this century, and that these are almost wholly connected with what we may call current electricity and not with static electricity; hence the science should be taught through current electricity rather than through the antiquated notions about frictional or static electricity. Dr. Hopkinson sums up his views in the following pregnant sentences, which we trust will be re-echoed by every teacher in the kingdom, and that a real effort will be made to give effect to views undoubtedly correct: "There can be no doubt that the science could be easily rearranged, and that the phenomena of electromagnetism could be made fundamental, and that the facts concerning permanent magnets could be made subsidiary thereto, exactly as we have deduced this evening the facts of electric attraction from the phenomena of current electricity. I believe that in the future this is the way the science must be arranged for practical men. They are but little concerned with the attractions between charged spheres and the like, and very much concerned with the laws of currents and differences of potential and capacities. The theory of permanent magnets has for the modern electrical engineer only a general interest, but the laws of magnetic circuits and induction therein are all-important. It would seem that the subject needs rearranging, and that that which is most important should be put prominently forward. I even venture to think that this would be no loss to pure science; we should see with increased clearness how little we know what electrical phenomena really are, and how much we know of how electrical laws work. We shall see how much there is that is arbitary and conventional, and by no means absolute, in the system of units we have adopted. The science of electricity is so essential to the practical electrical engineer that it should be arranged so that he can learn in logical order what he most wants to know."

SOUND CASTINGS FOR ELECTRICAL WORK.

BY WALTER J. MAY.

Although, as a rule, electrical engineers are not much concerned with foundry work, they yet have very considerable interest in having sound castings for many of the appliances used in their work, and freedom from outside faults such as "blowholes" or flaws is not the only thing necessary. To have iron possessing equal resistance or conductivity—it matters little from which point our deductions are made—it must be of the same texture throughout, and should possess the same degree of homogeneity in all parts after the skin of the casting has been removed, and to secure this the iron must be clean. The writer uses more or less scrap iron for fine castings, and often has parts of electrical machinery sent in. As a rule these are good castings so far as outside appearance and quality of iron may be concerned, but many show that the iron is not too clean when broken, very many fractures showing that some amount of sullage or slag is in the iron, and this very largely alters the structure of the metal. Great care is no doubt taken in the foundries to ensure as uniform a quality in the metal as possible, but still the almost impossible removal of the sullage or dirt does not in all cases appear to be overcome.

Practically speaking, all small castings, or those having small or complex parts, have to be poured while the metal is very hot, this being done to secure fluidity; and, needless to say, there is no time lost in transferring the molten metal from the cupola to the moulds, as otherwise it would not run with sufficient freedom to fill all interstices of the moulds. This renders it very difficult to get the metal clean and free from sullage, and the result is that the casting is not of equal texture throughout. Although difficult to deal with, yet this point is one which is not insurmountable, as given time in which the sullage can rise while the metal retains its fluidity, the whole mass of metal becomes of even quality, and no trouble as to difference of structure will occur. To secure the necessary fluidity, metallic lead is sometimes used, while in some other cases aluminium has the preference; but neither give such good results as ferro-sodium, as this latter both increases the fluidity of the molten metal and by its action brings the whole of the dirt and sullage to the surface of the ladle, where it is easy of removal. The action of ferro-sodium is to maintain the metal in a more hot and fluid state than could otherwise be obtained, and time is thus gained in which the purification of the metal can take place, which is by no means an unimportant factor.

In the resultant castings made from iron fluxed with ferro-sodium it will be found that the iron is kept clean and uniform, and that externally it is free from blowholes or flaws of any kind. It can be filed, turned, or otherwise tooled with the greatest facility. In fact, ferro-sodium is just *the* thing for engineering castings of all kinds, and particularly for electrical castings.

Being a comparatively new fluxing medium, it may be well to mention that its cost is small, and would not in any way increase the cost of the castings. There being fewer wasters made, the balance would be in favour of the iron-founder rather than against him, as in all foundries wasters form a very considerable item of expense, and often delay in the delivery of the work.

THE ARC LIGHT.*

BY PROF. SILVANUS P. THOMPSON, D.SC., F.R.S.

LECTURE II.

(Concluded from page 74.)

The Trotter Phenomenon.

I now come to the most recent and by far the most important of recently-discovered arc phenomena. Mr. A. P. Trotter has observed a phenomenon in the arc which has so completely changed one's ideas as to the nature of the crater surface, that one needs to reconsider everything previously learnt or observed.

When you project upon the screen by means of a good acromatic lens (such as a camera lens) an image of the arc, and adjust it so as to get a good view of the crater, a little care will enable you to discern, as often as not, somewhere in the middle of the luminous crater—not always exactly in the centre—a nebulous patch, sometimes extending in different directions. This patch is more luminous than the surrounding surface of the crater, over which it moves in a capricious way. Sometimes you can catch a glimpse of this patch revolving, flickering round and round; sometimes it goes round one way and sometimes the other. You cannot readily observe it, however, unless you resort to artificial means, because of the rapidity of its motion. So to see it you must have recourse to the stroboscopic method. Take a simple disc of cardboard 8in. or 10in. across. Cut in this a number of equidistant narrow radial slits—say 36, 48, or

* Cantor lectures delivered before the Society of Arts.

Digitized by Google

60—and blacken the disc to obviate stray deflections. Put a pin through the centre, and fix the pin into a wooden handle. Spin the disc by hand, and watch the arc through the slits. You will then, at moments when the frequency at which the discs pass the eye corresponds to the rapidity at which the movements in the arc occur, catch sight of the moving object. A second method, suitable for projection of the phenomenon on the screen, is to mount a similar disc upon a small electrically-driven motor right in front of the arc. A suitable frequency is 400 per second or so. A third method of observation consists in throwing the image of the arc not upon a stationary screen, but upon a revolving disc painted half black, half white.

By the use of each of these methods Mr. Trotter succeeded last summer in proving that in the arc there is a phenomenon of rotation of something the precise nature of which is not yet known. The discovery was communicated in due course to the Royal Society. The essence of the stroboscopic method is that it gives a stationary or slowly moving view of a rapidly moving object. If a thing is revolving so fast that the eye cannot follow it, it may be readily seen if the observer is furnished with an apparatus which will allow the eye only to catch a momentary glimpse once in each revolution. Suppose that just at the instant when one slit passes the eye the revolving thing is in a certain position, and that by the time the next slit has come opposite the eye, the revolving thing has gone exactly once round, the eye will see it as though it had not moved. If the frequency with which the slits pass the eye does not precisely correspond, the revolving object will seem to revolve slowly, either forward or else backward, according as the frequency is either too small or too great. The thing that Mr. Trotter has found in the arc is a white object, having a sickle-shape or comma-shape, extending from some place near the middle of the crater to its edge, and revolving in a singularly capricious manner. The wandering whitish spot that is seen without the use of any revolving discs is apparently the head of the comma-shaped object, the tail of which moves usually so fast that its form cannot be seen, except by the use of the revolving slits.

By the kind co-operation of Mr. Trotter I am able to show you this rotatory phenomenon. An arc lamp arranged to be hand-fed is enclosed in a box. In front of the lamp is a small lens to throw an image on the screen and immediately in front of the lens is a rotating disc of tinned iron, provided with slits, mounted upon the shaft of a small but rapidly revolving electric motor. The slit disc as it revolves cuts off the light and restores it intermittently. We can vary the intermittences from 200 to 400 per second by changing the speed of the motor. What we have to do is to project a well-formed image of the crater upon the screen, and watch it while the rotating disc gets up speed, until the right speed is attained. We then see a sickle-shaped white patch (Fig. 20), which appears to rotate

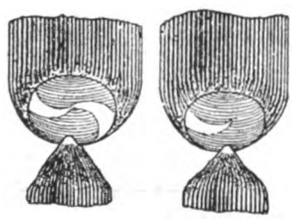

FIG. 20.

slowly backwards or forwards about a point as centre, or to stand still, according as the rotating slits go too quickly or too slowly, or keep in perfect synchronism with it. It usually has its centre in the middle of the crater surface, and extends to the edge. It is at the present moment in very rapid rotation; now it apparently decreases its speed, and stops for a moment, so that its shape is clearly visible. It appears as though the luminous part of the crater were shaped like the blade of a chaff-cutter, and whirled round with great rapidity. Now it changes its direction, and goes too quickly to be visible. Sometimes, when the speed of rotation of the object on the crater surface is only half as great as the speed of the disc, you get two views of the sickle-shaped object at opposite sides, forming a double figure (Fig. 20); and sometimes one gets a treble appearance or even four sickles meeting like a star in the centre. Supposing you have the rotation well developed, and then alter the current gradually, the speed changes in a perfectly regular way; and yet supposing there is a given current and the thing is going round at one particular speed all of a sudden, without any warning whatever, the direction of the rotation may reverse and yet keep the same rotary speed. When it reverses its direction of rotation it reverses its form also, the concave edge being always the advancing one. That is one of most puzzling things in the whole phenomenon. Apparently, with each current there is a particular speed of rotation that corresponds. The rotation is not a mere optical phenomenon of the surface of the crater, for, taking a lateral view of the arc and examining the flame part between the crater and the peak, Mr. Trotter has found evidence that the flame is itself, from top to bottom, also in a state of rapid rotation corresponding to what one sees in this white sickle-shaped body going round on the crater surface.

Interesting and puzzling as the Trotter phenomenon is, I fear it puts an end to the hope that the crater of an arc lamp might be used as a standard of light.

RECENT OBSERVATIONS BY MR. CROMPTON.

Mr. R. E. Crompton has lately noticed another arc phenomenon which was previously unknown, unless, indeed, it has been casually observed without the reason for it being known. It is the following: An arc may be burning perfectly steadily—of the proper length—everything going on without the smallest hint of any discontinuity, and all of a sudden, for apparently no reason whatever, the arc will enlarge itself, flaming out sideways, and the flame will go up round the upper carbon, and lick round it once or twice, and then everything will resume its former condition. Mr. Crompton observed this under the following circumstances. In order to study the feed mechanism of different lamps, and to find out which was doing its duty best, and also to study the properties of carbons with a lamp of any particular mechanism, he took records with a recording voltmeter of the difference of potentials between the carbons of the arc, and obtained a very large number of curves. If a recording voltmeter is put across the terminals of a lamp and the feeding mechanism sticks, you have a record of the fact by a slight kick in the curve. If the feeding mechanism stops and the feed does not take place when it ought to do, the arc will lengthen unduly, and the voltage across will rise, and that rise will go on for some time until the feeding mechanism does choose to work. As a general rule, a feeding mechanism which waits too long feeds too much. It overfeeds because it has waited too long, and down comes the voltage suddenly, causing a deal of irregularity before the steady condition of things is resumed. All this will be duly recorded in the irregularities of form of the curve drawn by the instrument. With a more perfect arrangement of feeding mechanism, you will have comparatively small changes in the voltage. Records of this sort enable an engineer to pick out that particular mechanism or to find the particular adjustment of mechanism which will give the most equable voltage on the lamp, and, therefore, obviously will cause the lamps to burn with the least flickering. Thanks to Mr. Crompton's kindness, I have here a number of these records. In this case the records are taken, not from a variety of lamps with different feeds (good and bad), but from a single lamp with a good feed. The object of this particular set of records was to study the different qualities of carbon in the same lamp. The first record shows a very even line; there are very slight undulations upon it; the feed was doing its duty; the carbon has got burnt down to a short stem and the rod had descended as far as the stop would allow it to; the arc became too long; the flame burnt itself out; the potentials rose until the arc broke, and the record stops in the middle of an up-stroke. The next record shows the same quality of carbon in use, but with two strange differences from the previous one. There are a number of small details which indicate that the feed was taking place at more or less regular intervals. It is a very fair curve, with a number of little nicks in it, which show that the feed had taken place rather more markedly than usual; but at two places in this record there is a great disturbance. In the middle of the comparatively quiescent line there is a sudden irregularity, which then settles down. Now, a great disturbance like that may be due to the following circumstances. The particular kind of carbon used was one which had certain impurities in it. All carbons have impurities, but this appears to have had impurities of a particular kind, whether silica, lime, iron, or what, I do not know. When the carbons were examined the following peculiarity appeared: Behind the crater, right up at the wide part of the conical surface, there accumulated, as there usually does accumulate upon the carbons of arc lamps, a brownish dust. In the present case, as soon as a sufficient quantity of dust had accumulated upon the base of the cone, the arc suddenly spread upwards, and like a good housemaid swept off the dust with a tongue of flame and then subsided, waited until a further aggregation of dust had accumulated, and then went housemaiding again. Among these records, several of which show this same phenomenon, there are some curious things, one of which illustrates the suitability or otherwise of a particular kind of arc lamp for use in a particular kind of building. In one case, where there are a number of cases of slight overfeeding, the record suddenly becomes very quiet indeed, the curve from that moment onward becoming almost a uniformly straight line. The record is marked as follows: "A to B tea-time, nobody walking about overhead." The lamp was suspended by a cord over a pulley, and the vibration of the building had caused the feeding to be a little irregular at times; but when there was no vibration the feed was more regular. It is not with all lamps that this occurs. Some lamps burn better in a building where there is little vibration to joggle the feed and prevent it waiting too long. Again, if a lamp is set to work at a certain voltage and then you use it at a voltage that is wrong,

Digitized by Google

you get irregularity. Here, for instance, is a lamp of which the record at 40 volts is a most beautiful straight line, there is hardly the slightest irregularity, but the same lamp worked at 52 volts across the terminals is highly irregular. There is a regularly recurrent irregularity in the action of the feed at this higher voltage. Again, another fact Mr. Crompton has observed by following out these records—viz., that if carbons are left in a damp place where moisture can be slowly and regularly imbibed into the pencils, such a carbon, even although of good quality, may give rise to great irregularities. Here is a very irregular record, for instance, obtained from an extremely good carbon, one of Hardtmuth's make. That same carbon taken out and dried in a stove above steam temperature for two days gives a record which has not a flaw in it. Apparently the warmth of the hot air ascending up from an arc is not sufficient to drive out from a carbon the moisture which has been slowly accumulating in it. It seems to be very necessary if you would have an arc burn with great regularity to keep your store of carbons in a dry place.

But this topic does not strictly belong to the optics of the arc—it relates rather to the question of the mechanism of lamps, which is the subject for my next lecture.

LECTURE III.

Mechanism of Arc Lamps.

In the six years that have elapsed since I had the honour of reading a paper on this subject before the Society of Arts in March, 1889, a great deal has been done to develop the mechanism of arc lamps. On that occasion there was circulated among the audience a schedule of the various parts of the arc lamp, or, rather, of the various things for which mechanism has to be provided. This schedule is now reproduced in a more extended form :

Schedule of Particulars of the.....Arc Lamp.

Nature of Supply..... ;
.....amperes ; .....volts at terminals.

Resistances.—Main circuit coil,.....ohms.
shunt coil,.....ohms ; cut-out,.....ohms.

A	Driving power	.....
B	Kinematic train	.....
C_1	Striking (electrical)	.....
C_2	,, (mechanical)	.....
c	,, adjustments of ...	.....
D_1	Feeding (electrical)	.....
D_2	,, (mechanical)	.....
d	,, adjustments of ...	.....
E	Moderating	.....
F	Replacement	.....
G	Focussing	.....
g	,, adjustments of...	.....
H	Change over	.....
I	Cut-out.....	.....
K	Cut-in	.....
L	Path of main circuit	.....
M	Path of shunt circuit.....	.....
N	Carbon-clamps	.....
O	Globe fittings	.....
P	Special features	.....

A few words of explanation are needed as to the meaning of some of the expressions used. By "kinematic train" is meant the particular mechanical device that holds the carbons from feeding until freed at the proper time. "Moderating" mechanism is instanced by the dashpots and the fan governors found in some lamps. "Replacement" refers to such arrangements as there may be for replacing the carbons when burnt out ; "change over" to the mechanism for bringing a second pair of carbons into play.

In nearly all modern lamps gravity is used as the driving power. The weight of the upper carbon in descending, or that of its rod or attachment, is in almost every case the motive power in the lamp for propelling the parts. The kind of mechanism or kinematic train that is employed seems to be gradually simplifying itself. In the former paper the typical varieties of mechanism in use were considered in detail. There was the rack, and the train of wheels driven by it ; there was a method of having a clutch or a clamp on a carbon-rod ; there was the method of employing a brake-wheel, or a clutch-wheel, so common in English lamps ; there was the method of feeding by means of a screw which could propel the carbons towards one another, or separate them ; there was the cord and pulley. Also there were certain other more special motions ; for instance, one very beautiful one, using a small electric motor to drive the carbon. Then there were various ways of arranging the "feed" to take place by vibration, or by some periodic action similar to the striking or chiming mechanism of the ordinary clock. There were attempts at making continuous feeds, so that the carbons should always be in motion slowly approaching one another, all the regulation needed being effected by the lamp itself, which altered the speed to make it a little quicker or a little slower when necessary. Then there were some hammering feeds employing a method of propelling the carbon, or something that held the carbon, by definite blows through the clutch which held the carbons apart. All these mechanisms persist, but some are much more favoured than others, in the lamps that have been introduced since that time.

Some Early Arc Lamps.

It may be convenient here to introduce a picture or two relating to the mechanism of lamps in general. The first will be a very old one, an invention of W. E. Staite, a man whom the electrical profession has never recognised as he deserves to be—one of the pioneers on the whole subject of electric lighting, and inventor in 1846 of the first automatic mechanism for regulating the arc. Staite produced not one but something like a dozen different forms of mechanism for lamps. In 1867 he had an arrangement equivalent in principle to some of those mechanical devices which have found favour of late. He fed the lamp from the bottom. The lower carbon was caused to be lifted up either by a weight going over a pulley with a cord fastened at the bottom or by a float. Fig. 21 shows the rod

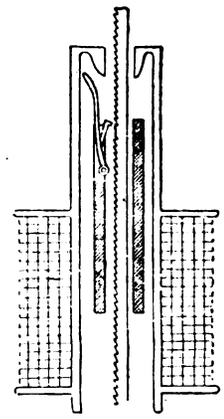

Fig. 21.

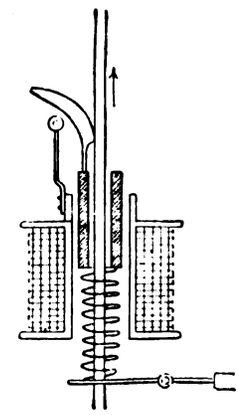

Fig. 22.

for holding the lower carbon, with ratchet teeth cut in it. These teeth are caught by a pawl pivoted to the top of an iron tube which surrounds the rod, the whole being surrounded by a series coil, which, when actuated by the main current, sucks down the iron tube against the constant upward force. As the carbon burned away and the current diminished by reason of the arc lengthening the tube slowly rises, and, of course, with it the clamp with its carbon. Presently the extension of the pawl is pressed against the inclined plane at the top, releasing the clutch, and the lower carbon is moved upwards. Another somewhat similar device which Staite had in 1852 is worthy of notice. In this case (Fig. 22) there was also a tubular core sucked down into a solenoid, the core being absolutely supported by a spring and a balance-weight. The rod passing through it was clamped by a peculiar clutch, the tail of which caught against a little wheel. The current in the coil, when turned on, pulled this down, pressed the curved arm against the wheel, and therefore pressed one end against the rod, and drew the rod down a little bit, so striking the arc. When the current in the main circuit became weakened, the curved brake-piece rose and released the carbon, which was allowed to slip up a little bit and feed the arc. It is a complete foreshadowing, only upside down, of some clutches which have been used in quite recent years.

(To be continued.)

INAUGURAL ADDRESS TO THE INSTITUTION OF ELECTRICAL ENGINEERS.

BY DR. JOHN HOPKINSON, M.A., F.R.S., PRESIDENT.

(Concluded from page 69.)

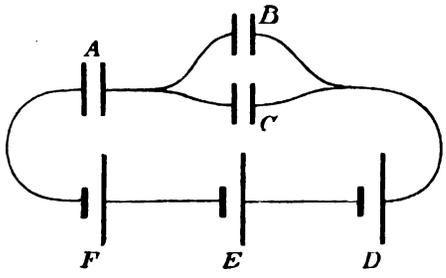
Let two plates of platinum dip into dilute sulphuric acid ; connect one plate by means of a wire to the zinc pole of a battery, the other plate to the copper pole. So soon as the connections are made, chemical reactions occur in the cells of the battery, the connecting wires are more or less heated, and, further, a reaction occurs in the vessel in which the platinum plates dip, the water is decomposed, gases are liberated on the two plates ; if these are collected, it is found that the gas from the plate connected to the zinc pole is hydrogen, that from the plate connected to the copper is oxygen. The effects cease on detatching either wire from the platinum plate or the pole of the battery, or otherwise interrupting the continuity of the circuit. In this experiment is seen a chemical reaction liberating energy in the cells

Digitized by Google

of the battery, and another chemical reaction absorbing energy in the vessel containing the platinum plates. How the energy passes from one vessel to the other we do not know.

The experiment may be varied. Let two plates of zinc or other metal dip into a solution of salt of zinc or other metal, and let the plates be connected to the poles of a galvanic battery for a time. If the plates be weighed before and after the operation, it is found that the plate which was connected to the zinc pole has gained in weight, and that the plate which has been connected to the copper has lost an equal amount. By weighing such plates, and noting the time the experiment was allowed to continue, it is practicable to examine quantitatively the phenomena of a galvanic circuit. Such pair of plates and solution of salt is called a "voltameter."

Suppose now a series of voltameters, having in each the same metal, are connected together in a chain, a plate of one to a plate of the next, and the two ends of the chain connected to the two poles of a battery, it is found that, no matter what be the size and form of the voltameters, their position, or the arrangement of the connecting wires, there is the same gain and loss of weight of the plates in all the voltameters; it is further found that, if the zincs of the cells of the battery are weighed before and after the experiment, and if the metal used in the voltameter be zinc, the quantity of zinc dissolved is the same in all the cells, and is the same is that transferred in each voltameter. The rate of dissolution and deposit is the same in the several voltameters and cells. In a closed galvanic circuit we have, then, a measurable something the same for all cross-sections of the circuit, measurable by the quantity of zinc or other selected metal which is transferred from one plate to the other of a voltameter in a unit of time. This something has direction as well as magnitude, and as the magnitude may be represented in terms of any unit chosen by a numerical quantity, C, so the direction may be represented by the sign + or −. It is arbitrarily chosen to take as + the direction from the plate which loses weight to that which gains weight through the liquid in the voltameter. The quantity, C, taken with its sign, is called the galvanic or electric current round the circuit, but it must not be supposed that it is known that there is anything flowing round the circuit.



Suppose that, instead of a simple galvanic circuit, the circuit divides or branches as indicated in the sketch, in which A, B, C are voltameters, F, E, D the battery. It is found that the quantity of zinc moved in B, together with the quantity of zinc moved in C, is equal to the quantity moved in A. This gives us the idea of current in the branch B or C, and we may say that the current in A is the algebraic sum of the currents in B and C. Not all bodies are competent to complete a galvanic circuit. Thus, if the copper wires which serve to connect the poles of the cells of the batteries and the voltameter are any of them replaced by thread, the phenomena of galvanism do not occur; if one of the wires be severed and a piece of paraffined paper interposed, the phenomena do not occur. Thus we have a distinction of substances into those which are capable of forming continuously part of a galvanic circuit and those which are not; the former are called "conductors," the latter "non-conductors." The distinction will be found to be really one of degree.

Consider a wire forming part of the galvanic circuit: after a short time no change occurs in the wire; it is heated by the current, and it loses heat by heat conduction, convection, or radiation. It is possible by the methods of calorimetry to measure the total quantity of energy leaving the wire as heat by these agencies; it must be equal to the quantity of energy brought into the wire by galvanic agency. Again, consider the battery itself. A certain chemical reaction is going on; zinc is being oxidised, and other reactions are occurring. Of the net amount of energy liberated per second by these, some goes to heat the battery, but some also appears in parts of the circuit external to the battery—that is, leaves the battery by galvanic agency. Thus a galvanic current is an instrument which takes energy from certain parts of the circuit and takes it into other parts of the circuit; and when the current is steady the algebraic sum of the quantity of energy taken into all parts of the circuit is nil. Denote by E C the quantity of energy per unit of time taken into any section, A B, of the galvanic circuit, the positive direction of the current being from A to B. If the whole of the circuit be broken into sections, the algebraic sum of the values of E C is nil, but the value of C is the same for all sections, hence the algebraic sum of the values of E is nil. Let there be any quantity, V_a, referred to each point of the circuit, such that $V_a - V_b = E$, the condition that the sums of the values of E shall be nil is fulfilled. E is therefore properly described as the difference of two quantities, one peculiar to A, the other to B; it is called the difference of potential between A and B, and V_a is called the potential at A, though it is only with differences of potential that we are concerned. Suppose now the circuit divides at A into two or more branches, joining again at B: by our definition the difference of potential between A and B is the sum of the energies taken per unit of time into the conductors, A B, divided by the sum of the currents in the conductors, A B. We have now to show that the energy taken into each of the conductors, A B, is equal to the difference of potential between A and B multiplied by the current in that conductor. This is by no means obvious, but depends on an assumption of an experimental truth—viz., that in a given conductor the energy taken into it by the current is a function of the current only, and is independent of other conditions external to the conductor. Granted this, it easily follows that if two or more conductors be joined at A and B, the potential difference between A and B deduced from each will be the same. As we have defined difference of potential by means of work done in a conductor when a given current exists in it, the laws of resistance must have the same basis. In the case of a homogeneous metallic conductor under given constant physical conditions of temperature, stress, and magnetic field carrying a constant galvanic current, C, Joule found that the heat liberated per unit of time varies as the square of $C = R C^2$ when R is a constant relative to C for the conductor. Whence follows that $E = R C R$ is called the electrical resistance of the conductor. For metallic conductors R is constant, but the constant R does not exist for all conductors; for the electric arc, for example, the heat generated varies more nearly as C than as C^2, and therefore E is more nearly constant than varying as C.

We have now gained two fundamental ideas—that of galvanic current and difference of potential. In terms of what units are we to measure them? We have only one unit to choose, because E C must be expressed in terms of our mechanical unit of power. If a unit were to be fixed at this stage, it would be natural to define either a unit of current or of resistance the ratio of $\frac{E}{C}$. For example, we might say the unit of current shall be that current whereby a unit weight of distilled water is decomposed per second; or, we might say, let the resistance of a piece of wire of defined shape and material at a definite temperature be the unit of resistance. The units in general use have an electromagnetic basis, but be it observed that all rational systems must be such that E C is expressed in some ordinary mechanical units. We have supposed that galvanic effects are measured by chemical change, and that the rate of galvanic effect—or, as it is generally called, the electric current—is measured by the rate of chemical change. From a theoretical point of view it would be possible to thus measure electric currents; but for practical purposes other means are adopted—electrometers, galvanometers, electro-dynamometers, and the like. With a description of such instruments and their methods of use I have not the time to concern myself this evening. We must assume that we have the means of measuring C, the galvanic or electric current so called, at any instant, and E, the difference of potential, whether these be great or small, and with any desired accuracy.

We should now be in a position to give a detailed account of galvanic batteries and of electrolysis, and the theory of the distribution of currents in systems of conductors of any form, and we are in a position to place the theory of thermo-electricity upon a thermo-dynamic basis without the introduction of any fresh idea. These, however, I leave on one side, and hasten to consider how the phenomena of electrostatics can be based upon what we have been discussing. There is a broad group of facts very familiar to the practical electrician engaged in laying telegraphic cables of which I have as yet given no account: I refer to the phenomena of capacity. Let us examine a little more closely the statement that I made, that if a slip of paraffined paper were interposed between the two parts of a conductor no electrical action would occur. Suppose that, instead of paraffined paper interposed between the ends of a wire, we have a very large number of sheets of tinfoil separated from each other by paraffined paper in such wise that we have a great area of tinfoil connected together, and separated from another great area of tinfoil by nothing more than the paraffined paper. If now these two areas of tinfoil are suddenly connected to the poles of a galvanic battery, we find that it is by no means true that no galvanic effect will ensue; we find that a galvanic current exists, but that, whilst it begins with a large quantity, this quantity goes on diminishing until, barring the slight imperfection of insulation of the paraffined paper, it becomes nil. We find, hen, that it is not true to state that paraffined paper cannot

Digitized by Google

form a part of a galvanic circuit; it can form a part of a galvanic circuit, but it does so under completely different laws to the metallic conductor. With the metallic conductor the difference of potential at its two ends depends only on the current which then exists in that conductor, and not at all upon the currents which have previously existed; with paraffined paper, on the other hand, the difference of potential between the sheets of tinfoil depends not at all upon the then current, but entirely upon the currents which have existed since its two coatings were connected together, and the times for which they have existed. A galvanic current may be measured by the rate of electrolysis; being measured by a rate, its time integral will have a perfectly definite meaning, and will be measured by the total quantity of substance which would be decomposed in a voltameter in the circuit. We find that the difference of potential between the two coatings of the paraffin condenser is proportional to the time integral of the current since the time at which the coatings were connected together last. The constant ratio of this time integral of current to the difference of potential is called the "capacity" of the condenser. Suppose now that the condenser has been connected to a galvanic battery and the time integral of the current has been measured; let now the coatings of the condenser be disconnected from the battery and be connected together through any instrument for measuring the time integral of current: if this is accomplished with sufficient rapidity for loss by imperfect insulation to be negligible, we find that the time integral in the second case is equal and opposite to that which it was in the first. Here, again, is a difference from conduction in the ordinary sense. If a conductor in which a current has existed be disconnected from the source of current and be connected to any measuring instrument, no return current will be observed. Here, then, we have a new order of facts presented in an extreme case, but, in fact, applicable to all kinds of insulators. Suppose we diminish the area of surface of the paraffined paper, we diminish *pro rata* the capacity of the condenser; but even when the paraffined paper is merely interposed between the ends of two copper wires it still will be a condenser having a definite capacity. There is no need to use paraffined paper to form a condenser. Two metallic plates may be insulated and placed parallel to each other. If they be connected one to one pole of a battery, the other to the other, a current will exist for a finite time. If they are now disconnected from the battery and connected to each other through a suitable instrument for measuring the time integral of current, a return current exists for a finite time. Consider now a condenser consisting of two parallel plates of very large area placed near to each other. It capacity varies as the area of the plates, and it also varies inversely as the distance between them—laws precisely analogous to those of conductors. It also, as might be expected, depends upon the material interposed between the two plates. Since the capacity of the condenser varies as the area, and inversely as the distance, whatever be the substance between the plates, there is a constant for every substance analogous to the specific conductivity of the material; this constant is called the "specific inductive capacity" of the material.

That the magnetic effects of the transient galvanic currents in insulators are the same as of corresponding currents in conductors is a fundamental law at the basis of Maxwell's theory of electromagnetism; it was, I believe, first definitely propounded by Maxwell, and it is one over which some of the most eminent minds have since contended. You will notice how, if the subject be arranged in the unhistorical, but not unnatural, way I have adopted this evening, this law drops so easily into its place that its assumption would be almost unnoticed. Why should we assume that the magnetic effects of electric currents in insulators and in conductors are different. By far the most natural assumption is that they are the same. Maxwell's electromagnetic theory of light—one of the great generalisations of the century—is directly based upon this law. What is this theory? It is simple enough in its character, broadly stated. Suppose you have an electrical disturbance, a transient galvanic current, in any dielectric, this disturbance—assuming the magnetic effects of currents in dielectrics to be the same as in conductors—will be propagated as a wave in directions perpendicular to the direction of the currents. The velocity of the wave can be calculated from purely electrical experimental knowledge; it is 3×10^{10}, if the dielectric be a vacuum. The velocity of light is 3×10^{10}. We know nothing of what light is; we do know that it is a wave, and that the disturbance is perpendicular to the direction of transmission of the light; but what is the ultimate nature of that disturbance we have no idea from the standpoint of the science of light. Is it not infinitely probable that the waves of light are none other than the electrical waves which we know must exist, and must be propagated with the observed velocity of light? And, mark, this theory demands no ether: it merely identifies the phenomenon of light with known phenomena of electricity and magnetism; it demands no knowledge of the fundamental nature of these phenomena: it demands only a knowledge of their laws. Surely Maxwell's generalisation is similar both in kind and in magnitude with the discovery of universal gravitation. Newton showed that the force which caused any body—an apple, if you like—to fall on our earth was the same as the force which kept the planets in their courses. He gave no theory of how that force was transmitted, nor of what, in its inmost nature, it was. He merely identified the two forces as one. So now Maxwell's theory may be shorn of all reference to an ether; it identifies as one the forces whereby light is transmitted and the forces with which we are familiar in our dynamo machines, and shows that they are measurably the same. It does not pretend to say what electricity and magnetism are, or what, if any, is the medium whereby the disturbances on which both depend are transmitted. Whether the postulate of an all-pervading ether be, or be not, a metaphysical necessity, surely it is well for the practical man and the physicist to leave the question to the metaphysician. My point, however, is that the hypothesis of two electric fluids and the ethereal theory of light have rather delayed than accelerated the acceptance of a great generalisation.

Let us now return to elementary matters. I have just stated that the capacity of two large plates near and parallel to each other varies as their area and inversely as their distance. In what units are we to measure capacity? If we have already chosen a unit of resistance, a unit of capacity must follow from that through the units of potential and current. It would be the capacity of that condenser which, if brought to unit difference of potential, would discharge a galvanic current whose time integral was unit current for unit time. It would be quite natural to define as a unit of resistance the resistance between opposite faces of a cube of a defined substance at a defined temperature, in which case the dimensions of resistance would be the reciprocal of a length. Or, again, we might lay by a piece of wire and carefully preserve it, and say, let that be our unit of resistance. Then resistance would have no dimensions in terms of mass, length, and time—it would be a fundamental unit. In either case we should introduce physical constants into our formulæ for electrostatic and electromagnetic phenomena, depending in the one case on the physical properties of the substance chosen, in the other on its actual dimensions. If the history of electrical discovery had followed the course adopted in this discourse, and it had become necessary to fix upon a unit of capacity at the point we have now reached, it would have been very natural to have taken the capacity per square centimetre of two plates at unit distance, the insulating medium being vacuum. We shall see shortly what is the actual electrostatic unit which has been chosen, but the fact is there is nothing specially natural, nothing specially absolute in the choice.

It is a matter of very great interest to know the capacities of condensers of various forms. Let us take, for example, the case of a sphere enclosed concentrically within another sphere. If r_1, r_2 be the radii of the two spheres, the result is that the capacity varies as $\frac{r_1 r_2}{r_2 - r_1}$; if r_2 be very great in comparison with r_1, the capacity varies as r_1. The electrostatic unit of capacity ordinarily adopted as absolute is the capacity of a sphere of unit radius enclosed concentrically in a very great sphere, with vacuum as insulator. From this, remembering that the product of a difference of potential and a galvanic current shall be power in ordinary mechanical units, all other units will follow. Thus time integral of current divided by difference of potential or capacity is a line; therefore, conductivity is a velocity, and resistance the reciprocal of a velocity. Difference of potential multiplied by current is power, and has dimensions $M L^2/T^3$, but potential divided by current has dimensions T/L; there current squared has dimensions $M L^3/T^4$, and current $M^{\frac{1}{2}} L^{\frac{3}{2}}/T^2$, and so on. Again, the capacity of two plates, area A, distance x, can be deduced from that of two concentric spheres at a small distance apart: it is $A/4\pi x$ in these units.

We may now prove that mechanical forces must exist between the plates of a charged condenser. Let a condenser be formed of two parallel plates of area A at a distance x from each other, the distance x being capable of variation; let the condenser be charged to a given difference of potential, and then insulated, and the position of the plates in relation to each other varied. If the condenser be then discharged, it is found, first of all, that the total discharge is the same however the position of the plates be varied. Suppose, now, that the condenser be charged to a difference of potential, E, and a quantity, or time integral, of current, Q, the work done in so charging the condenser will be $\frac{1}{2}$ E Q. Let now the condenser be insulated, and the distance of the plates increased to $x + \delta x$: the capacity of the condenser will be diminished in the ratio $x/(x+\delta x)$; and therefore, since the quantity remains the same, the difference of potential will have increased to $E(x+\delta x)/x$. Now discharge the condenser. The work done by the discharge will be $\frac{1}{2}$ E Q $(x+\delta x)/x$, or an amount of work $\frac{1}{2}$ E Q $\delta x/x$ greater than was done in charging the condenser. This work must come from somewhere. The only way in which it can be introduced is by the work done in separating the plates from each other. To increase the distance

Digitized by Google

between the two plates by an amount δx therefore requires that we shall do mechanical work $\frac{1}{2} E Q \delta x/x$ upon the plates. This mechanical work is done through a distance δx, therefore a force must be exerted in separating equal to $\frac{1}{2} E Q/x$; hence it follows, as a matter of necessary consequence from the laws of the capacity of conducting surfaces in the presence of each other, that those surfaces shall, when charged, act mechanically upon each other; and the amount of mechanical force is determined. Now $E . \frac{A}{4\pi x}$ is equal to Q, hence the force between the plates is $2\pi \frac{Q^2}{A}$. Let us now suppose that matter is laid upon each plate of density $\frac{Q}{A}$, and that the matter on one plate attracts that on the other plate with a force varying as the inverse square of the distance: the resultant attractive force between the plates is exactly $\frac{2\pi Q^2}{A}$; hence we should accurately express the facts of attraction of two plates if we said there is on each plate a charge of electric substance, and every particle of substance on the one plate attracts every particle on the other with a force varying inversely as the square of the distance. But that the facts can be so expressed is no evidence that any such electric substance exists.

I do not propose to touch on electromagnetic and magnetic phenomena. I would only point out this: just as electrostatics has been based on action at a distance between hypothetical electric fluids, so magnetism has been based on the action at a distance of hypothetical magnetic fluids. There can be no doubt that the science could be easily rearranged, and that the phenomena of electromagnetism could be made fundamental, and that the facts concerning permanent magnets could be made subsidiary thereto, exactly as we have deduced this evening the facts of electric attraction from the phenomena of current electricity. I believe that in the future this is the way the science must be arranged for practical men. They are but little concerned with the attractions between charged spheres and the like, and very much concerned with the laws of currents and differences of potential and capacities. The theory of permanent magnets has for the modern electrical engineer only a general interest, but the laws of magnetic circuits and induction therein are all-important. It would seem that the subject needs rearranging, and that that which is most important should be put most prominently forwaed. I even venture to think that this would be no loss to pure science; we should see with increased clearness how little we know what electrical phenomena really are, and how much we know of how electrical laws work. We should see how much there is that is arbitary and conventional, and by no means absolute, in the system of units we have adopted. The science of electricity is so essential to the practical electrical engineer that it should be arranged so that he can learn in logical order what he most wants to know. In what I have briefly indicated there will be something which is trite to all, and something perhaps not easy to comprehend when stated too shortly. My aim has been rather to excite in your minds discontent with the way in which the science of electricity is usually arranged in the hope that such discontent may take an articulate form, and become a demand for something more convenient for your particular purpose. When the demand becomes clear, it will not be long before it is supplied.

I am informed by Prof. S. P. Thompson that he has for some time past in his lectures begun the subject of electricity with the consideration of currents. My attention has also been called to Prof. Ayrton's excellent book on practical electricity, with the contents of which I ought to have been, but was not, acquainted, in which a similar arrangement of the subject was adopted no less than nine years ago. J. H.

January 22, 1896.

Prof. Silvanus Thompson, in moving a vote of thanks to the President, said that the address would mark an epoch and give a great stimulus to the advance of the science. He himself was one of those who had long thought that in electrical science they had allowed themselves to be too much bound by the methods and ideas of those who had preceded them. If they could manage to dispose of the antiquated law of last century and realise they worked under the law of the present century, not only would electricians be the gainers, but it would be a gain to science also. The views that had been expressed by the President that evening might be new to many present, but they were not new to all of them; and he (Prof. Thompson) could even have wished that the President might have seen his way to base the fundamental laws of electricity upon the dynamo, and not on the now antiquated galvanic cell In conclusion, he would remark that it was a source of great satisfaction to him to see that their President was among those who deemed it an honour to teach.

Prof. Kennedy, in seconding the vote, remarked that there were many members of the Institution who had passed a certain age, and who had necessarily learned the electricity of the last century. When these came to learn the new electricity, they found that there was a great gulf between the two. If the President had brought it about that that gulf should be more easily passed, or should no longer exist, he would have given great help to the electrical engineer and to the present Institution.

The vote was duly acknowledged by the **President,** who briefly referred to the short time which had elapsed since he had known that the honour and duties of president were to be placed in his hands and which must be his excuse for any shortcomings they might find in his address.

NORTHERN SOCIETY OF ELECTRICAL ENGINEERS.

PRESIDENTIAL ADDRESS BY W. P. JAMES FAWCUS.

I must sincerely thank you for the honour you have done me by electing me your president. To follow in the footsteps of my predecessor, Mr. Edmunds, is no easy matter, but my connection with this society from its commencement has been so intimate and my friendship with a large portion of the members is such that my task will be easier than it might otherwise have been. The Northern Society of Electrical Engineers is eminently a practical society, the whole of its members being actively engaged in their profession. You will therefore, no doubt, prefer me to confine my remarks to practical subjects.

In the first place, I must congratulate the society upon the extremely satisfactory progress it has made. The society was formed two years ago for the purpose of hearing and discussing papers on electrical engineering subjects, and also to give the members an opportunity of meeting together more frequently to discuss commercial questions. Both these objects have been attained, and the society has been supported in a manner which more than realises the expectations of the founders, all the leading electrical engineers in the district and many from a distance, some even from London, having joined our ranks and taken part in the proceedings. On January 22, 1894, the inaugural dinner was held. At that time we had already 107 members on the books; at the present moment we have 145 members and nine associates. Since the commencement of the society we have had read before us a number of papers, many of which have received very favourable mention on account of their practical character. We have also promised to us for this session a number of what I believe will prove to be most interesting communications. The society has served to bring together, to their great mutual advantage, many who might not otherwise have had an opportunity of meeting. It has, I believe, promoted a more healthy and friendly tone throughout the trade, and by constantly bringing together some who formerly looked upon each other only in the light of rivals has promoted friendships, and in many cases established commercial relationships and led to business being reciprocated between members of the society which would otherwise have gone elsewhere. I myself have experienced in no small degree the help and assistance of gentlemen whom but for the society I should not have known, at all events intimately.

There remains, however, in this direction much to be done. We still have working amongst us—though, I hope, not members of our society—many whose methods of obtaining business are by no means honourable or fair. Those who make false or misleading statements about the work of their competitors with a view to injuring them in their calling; those who by undertaking work at low prices, often using inferior materials and workmanship, cripple the business of others who are attempting to do good work at a fair price; those who with an insufficient knowledge of the work they are undertaking make mistakes costly to their clients and often disastrous to themselves—these it is who destroy the confidence of the public in the honesty of the trade and do much to retard the industry. It should be the duty of the members of this society to use collectively and individually all means within their power to discourage such conduct. During the past year, although there have been no remarkable new developments in our science, much solid progress has been made. To my mind electricity has hitherto been too much associated with sealing-wax and string, but I think we can congratulate ourselves that we now give as much attention to mechanical soundness as to electrical efficiency.

In electric traction it is satisfactory to see the large number of schemes which are in the process of development or in course of construction; there is little doubt that in the course of a few years the majority of the tramways in this country will be worked by electricity. The vast superiority of electric power for this purpose over either horse, steam, or cable traction has been amply proved at all events to the minds of all thoughtful electrical engineers, although no doubt much remains to be done in convincing many of our municipal authorities. The stumbling-blocks, so far, in the way of development in this direction have been the supposed unsightliness of overhead wires, and the imaginary difficulties in the use of conduit systems. In the former case the objections have arisen from the temporary character of the work of that kind in the States,

Digitized by Google

but the excellently-arranged systems recently inaugurated at Bristol and Coventry have already gone far to remove these prejudices, and in the latter case the successful working of the new systems in operation in the United States and on the Continent, and the inventive efforts at present being devoted to the subject, will no doubt shortly remove this difficulty also. It is very satisfactory to note that at Leeds both overhead and conduit systems are to be installed. The use of electrical transmission of power, especially in large works, is increasing rapidly, and I have no doubt a large amount of work, and, I hope, profit, will come to the industry from this source. Several demonstrations on a large scale have recently taken place of the saving to be obtained from this method of transmission, and the fact that these experiments have been satisfactory is proved by the number of enquiries now coming in from all sources to the leading firms in this country for power plants. In those branches we have, unfortunately, so far been much behind our Continental and American competitors, but the engineers of this country are now thoroughly in earnest, and it will be strange if we cannot recover our lost ground and outstrip our rivals, as we have done in every other department of engineering industry. Perhaps the most satisfactory progress made during the last 11 months is in electricity supply works; not only have a large number of new undertakings commenced their operations, in most cases with great promise of success, but established undertakings have enormously increased their load. It is also extremely satisfactory to notice the increase in the popularity of electricity as a heating and cooking agent. These uses will ultimately greatly help the day load, especially if wisely encouraged by means of favourable terms being granted for current used for purposes other than lighting.

We have recently had read before us a paper by one of our members (Mr. Manville), in which he described the scheme which the Corporation of Swansea has in contemplation for utilising their generating plant for working the tramways, and so providing a magnificent day load. It is expected that it will be possible to sell electricity for this purpose at 2d. per unit. Should this expectation be realised, the impetus given both to electric traction and electric lighting will be very great, and the combination of lighting and traction schemes will become general. New rules were recently drawn out by the Board of Trade for the regulation of electric supply undertakings, but as these rules would, in the opinion of most central-station engineers, have injuriously affected the industry, a large number of protests were lodged against their being put into operation without revision, with the result that the Board of Trade consented to hear the views of the objectors at a meeting held in London in November last. At this meeting, which consisted of the representatives of most of the corporations and companies owning electricity supply works, this society and the Institution of Electrical Engineers were represented; and I am glad to be able to report that the objections to the rules were met by the Board of Trade in a most reasonable manner, with the result that the new rules, when issued, while duly safeguarding the interests of the public, will not unnecessarily harass the undertakers.

A step of great importance to engineers, especially those having charge of continuous-current stations, is the introduction of high-voltage lamps. At the present time lamps are in use in several stations working at pressures of from 200 to 230 volts, and have proved themselves satisfactory when properly made. Those which have so far proved the best have two or more filaments arranged in series, no filament having to stand an abnormal pressure; made in this manner, it is possible to obtain a good lamp for 230 volts as small as 8 c.p., while a lamp of 16 c.p. can be made to run with pressures up to 400 volts. The possibility of obtaining lamps for such high voltages will no doubt induce engineers to gradually raise voltages within the premises of consumers, and here I should like to strike a note of warning. Although there may be no objection to using pressures up to 400 volts in public buildings or elsewhere when the installation is under experienced control and the fittings are inaccessible to the public, for private houses and ordinary business premises, where the inexperienced cannot be prevented from having access to the wires and fittings, 200 to 259 volts are quite high enough for personal safety. Even if there is no actual danger to life from the direct effects of a shock of from 250 to 400 volts—a question which is open to doubt—the indirect results of such a shock might be most injurious, or even fatal, if received by a delicate person or one in a dangerous position. It would be an evil day for the industry if through the occurrence of fatal accidents to the general public the electric light should again get the name of being dangerous, which, fortunately, it has now practically lived down. There is another reason why considerable caution should be exercised in converting existing installations from low to high pressures: the types of switches and other fittings commonly in use are totally unsuited to pressures much beyond what they were designed for, and in the case of some of the older installations, the insulation on the wires will be insufficient.

Attention has recently been drawn to the subject of life and efficiency of incandescent lamps by the tables and correspondence which have recently appeared in the technical papers on lamp tests. It is surprising how few of the public, or even of practical electrical engineers, take the trouble to learn anything about incandescent lamps, when by using a little knowledge on this subject it may often be possible to reduce the cost of lighting to one-half. It is possible for a lamp manufacturer to produce lamps to suit a variety of different conditions, provided he is made aware of them, but as he seldom is furnished with any particulars beyond the candle-power and volts at which the lamps will have to work. He frequently has his lamps condemned as bad, when in reality there is nothing the matter with them if used under proper conditions. In certain cases it may be desirable for the consumer to use a lamp which, although working at a comparatively low efficiency, will keep its full candle-power during its life; lamps of this type can easily be procured. In other cases it may be preferable on account of the cost of energy to use a lamp which will consume a minimum of current. In this case the consumer must be prepared to sacrifice either constancy of candle-power or duration of life. No lamp has so far been produced which combines a long life with high efficiency and constant candle-power. Again, it may be impossible to guarantee the regularity of the pressure at which the installation runs. Under these conditions an ordinary lamp would have a short life, but if the maker is made aware of them he can specially construct one suitable.

I have for the last few weeks been engaged on a series of experiments upon lamps of most of the leading English and Continental makers. During these experiments one or two interesting points, which may not be known to all of you, have come under my notice. I have observed in the case of many lamps commencing their life with an efficiency of about four watts per candle-power (a very usual efficiency), that in the course of from 100 to 150 hours' run the candle-power has increased as much as 20 to 30 per cent., and the watts from 15 to 25 per cent., and has then gradually fallen until the end of their life. Installers should bear this point in mind, as the use of such a lamp in an installation where the plant had not a fair margin of power might well lead to trouble through overloading. I have also observed that in some lamps commencing their life with an efficiency of from 2½ to 3 watts per candle-power, no rise, or, at all events, a very slight one, was observable in the candle-power at any period of their life, but a steady and fairly rapid fall from the commencement until a critical period is reached at between 300 and 500 hours when the lamps reach almost their minimum efficiency from 4 to 4½ watts per candle-power, and continue in this state for the remainder of their life, which in the case of some of the better lamps has averaged considerably over 1,000 hours. This would point to the advisability of using a high-efficiency lamp as such for a time, and subsequently moving it to a less important position for the remainder of its life, being content with about half its original light—it would then be no worse than an ordinary lamp of the lower candle-power. I hope in the near future it may be possible for supply undertakings to sell light to their customers, and not current. For only in this way will it be to the advantage of the engineer (generally the only person competent to come to a just conclusion) to see that the current is being consumed by suitable and efficient apparatus.

It is somewhat an unsatisfactory sign that so much foreign material is being sold in this country, and is in many cases introduced and encouraged even by those who are striving in other branches of the industry to compete against it. British electrical engineers are now entering on a critical period of their existence; they are being threatened on all hands by foreign competition, and unless they wish their business to get into the hands of the German they must not only strive to keep up the high reputation which English workmanship has always possessed, but must be prepared to support one another by reciprocating business and refusing to buy abroad when it is possible to obtain as good an article at home.

ALTERNATE-CURRENT TRANSFORMERS.

BY DR. J. A. FLEMING, F.R.S.

On Monday evening last Dr. Fleming gave the first of a course of four Cantor lectures on the above subject at the Society of Arts, John-street, Adelphi.

After alluding to a course of lectures delivered on the same subject three years ago, Dr. Fleming said that on this occasion he proposed to omit the elementary parts of the subject and address himself as a specialist to specialists. There were three kinds of transformers which might be discussed: the mathematical transformer, a beautiful and much-admired instrument; the contractor's transformer, the characteristic of which was its extremely high efficiency; and, lastly, the practical transformer in real use. This, with all its faults and phases, was the one he proposed to consider, in disregard alike of academical theory and faulty practice. The proper form of transformer was, it would be seen, a matter of considerable

Digitized by Google

practical importance when it was remembered that there were 47 alternating stations in the kingdom. The energy absorbed in hysteresis would be 40,000 kilowatts, if not more, from which it worked out that something like 8,000 tons of coal a year were employed in the magnetising many times a second an aggregate weight of cores amounting to 400 tons of laminated iron. A transformer might be regarded as an instrument by which an increase or decrease of current strength was purchased at the expense of a change of potential. It consisted of three organs: the primary circuit, the secondary circuit, and the magnetic circuit. The primary circuit was interlinked with the magnetic circuit, and this again was interlinked with the secondary circuit. By varying the relative number of linkages, electrical power in the form of a small current was changed into electrical power in a large current, with, however, some loss of power in the process. This was doing precisely the same thing as was done with mechanical power by a "simple machine," and they had in that case an exact analogy of the loss of electrical power in the loss by friction. After briefly alluding to the possibility of classifying transformers according to whether they had or had not iron cores, whether or not the magnetic circuit was complete, or, again, as step-up and step-down transformers, the lecturer said that just as the indicator invented by Watt showed what went on inside an engine cylinder, and was necessary for the theory of the steam-engine, so the theory of the transformer was imperfect and academic until a method was invented of delineating what was going on at each instant inside it. To do this it was necessary to have a means of ascertaining the instantaneous value of the potential at any moment between its two maximum values. If a condenser was connected to an alternator its potential would follow the same law as that of the alternator, and if it were suddenly disconnected it would remain at the momentary potential, which could then be measured. What was necessary was an arrangement making contact always at a given instant of the phase. The lecturer then described the apparatus used, the momentary contacts being secured by a small alternating-current motor running in step with the alternator. If observations were taken of the potential at short intervals from maximum to maximum, curves could be plotted of the E.M.F. either in rectangular or polar co-ordinates. The latter were of use as giving more easily the ratio between the maximum potential and the square root of the mean squares value, which was what is measured by a voltmeter. The name given to this ratio was the "form factor." A quantity of curves had been taken by Messrs. Morris and Pettivell in this way at the Bankside works, and the remainder of the lecture consisted of an exhibition of a large number of them, showing how their forms were affected by varying the load and the induction. For instance, it was shown that the Mordey alternator gave a smooth rounded E.M.F. curve both at no load and with a non-inductive resistance. If a Mordey alternator was coupled with a Thomson-Houston, the form remained essentially similar. But the Thomson-Houston alone gave a much sharper curve with higher maxima, so that the Mordey alternator impressed its own form of curve on the combination. In the Mordey alternator there was very little armature reaction, and the current curve corresponded closely to the E.M.F. curve, but in the Thomson-Houston it was much affected by altering the load and the shape of the curve being altered. Another point brought out was that the form factor must not be assumed in any case, since it depended on the load. The two curves might have the same mean value, but their maxima would be very different—a matter that must be carefully considered in testing cables. After further illustrations of the effect of induction and current lag on the form of the curves, the lecturer passed to the analysis of the curves by the mechanical harmonograph. It was found that nearly all the curves that were met with in practice could be analysed into simple sine curves whose frequencies were in the ratio of 1 : 3 : 5. Such a curve could consequently be completely represented by a chord composed of G (bass clef), D (between the staves), and B (treble), the vibration periods of which were 96, 288, 480 per second, and the intensity with which the notes were struck corresponding to the altitudes of the curves. Passing to curves taken from transformers, the lecturer pointed out that the curve of the transformer followed exactly the form of the primary curve. It had been said that the transformer wiped out irregularities. That was not the case. An experimental proof of this might be found in the telephone. The transmitter had in it an induction coil, yet the sounds were exactly reproduced, and therefore the wave form must be unaltered. After explaining the theoretical relation between the E.M.F. curve and the curve of magnetic induction in the core, it was remarked that in practice the magnetic circuits were not wholly interlinked with the primary and secondary circuits, so that the results obtained by integrating the induction of the primary and secondary circuits were not the same. Curves of hysteresis were next exhibited, though this subject was in the main left over to the next lecture on January 27, which will deal with hysteresis losses and the construction of the transformer.

LEGAL INTELLIGENCE.

THE EDISON AND SWAN TRADE-MARK.

At the Central Criminal Court on Monday, before the Common Serjeant, Edward Augustus Ingold (30), engineer, and Alfred Attride (34), a horse trainer, were indicted for falsely applying to certain lampholders a mark resembling the trade-mark of Messrs. Edison and Swan in such a manner as to be calculated to deceive. Mr. C. Mathews and Mr. C. F. Gill prosecuted, and Mr. Schullers Young defended Ingold, and Mr. Hutton and Mr. Collison, Attride.

Ingold at one time was in the employ of the prosecutors, and after leaving he became the London agent of a German firm, from whom he ordered in different names large quantities of electric light holders. The addresses given of the firms in whose names the holders were ordered were newsagents' shops or the private houses of the relatives and friends of Ingold. Having got possession of the holders, it was alleged that the two accused men proceeded to get them stamped. For a time, no doubt, they were stamped with a genuine stamp of a firm of licensees of the patentees, but the stamp was, unknown to the licensees, taken away from their premises by a workman who was afterwards dismissed. Attride, in the name of Ford, then induced a man in Clerkenwell to make a stamp and to stamp the articles. In disposing of them, the prisoner Ingold represented that he was acquainted with a bailiff who had taken the lampholders for a debt, and, with regard to the others, he said a dealer had bought a job lot for him. They were purchased in the belief that they were the genuine Edison and Swan holders.

In defence, it was urged that Attride, who was a rough rider engaged at the Aquarium, was an innocent agent in the matter and on behalf of Ingold it was contended that he had used the words "Edison and Swan patent," and that this was not a colourable imitation of the registered trade-marks "Ediswan" and "Edison-Swan" Complaint was also made that the firm had made this a criminal instead of a civil matter.

The jury convicted Ingold, but acquitted Attride.

George Cosgrave, 22, an engineer, pleaded guilty to a similar offence in falsely applying the trade-mark to the holders, and on the application of the prosecution was bound over in the sum of £100 to come up for sentence if called upon.

Mr. Mathews said Ingold had been the prime mover in this matter, and had confessed to having sold 13,000 of the holders. He had a further 3,000 on order, and on him were found orders for 4,000 and 5,000 more. It was he who had tempted the other men.

The **Common Serjeant** sentenced him to nine months' imprisonment without hard labour.

COMPANIES' MEETINGS AND REPORTS.

DIRECT UNITED STATES CABLE COMPANY, LIMITED.

The ordinary general meeting of the Direct United States Cable Company, Limited, was held on Tuesday at Winchester House, Sir John Pender, M.P., presiding.

The **Chairman**, in moving the adoption of the report, stated that the revenue for the six months ended the 31st ult., forming the first half of the Company's current financial year, amounted, after deducting out-payments, to £43,938. The working and other expenses, including income tax, but excluding the cost of cable repairs, absorbed £19,058, leaving £24,880 as the net profit for the half year, making, with the amount brought forward, a total of £26,290, out of which two interim dividends of 2s. each per share had been declared, and £10,000 had been transferred to the reserve fund, leaving £4,148 to be carried forward. The revenue, which had commenced to improve in the early part of last year, had still further progressed within the last six months, for which period it showed an increase of £5,596, or more than 14 per cent. as compared with that of the corresponding period of 1894. Nevertheless, their aggregate ordinary expenditure had been only £34 greater. The cost of repairs to cables had been heavier than usual, having amounted to £6,984, which had been charged against the reserve fund account as usual. On the other hand, the fund had been credited with £4,619 for interest on the investments, and with £10,000 from the revenue account, bringing the balance of the reserve fund up to £306,000. The investments had been increased during the half-year by £16,400, and their present market value was about £55 000 more than they cost the Company. They had considered it very advisable to keep up a good reserve fund. They were getting to the end of the twenty-fifth year of their existence as a cable company, and as they had put in a great many repairs during the last 12 months and the last two or three years, they would still find if they were thrown on their beam ends that they would be short of the amount required to give them a new cable; and therefore they had always to look ahead and take care that they were not caught sleeping. The six months they had just passed through had been rather exciting. They had had politics, and they had had a good many things going on in America which had caused some anxiety. But he still thought that common sense would prevail, and that a settlement of the question which was now being agitated in America would thus be arranged. He had received four letters from different shareholders who complained of the rate of dividend and desired to see it increased. He should be only too glad to recommend the payment of a higher dividend, and if things went on as well as at present he hoped they would be able to do so next time.

Digitized by Google

He found it was far more easy to declare a dividend than it was to get one back, and they had to look well ahead and keep everything in proper working order, but he thought he could promise something in six months' time more than they were giving now. During the past year it had cost £7,000 to repair the cables; one cable had been hanging on a rock in the Irish Sea for 22 years, and had at last been cut through, but they were now all in working order. They were working the duplex upon their system now, and they had not been working it for four or five years. Although they carried a large sum over to the reserve fund, they drew out of that reserve the amount required to effect the repairs.

Mr. E. M. Underdown, Q.C., seconded the motion.

A brief discussion followed, and, in answer to questions, the **Chairman** stated that they had adopted Muirhead and Taylor's recorder, and he was quite satisfied, having consulted Lord Kelvin and their own scientific men on the matter, that the Company possessed a very valuable recorder. When the duplex was working they did not require the same amount of speed as when it was not in operation, but when the duplex was not working the automatic transmitter gave them about 40 per cent. of additional speed, which was very important. Everything was uncertain with America at the present time, and if the Company had to cease working their revenue would be affected. It was better not to begin to pay a higher dividend until the way was clear. Their traffic at the present time was 17 per cent. in excess of that at the same period last year. Cables had lately been established which affected them, the additional lines being in excess of the requirements of the Atlantic traffic. The advice which had been given to them to sell their Consols was not, he thought, bad advice. He believed they had cost the company about 96, so that their realisation would give them a good profit. As to the injury which might be done to submarine cables in the event of war, he once endeavoured to get the Government to make an agreement by which the lines would be protected, but the reply he received was that the Government would agree to it at once, only the general who would be in command would break it. That was what they all feared. He, however, did not believe that cables would be deliberately broken if it could be helped, although they might be interrupted.

Mr. John Newton said he believed that the destruction on railways in time of war would be far more disastrous than any damage which could be done to cables. Cables could be stopped working by one effective cut, which could be easily repaired afterwards. He had never had the slightest apprehension that war would interfere with cable property beyond stopping the revenue for the time being of any particular cable.

The **Chairman** said that he was very much disposed to take the same view.

The motion was carried unanimously, and a vote of thanks to the chairman concluded the proceedings.

EASTERN TELEGRAPH COMPANY.

The half-yearly ordinary general meeting was held at Winchester House yesterday, Sir John Pender, G.C.M.G., M.P., presiding. The report of the directors stated that the revenue for the six months ended September 30, 1895, amounted to £409,779. 15s. 6d., from which are deducted £96,703. 19s. 7d. for the ordinary expenses, and £47,165. 2s. 7d. for expenditure relating to repairs and renewals of cables, etc., during the half-year. After providing £3,423 4s. 7d. for depreciation of spare cable, £821. 2s. 3d. due to revaluation of currency assets, and £5,748. 15s. 5d. for income tax, there remains a balance of £255,917. 11s. 1d., to which is added £1 252. 3s. 9d. brought from the preceding half-year, making a total available balance of £257 169. 14s. 10d. From this balance there have been paid: interest on debentures and debenture stock, £27,520. 11s 8d.; dividend on preference shares, £20,296. 5s 5d.; two interim dividends of 2s. 6d. per share each on the ordinary shares, £100,000; making a total of £147,816 17s. 1d. After carrying £10,000 to the reserve fund for maintenance of ships and £50,000 to the general reserve fund, there remains a balance of £49,352. 17s. 9d. which is carried forward to the next account. The revenue includes £25,447. 14s. 2d., dividends for the half-year upon the Company's shares in the Eastern and South African, the Black Sea, the Direct Spanish, and the African Direct Telegraph Companies.

CITY AND SOUTH LONDON RAILWAY COMPANY.

Directors: Charles Grey Mott, Esq. (chairman), Harrow Weald, Middlesex; Charles Seymour Grenfell, Esq., Elibank, Taplow; Sampson Hanbury, Esq., Wyvenhoe Park, near Colchester; S. Barclay Heward, Esq., 96, Ashley-gardens, Westminster; Edwin Tate, Esq., 21, Mincing-lane, London, E.C.

Report of the directors, with abstract of accounts for the half-year ending December 31, 1895, to be submitted to the half-yearly ordinary general meeting of the Company, to be held at Winchester House, Old Broad-street, E.C., on Tuesday, Jan. 28, 1896, at 12 noon:

The receipts from all sources for the past half-year have amounted to £24,554. 9s. 2d., and the cost of working has been £14,638. 16s. 4d., leaving a profit of £9,915. 12s. 10d. Inclusive of the balance brought forward from December 31 last, the net revenue account shows an aggregate total of £10,922. 7s. 4d. After making provision for the debenture and debenture stock interest, a balance remains available for dividend of £7,111 7s. 1d. Out of this sum your directors recommend that the full dividend of 5 per cent. per annum be paid on the preference shares, and that a dividend at the rate of 1¼ per cent. per annum be paid upon the consolidated ordinary stock, leaving a balance of £1,219. 16s. 1d. to be carried forward to the next account. The following table shows the number of passengers, exclusive of season-ticket holders, carried since the opening of the railway in each half year:

Half-year ended	Number of passengers (exclusive of season-ticket holders).	Receipts (including season tickets).
Dec. 31, 1890 (11 days)	165,000	£1,568 3 9
June 30, 1891	2,412,343	19,403 6 9
Dec. 31, 1891	2,749,055	19,798 16 6
June 30, 1892	2,813,162	20,931 4 2
Dec. 31, 1892	3,117,602	22,002 17 5
June 30, 1893	3,146,656	22,458 6 9
Dec. 31, 1893	3,093,351	22,067 14 10
June 30, 1894	3,383,154	23,564 10 6
Dec. 31, 1894	3,275,649	23,540 12 4
June 30, 1895	3,113,199	23,711 5 8
Dec. 31, 1895	3,172,438	23,780 3 7
Total since the opening of the line	30,441,609	£222,827 2 3

During the summer quarter of the past half-year the traffic of the line was considerably diminished by the unusual and prolonged heat which then prevailed, and since that time the traffic of the line has suffered from the entire closing of the Oval for football matches, but notwithstanding these drawbacks there is an increase in the receipts, and this is especially noticeable in the item of season tickets, which indicates the steadily-growing confidence of the public in the convenience, safety, and punctuality of the line. In regard to the extension of the line to Finsbury-pavement, your directors have the pleasure to state that most satisfactory arrangements have now been entered into in respect to the more important properties required, and are such as justify them in fully believing that the proposed extension can be carried out within the estimate named in their report of January 22 last, approved by the shareholders at the half-yearly meeting on February 1 following. Preparations are therefore being made for carrying out the extension without delay, and the proprietors will be asked at the extraordinary general meeting called for that purpose, out of the capital of the Act, 1893, to be then created, to sanction the issue of 20,000 5 per cent. preference shares of £10 each, which it is estimated will be sufficient to provide the amount required. It is intended that in the issue of these shares, arrangements shall be made that no charge will fall upon revenue in respect to the dividend upon them, until after the time at which it is estimated the extension will be open for traffic, and earning a larger sum than will be required for that purpose. The alterations at King William-street Station, to which reference was made at the last meeting, have occupied a longer time than was expected owing to the necessity of avoiding interference with the existing traffic, but they are now completed, and will be brought into use in the course of a few days. The difficulty of dealing with the morning and evening traffic still continues, involving a considerable loss of revenue, but it is hoped that the additional trains which these alterations will accommodate will enable the press of traffic at those times to be better provided for. The additional sidings at Stockwell referred to in the last report are now finished, and will add greatly to the convenience of the working of that station. In view of the increased number of trains to be run, seven additional carriages have been ordered, and an additional locomotive built in the Company's own shops is nearly completed. The generating plant, which is in good working order and repair, has been materially strengthened by the erection of a small engine and dynamo, which will effect a decided economy in working the traffic in the less busy part of the day. An order has also been given for the erection of a condensing apparatus at the generating station, which it is anticipated will make a considerable reduction in the quantity of coal consumed. During the past six months a further sum of £9,400 terminable mortgage debenture bonds has been paid off. As the powers of the Company for the compulsory purchase of lands in connection with the Act of 1893 will expire in August next, application is being made to Parliament for a further extension of that time. In the same Bill powers are sought for the acquisition of a site for a temporary shaft in the High-street, Borough, with the view of saving expense in the construction of the junction of the new extension with the existing tunnels. This Bill will be submitted to you at the special general meeting of which notice has been given. The engineer of the Company, Mr. Basil Mott, having resigned his position in order to take up an appointment in connection with the construction of the Central London Railway, Mr. P. V. McMahon, who has acted for some years as assistant engineer, has been appointed to succeed him. The directors retiring by rotation are Messrs. Charles Seymour Grenfell and Edwin Tate, who are eligible and offer themselves for re-election. Mr. James Loriner Oliver is the auditor to retire on this occasion and is eligible for re-election.

CONTRACTS FOR ELECTRICAL SUPPLIES

CONTRACTS OPEN.

Parma (Italy).—The municipal authorities of the city of Parma desire tenders by February 25 for the electric lighting of the city from June, 1897, to 1912.

Cattowitz.—Tenders are invited by January 29 for the supply of carbons for arc lamps at the railway. Particulars from the Königl Eisenbahn-Direktion (Room 7 of the Administration Building), Cattowitz, for 50pfg (6d.).

Soria (Spain).—Offers are wanted for the concession of the electric lighting of Soria for 20 years on the basis of an annual payment of 9 000 pesetas. Particulars from the Municipal Offices Soria, where tenders must be sent by January 30.

Teneriffe (Canary Islands).—Tenders are invited for the electric lighting of the town of Santa Cruz, Teneriffe, for a period of 35 years. Particulars can be obtained at the Ministerio de la Gobernacion, Madrid, and tenders must be delivered by February 29.

Aussig.—The communal authorities propose to have built a seven-mile single line tramway. The choice of system is left open Contractors are invited to place themselves in communication with the Stadtrath, Aussig-a.-d.-Elbe, Prussia. Tenders are to be in by January 31.

Swadlincote.—The Swadlincote Urban District Council intending to light the township of Stanton with electric lighting, invite tenders for the work. All particulars can be obtained from Mr. R. Cartwright, surveyor, Swadlincote, to whom tenders must be sent by 27th inst.

Paris.—Tenders are asked for the supply of 500,000 kilogrammes of galvanised wire and various telegraphic supplies for the State telegraphs. Application for permission to tender must be made by February 3 to La Direction Générale des Postes et Télégraphes, Rue de Grenelle 3, where particulars may be obtained.

Ramsgate.—Tenders are invited for electric lighting at the Promenade Pier, Palace of Varieties, and Marina Restaurant, for the Ramsgate Marina, Pier, and Lift Company, Limited. No specification has been prepared, but particulars of what is required can be had on application to the Secretary, 23, Martin's-lane, Cannon-street, E C.

Lindley (Huddersfield).—Tenders are invited for the electric lighting engineer's work required at Zion Methodist New Connexion Chapel, Lindley, Huddersfield. Drawings and specifications are at the offices of Messrs. John Kirk and Sons, architects, Huddersfield and Dewsbury. Sealed tenders are to be sent to the architects by 3 p.m. on the 29th inst.

Huddersfield.—The Electric Lighting Committee of the Corporation invite tenders for the supply of two steam-boilers, four mechanical stokers and one surface condenser, with air and circulating pumps. Specifications and forms of tender may be obtained of Mr. A B Mountain, borough electrical engineer, St. Andrew's-road, Huddersfield. Tenders, endorsed "Tender for Electrical Machinery," must be delivered to the town clerk, Town Hall, Huddersfield, by February 4.

RESULTS OF TENDERS.

London, S.W.—The Guardians of Chelsea have accepted the tender of Messrs. Graham and Biddle, at £338. 12s. 6d., for fitting up an electrical wiring installation with fittings in the infirmary.

Colchester.—The War Office has placed the contract for the internal wiring and fittings for the electric lighting of the new military hospital at Colchester with Messrs. Paterson and Cooper, Dalston, N.E.

BUSINESS NOTES.

Kirkcaldy.—The Town Council have appointed a committee to enquire into the question of introducing the electric light.

Castleford.—The Urban District Council are considering the advisability of lighting the streets and market by electricity.

Clontarf.—The Township Commissioners have approved of the electric tramway scheme submitted by the Southern District Tramways Company.

Swansea.—A resolution has been passed by a ratepayers' meeting authorising the promotion by the Corporation of the Bill for the purchase of the tramways

Dover—At a meeting of the Working Men's Institute an almost unanimous vote was given in favour of the Corporation providing tramways worked by electricity.

City and South London Railway.—The returns for the week ended January 19 were £1,004, compared with £996 for the corresponding period of last year, being an increase of £8

Llandrindod.—A special meeting of the Urban District Council has been summoned to consider the question of an agreement with Mr. S Jevons for lighting the street lamps with electricity.

Western and Brazilian Telegraph Company.—For week ending January 17, the receipts, after deducting 17 per cent. payable to the London Platino Brazilian Telegraph Company, were £2,915.

Maidstone.—The proposal to transfer the powers of Electric the Lighting Committee to a company promoted by Mr. Thomas King, has been deferred to the next meeting of the Urban District Council.

Dundee.—The Court of Directors of the Royal Lunatic Asylum think the time is rapidly approaching when they would be required to deliberate as to the introduction of electric light into the buildings.

Wimbledon.—The Urban District Council have decided that application be made to the Board of Trade for an extended license for such period as will enable the Council to obtain a provisional order for electric lighting.

Hampton.—The District Council have decided to request an electrical engineer to give an opinion as to the probable cost of lighting the district with the electric light if the cables were laid at the same time as the sewers.

Liverpool Overhead Railway.—The traffic receipts of this railway for the week ending January 19 amounted to £1,172, as compared with £900 in the corresponding week of the previous year being an increase of £272.

Pembroke.—The Town Council have resolved to give the Pembroke Ward power to introduce electric light. Motive power will be supplied by a Pembroke mill-owner, and Mr. J. T. Ford is going to lay down plant at his own risk.

St. James's and Pall Mall Electric Light Company.—The directors recommend a dividend at the rate of 10½ per cent. per annum on the ordinary shares for the half-year ended December 31, making, with the interim dividend, 7½ per cent. for the year 1895.

Presentation.—Sir Joseph West Ridgway, Governor-Designate of Ceylon, has been presented with a handsome gift by the directors of the Manx Electric Tramways Company. The presentation took the form of an album of 60 large photographic views of the island.

Sydney (N.S. Wales).—The report of the Government Railway Department notes with satisfaction the addition of a multipolar generator and four motors to the cars on the military road overhead electric line. These enable the motor cars to haul two trailers.

Nuremberg.—The Elektricitäts Atkien-Gesellschaft vormals Schuckert und Co. is about to follow the example of the Helios Company at Cologne and increase its capital. A large extension of the works and the putting down of a quantity of new plant is contemplated.

Westminster Electric Supply Corporation, Limited.—The directors of this Corporation have decided to recommend that a dividend at the rate of 9 per cent. should be paid for the past half year, making, with the interim dividend already paid, a dividend of 7 per cent. for the year.

Liverpool.—The tramway company have been experimenting with mechanical haulage. After rejecting steam and compressed-air locomotives and the cable system, they finally decided against electric traction on the accumulator system, on the ground that it would prove more expensive than horse haulage.

Eastern and South African Telegraph Company, Limited.—This Company announce the payment by warrants on February 1 next of interest for the half-year ended January 31 on its 4 per cent mortgage debentures. The transfer books will be closed from January 28 to February 1, both days inclusive.

Aberdeen.—The Watching and Lighting Committee of the Town Council have decided to erect two overhead electric lamps in Bridge-street, one at the top and the other about 60 yards down. The Docks and Pilotage Committee of the Harbour Board are considering the advisability of lighting the quays by electricity.

Cork.—There have been no objections lodged against the Bill which the Town Council are promoting in Parliament for lighting the city by electricity, but the town clerk has received a letter from the secretary of the Cork Harbour Commissioners asking that some amendments should be made in one of the clauses of the Bill.

Digitized by Google

Eastern Telegraph Company, Limited.—This Company notify that the coupons on its 5 per cent. debentures due February 1 next will be paid, on and after that date, at the banking-house of Messrs. Glyn, Mills, Currie, and Co., 67, Lombard street, E.C. Coupons should be left at the bank three clear days for examination.

New Address—The offices, showrooms, and engineering staff of the Consolidated Telephone Construction and Manufacturing Company, Limited, have been removed from 109, Farringdon-road to 186 and 188, Shaftesbury avenue, W.C., and the works, under the title "Telephone and Electrical Works," are at Coventry.

Bangor.—The Commissioners have agreed that before they decide on the various powers to be sought for in the provisional order they make enquiries in a number of seaside resorts in England, Scotland, and Wales as to the extra powers taken in provisional orders, as they might find something among them which they could also include.

Aberdeen.—The National Telephone Company have brought into requisition at their central office in Market-street a new switchboard, which, while conducing to the comfort of the operators, will also tend to improve the working of the system. The work of fitting up the board has been carried out under the superintendence of Mr. W. Brown, district manager.

A Telephone from London to Berlin.—In the course of the debate upon the Post Office Estimates in the Reichstag, Dr Stephan, Postmaster-General, quoted statistics showing the vast extension which the German postal and telegraphic system had undergone since 1870 and said that it was intended to establish direct telephonic communication between London and Berlin.

Baker-street and Waterloo Railway.—The engineers to the authorised Baker-street and Waterloo Electric Railway have deposited with the Private Bill authorities an estimate of the cost of the proposed extension of the railway to the St. John's Wood terminus of the Sheffield Extension Railway. They estimate that the construction of the further length of line required will be £99,043.

Camberwell, S.E.—The Vestry have decided to offer no objection to the application for a provisional order for electric lighting the district and for the supply of electrical energy by the County of London and Brush Provincial Electric Lighting Company, on condition that separate accounts were kept for Camberwell, and that the Vestry have the power to purchase the undertaking at the end of 21 years.

Taunton.—The Electric Lighting Committee have informed the Council that an application had been made to the Board of Trade for an extension of the time allowed for placing all the mains underground, but they had declined to grant such extension, and said the overhead wire should be removed. The committee had therefore resolved to proceed with the work of laying the cables and removing the wires.

Surbiton.—The District Council have received tenders for lighting the town by electricity from the following: The Capital and Counties Electricity Supply Company, Messrs. Siemens Bros. and Co., the Brush Electric Lighting Company, Messrs. Crompton and Co, Messrs. Sharp and Kent, Messrs Fowler and Co. These tenders will be reported on by Dr. Hopkinson, who has been appointed consulting engineer.

New Company.—The Lancashire and General Tramways and Carriage Company, Limited, was registered on January 17 by J. C. Walker, Dean, and Co, Manchester, with a capital of £10 000 in £5 shares. Object: to obtain rights to run over and work any tram or rail roads in the county of Lancashire. The directors are A. Pilling, H. P. Holt, and E. Bryning. Qualification, £50. Remuneration to be fixed by the Company.

Electricity in Coolgardie.—Mr. Edmund Mitchell, managing director of Scottish Westralia, Limited, who recently went out to Western Australia to arrange with the Government in regard to the introduction of electric power to the fields, has completed the arrangements with the Cabinet whereby they will be enabled to at once proceed with the installation of power works in the colony. The patents of the invention have not yet been completed.

Liverpool Overhead Railway.—The report of this Company for the past half-year ending December 31 states that the accounts show an available balance of £11,499. The directors have resolved to recommend the payment of a dividend of 5 per cent. per annum on the preference and 3½ per cent. per annum on the ordinary shares. For the corresponding period of 1894 the distribution on the ordinary shares was at the rate of 2 per cent. The balance carried forward is £2,074, against £1 087.

City of London Electric Lighting Company.—The revenue return for the quarter ended December 31 last shows gross revenue from sale of current for public lighting £3,107 against £3,181 in the corresponding quarter of last year; from sale of current for private lighting, etc., £40,757 against £26,052; from other sources (estimated), £750, against £404; total, £44,614, against £29 637; increase £14,977. Equivalent of 8-c p. lamps connected on December 31, 1895, 195,317, an increase during the quarter of 24,490.

Cardiff.—The Lighting and Electrical Committee of the Corporation have held an enquiry into the circumstances attending the suspension of certain engineers at the central station, and into the grounds for allegations made by these engineers of inefficient conduct of the electrical machinery. After a protracted sitting the committee adjourned in order that the statements *pro* and *con*, may be specifically submitted in writing to a future meeting. The committee intend to call in an independent expert to overhaul the central lighting station, and to report in due time.

Sell's Telegraphic Directory.—The present year's edition of "Sell's Registered Telegraphic Addresses" contains a very large number of alterations which have been effected since the last annual issue was printed. Upwards of 12,000 new registrations, cancellations, and other alterations have been received from the Post Office, in addition to an enormous number of trades, professions, and telephone numbers included in the alphabetical lists, making together upwards of 30,000 individual alterations. The book is admirably planned, and is invaluable as an authentic guide to the largest business houses of the United Kingdom.

Mile End (London).—Mr. B. H. Jenkinson, consulting electrician to the Mile End Guardians, has submitted plans which provide for driving engines and dynamos together for the lighting of the institutions under the control of the Guardians, and it was recently arranged that Mr. Jenkinson should prepare another plan showing the plant arranged in such a manner as would provide for the same quite separately. Both plans were submitted to the Board, who afterwards gave full power to the Works Committee in regard to the provision of electric light, except the expenditure of money and the entering into contracts involving expenditure of money.

Exeter.—An enquiry has been held by Colonel J. Ord Hasted, R E., Local Government Board inspector, with reference to the application by the City Council for sanction to borrow £11,000 for the purchase of the undertaking of the Exeter Electric Lighting Company, Limited, and for the construction of works of electric lighting. The town clerk (Mr. G. R. Shorto) appeared for the City Council, and Messrs. C. T. K. Roberts and S. Andrew for the electric light company, in support of the application, and Mr. Pitt Lewis, Q.C. (instructed by Mr. Campion), for a number of ratepayers to oppose it. The enquiry occupied two days.

Southport—The borough accountant has submitted the following statement to the Town Council: present borrowing powers, £42,822; expended on account of same—arc lighting, £2,581; private lighting, £39,550—total, £42,131; balance unexpended, £691. It has been resolved that application be made to the Local Government Board for power to borrow a sum of £4 000 for the purpose of providing additional mains, service cables, transformers meters, etc. The borough accountant reported that for the year ending December 31 last the expenditure on revenue account had been £2 324. 14s. 3d, and the income £2,113. 19s 9d., or a loss of £210. 14s. 6d.

Gulcher New Electric Light and Power Company, Limited.—The liquidator having applied to the Court for a declaration that Mr. James Murray was liable to pay calls on 300 shares in the Company, counsel were heard by Mr. Justice Vaughan Williams. The respondent admitted that he agreed to take the shares upon condition that 10s. per share was paid up on a large issue of preference shares. That condition not having been fulfilled, he submitted that he was not bound by the agreement. Mr. Justice Vaughan Williams upheld this contention, and dismissed the summons, with costs, to be paid, not personally by the liquidator, but out of the Company's assets.

Edinburgh.—The Lord Provost's Committee of the Town Council have considered a report by a sub-committee on a letter from the general manager of the National Telephone Company, Limited, in which it was recommended that the proposals made by the company, to the effect that the Corporation should lay down underground tubes for telephone wires at the company's expense, should not be entertained. After consideration and a division, the sub committee's report was approved of. A committee of the Town Council have agreed to recommend that the City Chambers and Royal Exchange-square should be lighted by electricity at an estimated cost of £256.

Merthyr—The Parliamentary Committee of the District Council have reported that Mr. J. C. Howell, the promoter of the provisional order for lighting the town with electricity, agreed to make provision for lighting one mile instead of half that distance. The question of the possible purchase of the undertaking by the Council was then discussed, and ultimately certain terms were mentioned which it was thought could be agreed to, and Mr. Howell was asked to embody these terms in a letter to the Council, and if the terms were agreed to the Council would be prepared to give their consent to the order. It was stated that nothing further had been received in regard to the matter.

Long Eaton—The Harrington Lace Factory is now lighted throughout with electricity, the cost of the work having been about £2,400. Messrs. J. H. Holmes and Co., electric light engineers, Newcastle-on-Tyne, have had the contract, and they are now at work at Whiteley's factory. The plant consists of a 70 h.p. Browett and Lindley engine, fitted with all the latest improvements, including patent expansion governors, driving one of the firm's latest type of Castle dynamos. The special feature of the dynamo is the output of 410 amperes at 115 volts. There is an absolute freedom from sparking, combined with small variation of volts from no load to full load. The installation consists of 950 lamps.

Electric Railways in the City.—The City Church Preservation Society has started an agitation against the removal of the church of St Mary Woolnoth in order to provide a site for a station on the extension of the City and South London Railway. It is stated that in the Bill of 1893, which sanctions the extension of the railway, the name of the church to be removed is not mentioned, although the site is clearly indicated, and the parishioners did not realise until quite recently that the church would be swept away. On the other hand, the company say that the removal of the church was well understood when the plans were passed by the local

Digitized by Google

authorities, and there is practically no other site available. Moreover, the church is not required. The opposition certainly seems somewhat belated, and as the Act has been obtained it is not easy to see that anything serious can come of it.

Copper.—Messrs. James Lewis and Son's mid-monthly report on copper, dated Liverpool, 16th inst., says: "The first price paid for cash good merchantable copper in the new year was £41 7s. 6d. From this level the value gradually fell away to £40. 10s on the 7th, recovering next day to £41. 6s. 3d., declining to £40. 16s. 3d on the 13th, and closing to-day at £41. 5s. 8d. per ton, after £41. 8s. 9d. had been paid. Had it not been for free selling on American account the last few days, prices would have gone still higher. One thousand five hundred and eighty tons of copper have been purchased by the English Admiralty, and there is no doubt that recent political events will lead to a large increase not only of the British but also of foreign navies, for which a considerable quantity of copper will be required The urgent need of additional telegraph cables has also been shown."

Coventry.—In opening the Gas and Trades Exhibition the Mayor (Alderman Loudon) remarked that they had recently been compelled to introduce electric lighting into Coventry. He said "compelled," because if the Corporation had had their choice in the matter they would rather have waited a time to watch the experience of other towns; but they either had to provide electric lighting themselves, or allow some company to step in, which was not desirable Electric lighting would be the light of the future That being so, it was their duty to encourage the use of gas for other purposes than lighting. The experience of other towns had been that the introduction of electricity had made but very little difference to the consumption of gas. The remaining portion of the electric tramway, from the depôt at Foleshill to Bedworth, has been officially inspected on behalf of the Board of Trade. The section already working is between Coventry Station and the depôt.

Nuneaton —Messrs. Willans and Robinson's new engineering works are well on their way towards completion. The foundry at the far end of the block, which was commenced first, is in a particularly forward state, being practically ready to receive its iron roof. The walls of the machine-shop, too, have been run up to a good height. The necessary excavations for the extra wing are being pushed along with every expedition. Mr. H. Weldon, of Birmingham, who is carrying out the earthworks, has between 70 and 80 men, chiefly navvies, busily engaged on the spot, and to facilitate the work a light tramway has been laid down A smithy is to be constructed, covering a space 200ft. long by 150ft. wide. The testing department has been commenced, and at the east end of the building a chimney, 100ft. high, will be built. The foundations have been already laid, and the walls of a tower for the storage of water to supply the large boilers of this department are now several feet above the ground

Saltash —Some time ago Saltash Town Council gave the gas company six months' notice to cease lighting the public lamps, with a view to making fresh terms, and in due time tenders for lighting the town by gas, electricity, or otherwise were invited Only one tender was received, that of Mr. T. Martin, of Plymouth, to supply the electric light, which the Council did not accept. On January 4, when the date arrived for the gas company to cease their supply, nothing had been decided. The gas company then, on its own responsibility, lighted on another 10 days, so that the Council at their next meeting might have another opportunity of considering the matter. The Council then asked the company to continue the light for six months, but the directors unanimously decided to discontinue the lights, with the result that one evening the town was plunged in darkness. The Town Council held a special meeting the next day and decided to accept the gas company's terms to light the town for 12 months, and the public lamps were once more lighted.

Walsall.—The Electric Lighting Committee report that the works for the supply of electricity for lighting and other purposes had been completed, and that the current was supplied from the generating station in Wolverhampton-street to the public on December 14 Since that date the supply had been continued without any intermission or hitch. In order to compensate the customers for the inconvenience caused by the delay in supplying the light, the committee had decided that no charge should be made against them for the first week's supply, a concession which had been much appreciated. The Streets Committee had had under consideration the correspondence between the Electrical Construction Company, Limited, and the South Staffordshire Tramways Company as to the bad state of the tramway lines. A conference had been arranged between the two companies to discuss the points in dispute. The Town Council have decided to place an additional transformer in St. George's Hall sub-station, at a cost of £600, including the necessary cable

Hanley.—The electricity accounts, as presented by the borough surveyor (Mr. Lobley), for the year ending December 31 show that the revenue amounted to £3,724. 3s. 8d., and the expenditure to £3,623 17s. 1d., showing a balance on the right side of £100 6s. 5d. The actual working expenses amounted to only £2,286. The total sum expended is made up by two important items—viz, £754. 8s. 10d. for interest, and £587. 18s. 10d. to account of principal repaid. The total amount of loans sanctioned by the Board of Trade for electricity works is £46,110. At the close of 1894 the amount borrowed (at 3 per cent.) was £21,645. At the end of December last this amount had been increased to £32,363, and this capital has been expended. A margin of £13,747 remains available for further extensions. The principal items of revenue were: electricity supply, £3,444; meter rents, £75. The profit before setting aside depreciation was £1 443. The statutory price of electricity is 8d. per unit. The price charged last year was 6d. per unit with 5 per cent. discount on prompt payment. The average price obtained is stated at 4·58d The number of units sold last year was 180 000. Preparations are being rapidly pushed forward for lighting Shelton parish church by electricity.

London Lighting Extensions.—Notices under the Electric Lighting Acts and Orders have been given to the London County Council by the Charing Cross and Strand Electricity Supply Corporation to lay mains in Spring-gardens The St. Pancras Vestry have given notice to lay mains in Fortess-road. The Vestry of Hampstead propose to lay mains in Frognal, West End-lane, Oakhill-park, Willoughby-road (east side), Fellows-road (north side), Primrose Hill-road, King's College-road, Dennington-park-road, Greencroft-gardens (north side). A notice, dated December 24, 1895, has been given by the London Electric Supply Corporation, of intention to lay distributing mains, consisting of lead-covered cables in cast-iron pipes, in Duke-street, Grosvenor-square. The County of London and Brush Provincial Electric Lighting Company intend to construct a transformer-box of large size at Windsor-terrace, City-road. The St. James and Pall Mall Electric Light Company have given a notice, dated January 3, of intention to lay mains in Pall Mall-place, and across Pall-mall in two places. A further notice, dated January 3, from the Vestry of St. Pancras was to lay mains across Euston-road. The County Council Committee reported that there was no objection to the notices.

Appointments Vacant.—The Plymouth Corporation invite applications for the office of electrical engineer. Applicants must have had previous experience as electrical engineer to some corporation or company supplying electricity under parliamentary powers, and must be competent to design and to supervise the construction of the generating station, plant, machinery, appliances, and cables necessary to generate and supply electricity for public and private lighting and for power and tramcar traction purposes in a town with a population of 90,000 persons. The gentleman appointed will be required to undertake the management and control under the instructions of the Electricity Committee of the electricity undertaking authorised by the provisional order obtained by the Corporation of Plymouth, and will be required to devote the whole of his time to their service. Salary, £300 per annum, rising by four equal annual increments to £400 per annum. It is desirable that applicants should not be more than 40 nor less than 30 years of age. Canvassing by or on behalf of candidates will operate as a disqualification. Applications, accompanied by copies of not more than four recent testimonials as to character and qualifications, endorsed "Electrical Engineer," must reach Mr. J. H. Ellis, town clerk, Municipal Buildings, Plymouth, by February 14.

Waterloo and City Railway.—The accounts for the half-year ending December 31, 1895, show a capital expenditure during that period of £62,321, making the total outlay £122,736. The works have continued to make good progress. An agreement has been settled with the South-Western Railway Company for the easements required from them for the terminus at Waterloo. Arrangements have also been made with the Central London Railway Company with respect to the City terminus. The engineer reports that during the past six months the works have made steady progress on both sides of the Thames. Towards the City both tunnels are in the London clay beneath the low-level sewer, the Metropolitan District Railway, and Queen Victoria-street, and have reached a point about midway between Benet's-hill and Lambeth-hill, near the College of Arms Towards Waterloo the tunnels have for some time past been driven under compressed air under Stamford-street, and are, on the average, about 150 yards eastward of the junction of the Waterloo Bridge-road with Stamford-street. The total length of single tunnel excavated during the past six months has been 1 635 yards, the total length of single tunnel completed is now 2 835 yards, leaving a total length of single tunnel to be constructed between the terminal stations at either end of the railway of 1,656 yards.

Glasgow.—At a meeting of the Town Council Mr. Guthrie called attention to the fact that the collection of electric lighting rents at this date was £5,389. 8s. 5d, an increase of only £167. 10s. on the previous year, while the collection of gas rents was £125,274. 4s., an increase of £2,149 4s 11d. on the previous year. With reference to the electric light, that statement, he thought, was most discouraging. He knew that many tenants throughout the city were abandoning the electric light, and he impressed upon the convener to lose no time in visiting many towns to secure such information as would make the electric lighting of Glasgow what it should be—a success. Bailie Burt, convener of the committee, deprecated the statements as to the non success of the electric light in Glasgow. He did not think it was fair to run down the system and make comparisons without thoroughly understanding the position. He had no hesitation in saying that the electric lighting of Glasgow had been an unqualified success. They had extended their station, and although they had had difficulties to contend with which added very much to the cost of their street-lighting system, their revenue had been increasing steadily. The matter then dropped. The Tramway Sub-Committee have met to consider the lighting of the tramway cars, but further consideration was postponed in order that Mr. Young, the manager, might have an interview with the company which had originally undertaken to light the cars with electricity.

London County Council.—The Fire Brigade Committee report as follows on the question of establishing electric communication with fire stations: "With a view to reducing the number of false alarms communicated to the brigade from business and other

Digitized by Google

establishments in electric communication with fire-engine stations, it was some years ago determined that in future persons who wished to have the privilege of having such communication should not be allowed to use call-bells, but that the communication should be telephonic. The chief officer informs us that there has recently been submitted to him a new form of fire-alarm by means of which an accidental ringing of the bell from contact of wires or other causes can at once be distinguished in a fire station from a proper call, and on his recommendation we have revoked the order prohibiting the introduction of call bells. The chief officer is of opinion that every effort should be made to encourage persons to place their premises in electric communication with fire stations, and with that view he suggests that the annual charge of £5 now made for the privilege should be substantially reduced. Having carefully considered the matter, we have decided to reduce the charge to £2. 2s. a year, and now report our action in order that attention may be directed to the advantage to manufacturers and others of having their premises in direct communication with fire stations, instead of relying in the fire-alarms fixed on the public thoroughfares." Mr. Emden moved, in pursuance of notice: "That it be referred to the Highways Committee to consider and report without delay on the expediency of the Council and the local authorities to construct subways under the streets of London for the reception of the tube and wires of the gas, water, electric, and other companies, and to charge rents for the same." Major Probyn seconded the resolution, which was agreed to, with the addition of a similar reference to the Parliamentary Committee.

Eccles.—We have received a copy of the pamphlet which the Council have issued to the ratepayers giving information on electric lighting, with the committee's reasons for recommending the establishment of works. The pamphlet first gives a history of the movement in the borough, and then goes on to state that 110 local authorities in England and Wales had taken up the question, and in about 40 places the works were already in operation and in no case had a corporation expressed the opinion that they had done wrong. A Local Government Board inspector had told them that the Board were constantly holding enquiries into applications for borrowing powers for extensions of schemes, and he had not met a single instance in which the works had not been a financial success. Testimony such as that was of immense value and reliable beyond any mere casual talk of irresponsible people, and such as ought to satisfy any reasonable man that there was no need for further delay with its attendant risks of the town losing the advantages they had obtained of power to become their own providers of electric light. Comparing their conditions with other boroughs, they were far and away more favourable. Many other towns had gasworks in their own hands and had to compete against themselves; but in Eccles they had no gasworks, and they had a settled certain steady customer in themselves for a revenue of over £1,600 a year, or the equivalent of 3,200 lights at 10s. per light per annum. They had already spent about £1,000, which was a certain loss if they abandoned the scheme. The scheme would provide for lighting the whole of the street lamps in the borough, and for appropriating as revenue to the electric works the actual sum which was at present paid to Salford for street-lighting. They had provided for 1,800 lights, but if that number should not be required the committee would delay spending the full sum until the demand is received. The immediate capital outlay would be £16,471, and the annual charges, including works, maintenance, interest, and sinking fund would be £1,738. They at present paid Salford for gas-lighting £1,665 per annum. If the works were not carried out the provisional order would lapse in June next; the cost of obtaining that order and the previous one (over £1,000) would be thrown away; the £1,000 would have to be paid off by a rate raised immediately (about 2½d. in the £) whereas if the works went on it could be spread over 30 years; and a company would get power to break up their streets as and when they required to lay mains, services, etc., and would practically acquire the exclusive right to supply what was likely to become one of the necessities of the future for illuminating purposes. If the works were carried out the Corporation would establish works under their powers, and acquire for the first time the control of their street-lighting, with the advantage of being able hereafter to improve it at proportionately small expense. The Corporation would be able to run the works and manage them in the interests of the community, studying the advantage of both consumers and ratepayers; the ratepayers would acquire at the end of 30 years, at no cost to the rates in the meantime, a valuable property and business, and there would be no need to lay a rate to wipe out the preliminary charges, as the amount could be borrowed and repaid gradually. Without making any allowance for economy in consumption, or the other economies attendant upon the use of the electric light, it had been demonstrated in several parts of the country that electric light at 6d. per unit equalled gas at 3s. per 1,000 cubic feet; 5d. per unit equalled 2s. 6d. for gas; and 4d. per unit equalled 2s. for gas. The pamphlet, which dealt with the subject most fully, was signed by the members of the Electric Lighting Committee.

Colchester.—The Town Council have thoroughly discussed the electric lighting question, and have now decided to undertake the work and erect the necessary plant and machinery. At the meeting held on January 1 the Council in committee presented a report, in which they stated that they had adopted a special report presented by the Lighting Committee which had been to the effect that an important communication having been received from the officer commanding the Royal Engineers in the Eastern District in reference to the lighting of certain military premises, the Lighting Committee, in view of the letter from the War Department, and that a reply was evidently urgently required, recommended that the provisional order be put into operation, and that they be directed to arrange terms with Mr. Massey, or other technical expert, to prepare a scheme, with specification and plans, on which tenders could be invited from firms of electrical engineers of good standing; to enter into provisional agreements with owners of suitable land on which works might be erected, and obtain plans, specifications, and tenders for the requisite buildings; to prepare particulars for the Local Government Board with a view to application being made for their sanction to the borrowing of the sum required; and to make provisional arrangements with the War Department for the supply of electric light. An additional report stated that Mr. Arthur T. Osborne was willing to sell a piece of land, with stable, adjoining the Stanwell-street depôt for £500, and a piece of land in Stanwell street for £400. A letter from the C R E, stating that the War Office will be prepared to take a supply of electricity for the hospital, was included in the report. Major Skinner, R.E., in reply to a deputation from the committee, stated that the War Department would be prepared to enter into a contract with the Council for the supply of electric light to about 500 lamps at the new military hospital, the price to be charged for the current supplied to be 6d. per Board of Trade unit, the Council to bear the expense of laying the main to a point outside the gates of the hospital, and the supply to be furnished by not later than May next. The committee were of opinion that 6d. per unit was a fair price, and recommended the Council to accept the offer. The committee suggested that a communication be made to the War Department asking that, in the event of the electric light being established, the Council be allowed to supply light in the new infantry barracks, which will probably require about 750 lamps. As to the cost of the work, Mr. W. H. Massey wrote as follows: "If you refer to my report of May 4, 1894, you will see that about £13,000 is put down for street-lighting and private house lighting to the extent of 4,000 or 5,000 lamps fixed; and I don't believe you can do the thing in a creditable way for less, especially at the present time, when the prices of electrical manufactures are a little higher than they were 18 months ago. But if you give up the street arc lighting, which I never recommended in the early stages of central-station working (and which I only included in the estimates at the request of your committee), the difficulty I alluded to in regard to making the electric light pay its way from the beginning, even in the hands of a corporation able to raise capital on easier terms than a company, would be almost entirely removed; and the provision made in the estimated first outlay for arc light apparatus ought to be more than sufficient to cover the cost of mains, etc., for the hospital and barracks, so that a total of £13,000 will most probably enable you to do all that is required (including buildings, etc.,) to begin with. If you secure this extra lighting, there is little doubt but that you would soon be obliged to extend your works to meet the demands in the town itself, and it would, of course, be more profitable to work a £20,000 scheme than a smaller one of £13,000; but in no case would I go in for street-lighting except out of profits. The plans I prepared and sent to Mr. E. Thompson Smith last July will show exactly what can be done as to building a small station, which could be cheaply added to at any time. The remainder of the report consisted of extracts from replies received from boroughs using electricity." The Council, at a special meeting, adopted these two reports, and decided to invite schemes with plans and specifications from four firms of good standing, and to arrange terms with Mr. Massey to advise them upon such plans.

PROVISIONAL PATENTS, 1896.

JANUARY 9.

604. Improvements in insulated anchoring apparatus for use on underground or overhead conductors of electricity. Sydney William Baynes, 33, Haverstock-hill, London.

JANUARY 10.

699. Improvements in electric arc lamps. Harry Neville Moody, 28, Southampton-buildings, Chancery-lane, London.

701. Improvements in electric signalling apparatus. Belisairo Marinovitch, 28, Southampton buildings, Chancery-lane, London.

710. Improvements in and relating to electric accumulators. Audley Charles Miles and Bernhard Fietz de Morgenstern, 151, Strand, London.

711. Improvements in and relating to arc lamps. Audley Charles Miles and Bernhard Fietz de Morgenstern, 151, Strand, London.

712. Improvements in and relating to electric motors. Audley Charles Miles and Bernhard Fietz de Morgenstern, 151, Strand, London.

719. Improvements in electrical accumulators or storage batteries. Benjamin Willcox, 47, Lincoln's-inn-fields, London. (La Société l'Accumulateur Fulmen, France.)

722. Improvements in electric arc lamps. John Isaac Thornycroft and John Edward Thornycroft, 46, Lincoln's-inn-fields, London.

JANUARY 11.

736. Improvements in electric tramways or railways. William Burgess Edgar, 154, St. Vincent-street, Glasgow.

778. Improvements in secondary batteries. Henry William Headland, 77, Chancery-lane, London.

Digitized by Google

780. **A new or improved method of manufacturing electrodes for secondary electric batteries.** Henry Leitner, 1, Broad street-buildings, Liverpool-street, London. (Complete specification.)

791. **Improvements in primary voltaic batteries.** William Walker, jun., Frank Richard Wilkins, Jabez Lones, and Charles Vernon 7, Staple inn, London

793. **A new or improved electrical lamp.** Herbert John Dowsing and Henry Sheehy Keating, 28, Southampton-buildings, Chancery-lane, London.

794. **A new or improved electrical lamp.** Herbert John Dowsing and Henry Sheehy Keating, 28, Southampton-buildings, Chancery-lane, London.

810. **Improvements in apparatus for automatically controlling the supply of electricity and gas, water, or other fluids.** Guy Carey Fricker, 46 Lincoln's inn-fields, London.

JANUARY 13.

842. **Improvements in and connected with the manufacture of electric conductors.** Sherard Osborn Cowper-Coles, 16 Adam-street, Manchester-square, London.

845. **Improvements in electrical appliances for automatically preventing railway collisions.** Dominik Weisz and Emil Epstein, 8 Quality-court, Chancery-lane, London. (Complete specification)

868. **Improvements in electric meters.** Carl Raab, 31, High Holborn, London.

879. **Improvements in electric measuring instruments.** Evershed and Vignoles, Limited, and Sydney Evershed, 1 Woodfield-road, Harrow road, London.

880. **Improvements in electric heaters.** George Ewart and John Vaughan-Sherrin, 77, Chancery-lane, London. (Complete specification)

888. **An improved secondary battery or accumulator.** Alfred Upton Alcock, 46, Lincoln's-inn-fields, London

JANUARY 14.

915. **Improvements in electric transformers for alternating currents.** Ernest Scott, The Elms, Bushbury-lane, Wolverhampton.

916. **Safety non-sparking switch.** Ernest Scott and E James Cochrane, The Elms, Bushbury-lane, Wolverhampton.

931. **Improvements in and relating to electrical devices for igniting gas.** James Kerr Semple, 263, Argyle street, Glasgow.

964. **Improvements in telephonic apparatus.** Carl Joseph Schwarze. 45 Southampton-buildings, Chancery-lane, London (Complete specification.)

976. **Improvements in or relating to electric arc lamps.** Henry James Fisher, 70, Chancery-lane, London.

977. **Improvements relating to the synchronising of alternating-current motors for electrical power transmission.** Horace Field Parshall 70, Chancery-lane, London. (Complete specification)

986. **Improvements in the electro-deposition of metals.** John Cameron Graham, 18, Southampton-buildings, Chancery-lane, London.

JANUARY 15.

1006. **Improvements in electrical resistances.** Maximilian Zinner, jun., 4 Corporation-street, Manchester. (Complete specification.)

1037. **Improvements in apparatus for rope railways, "telpherage" lines, tramways, traction, haulage, driving, and like purposes.** Cornelius Edward Kelway, 21 Walbrook, London.

1054. **Improvements in voltaic batteries.** Desmond Gerald Fitz Gerald and Walter Charles Bersey, 53, Chancery-lane, London.

1068. **An improved electrical process for recovering metals from weak solutions and for concentrating the electrolyte.** John Cameron Graham, 18, Southampton-buildings, Chancery lane London.

1069. **Improvements in or connected with electrical condensers.** Charles Pollak, 47, Lincoln's-inn fields, London.

JANUARY 16.

1123. **Improvement of "iron-clad" field magnets.** Thomas Pilkinton, 15, Maryon-road, Charlton, London.

1144. **Improvements in electrodes for electrolytical purposes.** Wilhelm Heraeus, 45, Southampton-buildings, Chancery-lane, London.

JANUARY 17.

1198. **Improvements in electric railways.** John Wesley Darley, jun. 31, Southampton buildings, Chancery-lane, London. (Complete specification.)

1218. **Improvements relating to electric railways.** George Tolmie, 55 Chancery-lane, London.

1230. **Improvements in apparatus for measuring electricity.** Edward Howard Percy Humphreys, 55, Chancery-lane, London.

1237. **Improvements in and relating to electric incandescent lamps.** Charles John Peach Robertson, 6, Bream's-buildings, Chancery-lane, London.

1249. **Improvements in synchronising mechanisms for alternating-current generators.** Horace Field Parshall, 70, Chancery-lane, London.

1238. **Improvements in the manufacture of electric batteries.** Philip Arthur Newton, 6, Bream's-buildings, Chancery-lane, London. (Charles Willms, United States.) (Complete specification)

1256. **Improvements in electric choking or impedance coils.** William James Davy, 40, Chancery-lane, London.

JANUARY 18

1310. **Improvements in electrical igniting apparatus.** Hugo Hirst and Arthur Ernest Angold, 88, Queen Victoria-street, London.

NOTES.

Appointment.—Major George A. Carr, R.E., has been selected for appointment as an instructor in electricity at the School of Military Engineering, Chatham, vice Major A. H. Bagnold, whose tenure of the post expires.

Football by Electric Light.—Thames Ironworks have again been playing football by electric light, and this time the affair proved a great success. The Ironworks beat their opponents, Barking Woodville, by six goals to two.

Institution of Civil Engineers.—A special general meeting has been called for February 6 in order to consider propositions for increasing the number of the council, and allowing proxy voting in the election of the council and officers. A supplemental charter will be required to effect the alterations.

Telegraphic Congress.—According to *L'Elettricità*, the Italian Minister of Posts and Telegraphs has submitted several proposals to the Organising Committee of the International Postal and Telegraphic Congress to take place this year at Budapest. The proposals will be in the direction of a reduction of the international tariffs, and possibly of a single rate for the whole of Europe.

South African Cables Again.—The Postal Telegraph authorities announced on Tuesday that the St. Thomas and Loanda cable had been repaired, but that the Aden-Zanzibar cable was again interrupted, so that all telegrams for the South and East Coast of Africa had to be sent by the West Coast route. At the present time these repeated breakdowns are most unfortunate.

Quick-Acting Thermometer.—It is stated in *Wiedemann's Annalen* that the difficulty of obtaining instruments to indicate rapid variations of temperature has induced Herr Paul Czermak, of Graz, to try thermo-elements with very fine wires for meteorological observations. These are found to be superior to thermometers with platinum bulbs, and much better than glass-bulb thermometers, where rapid changes of temperature are to be measured.

Central Supplies.—Dr. Martin Kallman, the Berlin city electrical engineer, has been writing in the *Elektrotechnischer Anzeiger* on the subject of common generating stations as centres for electric lighting, power, and tramway work. In this direction he thinks that there is a great future for electricity, and that the centralisation of the supply of electric energy for all purposes will be an important factor in municipal progress.

Pocket Catalogue.—We have received from the Electrical Power Storage Company, Limited, a copy of their neat little "Pocket Catalogue" for 1896. Its contents comprises a quantity of useful information relative to the company's well-known type of storage cells, besides information *re* their various other manufactures, and several useful tables, etc. The reverse side of each page is squared paper, which feature will render this little catalogue of special value to electrical engineers.

Motor Carriages.—In Scotland the local magistrates do not appear so certain as in England that every self-propelled vehicle is for the purposes of the Highways and Locomotives Act a traction engine, for on Mr. George Johnston being charged at Glasgow with using a horseless carriage in Buchanan-street, the presiding magistrate has taken till to-day (Friday) to consider the matter. The chief point taken by the defendant was the issue of the Excise license, which authorised him to run a carriage propelled by not more than two horses or mules, or by mechanical power. No Excise license was required for a locomotive.

Storage Batteries.—Herr F. Grünwald, writing in the *Elektrotechniker Anzeiger* of January 26 on the subject of the Faure patent, which expires in Germany on February 8, reviews the various steps which led to the discovery of the storage battery, the various forms now produced, and the possibility of their improvement. The conclusion of the article is that the expiration of the patent throws open a wide field for experiment and research. Whether any important results will be obtained cannot be predicted, but it may happen so when the disturbing influence of the monopoly is removed.

A Slight Discrepancy.—The following is taken from the New York *Electrical Engineer*: "The police reports for December to the Board of Administration of Cincinnati were filed a few days ago. The police reported 9,690 hours and 18 minutes' outages, and the Edison Company but 5,241 hours and 20 minutes' outages, a difference of 4,448 hours and 58 minutes. This involves a deduction of 97·88dol. from the Edison Company's bill. The Board decided hereafter to accept the police report as correct and final. There may be litigation on the matter, but the Board feels the position it has taken is demanded by regard for the public interests, and will maintain it."

Proposed Cable to Hawaii.—According to the terms of the Bill introduced by Senator Hale in the United States Senate, the United States Postmaster-General will contract with the Pacific Cable Company for the construction of a telegraph cable between San Francisco and Honolulu, Hawaii. The United States is to pay the company annually a sum equal to 4 per cent. of the amount expended each year by the company. The contract is to continue for 20 years, and the line is to be completed by July 1, 1897. It is also provided that the Government may come into the ownership of the proposed line by paying the cost price for it with 5 per cent. added.

Electric Furnace for Bar Iron.—According to the *Canadian Electrical News*, the Montreal Electric Company have recently put up an electric furnace at the works of Messrs. Peck, Barry, and Co. for heating bar iron intended to be converted into horsenails. The current, at a potential of 1,040 volts, is taken from the mains of the lighting company and is reduced to 20 volts by a Siemens transformer. The furnace itself consists of a carbon tube 2ft. 6in. long and 2in. in diameter. The bar of iron is slid through the tube, which is covered with sand. On a current being passed through the carbon, the iron is rapidly heated, 5ft. of the bar being brought to the proper temperature per minute.

Volta Centenary.—The *Provincia di Como* says that the idea of celebrating the centenary of the invention of the voltaic pile by an electrical exhibition to be held in Como in honour of Alessandro Volta in 1899 has found warm supporters, and there appears every reason to hope that the project will be carried out. When this year's expenditure is discussed by the Municipal Council, it will be proposed to set aside a fixed sum for three years, with the view of forming a nucleus for the exhibition fund, which will be augmented by private subscriptions. It is understood that Prof. Colombo, Signor Ferraris, of Turin, and a number of eminent scientific men are willing to serve on the exhibition committee, and it is also considered that the occasion would be a suitable one for a grand congress of electricians.

Calcium Carbide.—Mr. O. E. Dunlap, writing in the New York *Electrical Engineer*, says that it is expected that before the month ends calcium carbide will be made in the new plant at Niagara Falls. The product of this initial plant will be sent to Philadelphia in barrels and there

Digitized by Google

manufactured into acetylene gas to supply Southern Pennsylvania. The new plant here being the first of its kind, many interesting experiments will be made in it. At the starting of operations it will be important to ascertain the amount of electric current which will prove the most economical, for so far the experiments have been made with current varying from 25 h.p. to 235 h.p. The contract of the company with the Niagara Falls Power Company calls for 1,000 or more horse-power. The current is received at 2,200 volts, and used at a voltage of about 100. It is considered probable that calcium carbide will be manufactured at a cost not to exceed 5dol. per ton.

An Unexpected Danger.—Mr. J. B. Foote, writing in the New York *Electrical World* on the subject of generating stations, relates how on one occasion he got into trouble with a static discharge. An alternator and two arc dynamos were being driven by belts from a maple-wood driving-wheel worked by a turbine. "The belts running over the wood driving pulley had no chance to discharge themselves of the static current which they generated, as they were entirely insulated from the ground, but gave no serious trouble until this fall with a very dry atmosphere, the alternator became so charged that the current jumped from the field poles to the armature conductors, making two punctures on exactly opposite sides of the armature. The dynamo current following the static discharge made some brilliant fireworks for a few seconds; the men in charge shut down and put in a new armature, which was no sooner started than the same experience was repeated."

Chemical Society.—At the memorial lecture on the life and work of the late Prof. von Helmholtz, delivered before the Chemical Society by Prof. G. F. Fitzgerald, F.R.S., there was a large audience, including Sir Joseph Lister, Lord Rayleigh, Sir Henry Roscoe, Prof. Armstrong, Dr. Frankland, Prof. Ramsay, and Prof. Roberts-Austen. The lecture dealt mainly with questions of the physical constitution of matter, viewed in relation to theories enunciated by Helmholtz. The lecturer mentioned that the children of his intellect valued most by Helmholtz were his mathematical theories of fluid and vortex motion, and went on to show some of the difficulties inherent in Lord Kelvin's suggestion, based on Helmholtz's theories, that atoms are vortices in a perfect fluid. Passing to the discussion of some of the problems of capillarity, solution, and electrolysis, he concluded by saying that Helmholtz had brought us measurably nearer to an ultimate dynamical explanation of the universe.

Measuring Frequency.—A method of measuring the frequency of an alternating current has been described in the *Zeitschrift für Elektrotechnik* by means of a Mariotte bottle filled with water. The bottle is placed on an iron support about one metre high, and the lower horizontal opening has a diameter of 2mm.; a horseshoe electromagnet, through which the alternating current is passed, is placed near to this iron support, which forms its armature and is therefore set into vibration; for each oscillation a drop of water from the bottle is thrown off, and the stream of water will therefore be separated into a regular series of drops, the number of which per second is equal to double the frequency. If this stream is examined through a stroboscopic disc, it is easy to adjust its speed so that the drops appear to remain stationary. The speed is then measured with a speed counter or by means of a chronographic arrangement. The results of some observations are given, and they are said to be correct within one-sixth per cent.

Electric Towage.—In reference to the bestowal of the Montyon premium upon M. Galliot, of Dijon, for the system of electric towage established by him in one of the sections of the Burgundy Canal, the *Revue Industrielle* remarks that it was not on its electrical side that M. Galliot's work was especially remarkable, since the arrangement adopted was very similar to those already used in overhead tramway work. What, however, took the attention of the commission of awards was that for the first time the power required for traction was obtained from the two weirs at the ends of the section. In reference to this, it may be remarked that, in general, the water supply of a canal is very limited—in fact, only just enough to fill the locks, but in the case of a canalised river where a large amount of water goes over the weirs something of the sort is at least possible, though it might be difficult to work out economically. In the case of the particular section of the Burgundy Canal dealt with by M. Galliot the traffic is not very heavy, and there is a fair amount of water available.

The Hampstead Accident.—The evidence taken by Dr. Danford Thomas at the inquest on the death of Edwin Clarkson at the Hampstead Vestry's central electric lighting station last week, has not brought out very conclusively how the accident came about. Mr. Frederick W. Schiller, an engineer employed by Messrs. Siemens Bros., said that the deceased had made a disconnection when the accident occurred. It was not work in which gloves should be worn, and he could not explain how the accident happened. Mr. G. H. Cottam, the Vestry's electrical engineer, said the current was not on the wire which Clarkson had to disconnect, but it was on an adjacent one, and whilst doing the work he probably handled that wire, at the same time touching an adjoining terminal with the elbow of his other arm. In that way he could have received the shock which caused his death. The jury returned a verdict of accidental death, and suggested that the workmen should be compelled to wear gloves when engaged in any dangerous electrical work. It does not appear that any reference was made to protecting the bare arm. The Vestry was represented by Mr. A. P. Johnson, vestry clerk, and several members were present. Mr. A. J. Cameron, of the Home Office, her Majesty's inspector of factories, also attended.

Manufacture of Light.—A summary is given by *Industries and Iron* of a lecture delivered before the Royal Society of Canada in which Prof. John Cox presented in a very striking way what he terms some unsolved problems in the manufacture of light. He pointed out that in practice not more than from 7 to 16 per cent. of the energy of the fuel used can be realised through the engine, whilst theoretical considerations establish a limit at about 30 per cent., beyond which it would seem to be hopeless to expect to pass in any form of heat engine. He referred to the remarkable efficiency of the dynamo, which is so perfect that scarcely any heat is lost in the current conversion. This represented, in contradistinction to the conversion of coal into energy, the second stage in light manufacture. In the third, that of the incandescent lamp, where it was stated only 7 per cent. of the original energy was available, he remarked that the only means thus far used for producing luminous energy was to heat the molecules of some substance, and in this operation we are compelled to waste the greater portion of our available energy in producing heat before we obtain the light rays. Prof. Cox maintains that even in the arc lamp only from 3 to 5 per cent. of the energy supplied is converted into light, and that, therefore, of the original store of coal less than three parts in a thousand become ultimately useful. If, he said, electrical oscillations could be produced with sufficient rapidity, the molecules of matter might be discarded, and light manufactured without their intervention.

City and Guilds Institute.—In presenting the prizes to the successful students of the City and Guilds of London Institute for the Advancement of Technical Education, at the Merchant Taylors' Hall, Sir E. Clarke, Q.C., M.P., remarked that an immense deal of money was being wasted in the country on what was called technical education. It was a great misfortune that, through a parliamentary accident a few years ago, sums of money were put at the disposal of bodies who had no experience or knowledge of how they should be expended on technical education. Whatever mistakes might have been made elsewhere in bestowing scholarships on students simply because they had done pretty well in the earlier schools, without regard to their future life or surroundings, the guilds of the City of London had proceeded on the sound advice that they should not attempt to deal with mere manual dexterity or the ordinary sort of capacity. The more the introduction of mechanical, electrical, and chemical science tended to reduce the work of the ordinary labourer to the mere monotonous performance of one simple mechanical act, the more important it was that there should be the highest skill in the direction and management of that labour, and that was the work to which the guilds of the City of London, with a true instinct as to the future, set their minds more than 20 years ago. He hoped that they would never allow their establishment to come under the control, or even much under the influence, of the Government Department. The guilds of London were quite rich enough to maintain that institute for all time as an establishment where the best teaching that science could offer and money could command would be ready for the equipment of the students.

Lighting Railway Trains.—The *Engineering Review* has a long article on this subject. It is remarked that "there is no feature of railway travelling that involves greater comfort or greater discomfort, as the case may be, to the average traveller, than that of a well-lit or a badly-lit train. So much is this the case, that, other things being equal, it may be safe to say that the average passenger will generally prefer to travel by the route that has the best lighted equipment." This is perfectly true, but the trouble is that the railway companies do not seem to be able to realise the fact. Our contemporary, however, adds: "Many different systems of train-lighting are still competing for public favour, but while the oil lamp and the gas jet have had most of the running in the past, it looks as if electricity and the Pintsch, or some other similar system, was to hold the field in the future." Much more progress in this respect has been made in America than in this country, a result that may possibly be due to the very long journeys undertaken there. A dim light such as is supplied by some of the English lines may be put up with for a short run, but something much better is wanted when long periods of time have to be spent in the train. In the United States many different systems of electric train-lighting have been tried, every possible combination of separate or axle-driven dynamo and storage battery having been experimented with, but the use of electric lighting has not extended in the manner that might be expected in view of the fact that the experience of the Chesapeake and Ohio Railway shows that electric lighting (Silvey system) works out 13 per cent. cheaper than Pintsch gas, which is the only formidable competitor from the point of view of a satisfactory light which shall be at the same time reasonably safe.

Gas-Engines.—A paper has been read before the Institution of Civil Engineers by Mr. Dugald Clerk on the subject of gas-engines. Mr. Clerk said that the theory of the gas-engine outlined in a paper read by him before the institution in 1882 was now generally accepted, while the stratification theory had vanished. Great advances had since been made in gas-engine construction, and the heat-efficiency of such engines had been much improved, while the dimensions and power had increased. Engines working on the Otto cycle had been proved to be the best adapted of all yet invented for present needs, and their popularity had gradually led to the extinction of other types. From a mechanical point of view the Otto cycle was a very imperfect one, allowing at most an impulse for every two revolutions of the crankshaft for each single-acting power cylinder, but the mechanical imperfections of the engine had until now been more than compensated by the simplicity of the single cylinder and piston, and the readiness with which the practical conditions of charging, exploding, expanding, and exhausting could be made to comply with the requirements of economical working. The great difficulty of the problems involved in impulse-every-revolution gas-engines was then referred to, and the author described several engines which had been designed with a view to overcome these difficulties. Experiment and theory showed that the efficiency of a gas-engine increased with the dimensions up to a limit which could be calculated. Further economy might be obtained by increasing the compression and expansion, but it was considered that for high compressions and large gas-engines it would be advisable to adopt the compound principle, although the conditions of success, for compound gas-engines, were not yet fully understood.

Electric Power Distribution.—The Chicago *Electrical Journal* gives a report of a paper read by Mr. L. B. Stillwell before the Engineers' Society of Western Pennsylvania at Pittsburg on December 19, on the substitution of electric for steam power, and the consequent abatement of the nuisance which has earned for Pittsburg the pseudonym of the "smoky city." From a series of calculations Mr. Stillwell deduced that in the central wards of Pittsburg and Allegheny a marked saving for the users of power would result, in the case of all but very large steam plants, from the substitution of electric motors supplied with energy from a 20,000-h.p. central station. He suggested two plans, one a central station located 10 miles from the court house and one installed in the city, preferably on the banks of the Monongahela near the coal supply. He considered the second plan the better. To instal a 20,000-h.p. electric plant in the city would cost, Mr. Stillwell estimated, 3,000,000dol., and the total annual charges, including operating expenses, maintenance, taxes, insurance, and interest on investment, would not exceed 600,000dol. Such a plant would be capable of delivering to the premises of the users of power 17,000 h.p. Allowing 3 per cent. for losses in the transformers and 15 per cent. for average losses in the motors installed by the users of power, the plant could deliver at the shafts of these motors 14,000 h.p. at any given time. As all the customers would not always be using the maximum of power which their motors could develop, it should be possible to supply from such a plant motors aggregating not less than 20,000 h.p. Allowing annual dividends of 10 per cent. on the 3,000,000dol investment to be added to the annual charges, making a total of 900,000dol. per annum, the cost per horse-power, calculating that the plant would supply 20,000 h.p., would be 45dol. a year. This figure, Mr. Stillwell said, is considerably under the average cost in Pittsburg, excluding from consideration plants using more than 2,000 h.p.

Fire Risk Rules.—We have already noticed the changes in the rules of the American Underwriters' National Electric Association, but the following four resolutions adopted by the special committee of the association will be new to our readers. They were: "(1)

Digitized by Google

That any increase of voltage on interior incandescent lighting circuits would result in a corresponding increase of danger to life and property, and that owing to the tendency toward the introduction of high voltages, it be urged that extreme care be taken by inspectors and others in charge of such installations, without which we believe serious hazards may be incurred; (2) that the members of this committee, and other electrical inspectors here present, pledge ourselves to exert our influence to further the enforcement of the rules and requirements of the National Board of Fire Underwriters, and to co-operate with the Electrical Bureau of said Board in furnishing that bureau with facts that come under our observation regarding devices and materials which may not be constructed in accordance with these rules and the introduction of which would create a hazard to property; (3) that we further agree that all bureau reports received setting forth such facts shall receive careful consideration, and the findings of the report be followed out as far as possible in our respective territories, to the end that co-operative work along these lines may be established and uniformity of action in all essential matters secured; (4) that the introduction of trolley wires in municipal districts is inimical to the safety of the property of the inhabitants of such districts, and that because of this fact all possible precautions should be taken by the managers of trolley roads throughout the country to insure cutting the current off the wires in case of fire in abutting property; also, that trolley wires should be effectually protected against the possibility of contact between them and other conductors; also, that trolley systems should be so arranged that practically no difference of potential due to the effects of trolley roads should exist between subterranean pipes."

New Accumulator.—At the last meeting of the Paris Société des Electriciens a communication was made by M. d'Arsonval in reference to the Blot accumulator. This is made on the Planté system without the addition of oxide paste, and its novelty lies in the form of the plates, which are made of thin ribbons of crimped and grooved lead foil wound round a core so as to make flat bundles or rolls with one diameter very long compared with the other. The ribbon hangs by its own weight, so that within limits it is free to expand, or contract, or change its shape in the process of charging and discharging. This arrangement gives a very large active surface for a comparatively moderate weight of lead, three kilogrammes of metal giving a square metre of surface, or about 61lb. per square foot. The plates are protected by frames made of some metal not attacked by the liquid. M. Blot, the inventor, claims to have attained with plates constructed in this fashion an efficiency of 10 ampere-hours per kilogramme at the ordinary rate of discharge, and this, it appears, may increase with age to 19 ampere-hours. M. d'Arsonval, in his communication, described the results he had obtained from experiments with a Blot accumulator during the past year, and added that these were confirmed by the experience of Mr. Preece at the English Post Office. Mr. Preece, by way of an extreme test, short-circuited a Blot accumulator for 10 minutes so as to give a current of 200 amperes until the E.M.F. fell almost to zero. Then the cells were left for 12 days, and finally recharged to a standard of one ampere per kilogramme. Under these circumstances he obtained an ampere efficiency of 79·2 per cent. and a watt efficiency of 64·8 per cent. The plates were then taken out, washed, and dried. No precipitate was found at the bottom of the cells, and all the plates were in perfect condition. M. d'Arsonval added that the Blot accumulator seemed to lend itself readily to circumstances where the amount of work required was subject to great variations. On the other hand, it could be charged from power sources that were essentially variable and uncertain, such as windmills. He had charged a Blot accumulator on July 14 and left it until October 23, when he found that it had lost hardly any of its charge. Again, he had short-circuited the accumulator for 24 hours without finding any trace of deterioration. This ability to give very heavy currents would be of great service in electro-chemical work. According to figures obtained by M. Margain, the efficiency of the accumulator is 89 per cent. for a rate of one ampere per kilogramme, falling to 45 per cent. at 5·6 amperes per kilogramme. By way of showing the power of the accumulator, the hall was lighted for an hour by a platinum strip kept at incandescence by a current of 100 amperes derived from two cells.

New French Atlantic Cable.—In the January 25th number of *L'Electricien* the Bill for the new Transatlantic cable which has been referred by the Chamber of Deputies to the Budget Committee is printed in full. In the *exposé des motifs* which accompanies the Bill attention is drawn to the insufficiency of the French submarine telegraphic system and the inconvenience of relying on the cables of other countries. To accommodate the French traffic with America and the Continental traffic going through France there is now, it is pointed out, the single French cable from Brest to St. Pierre and the two foreign cables from Brest to Salcombe in England and from Havre to Waterville in Ireland, these two last lines carrying off for the profit of the Anglo-American lines a large amount of traffic which might with better facilities go direct from France. It is further observed that with a single cable it is impossible to guarantee a permanent communication, since the working may be stopped for a time by the slightest accident. The Compagnie Française des Cables Télégraphiques has for several years provided a system of telegraphic communication with places in the Caribbean Sea, and notably with the support of the Government has established connections with the French colonies in the West Indies. For a long time the Compagnie Française has desired a direct communication between this network and the United States, and is now about to carry it out. Under these circumstances the French Government has concluded an agreement with the Compagnie Française by which the latter are within two years to lay a new cable direct from Brest to Cape Cod in the United States, and at the same time to undertake to keep up and renew, when necessary, their existing lines from Brest to St. Pierre and thence to Cape Cod, and also the line from St. Pierre to Cape Canso. The company are also, within two years, to provide a submarine connection between its Atlantic cables and the West Indian lines, so as to complete their network, there being at present no communication between the Atlantic and West Indian portions except over foreign lines. The duration of the agreement is fixed at 30 years, and the Government subvention will be 800,000fr. per annum, but the Government will be entitled to deduct from this sum two-thirds of the excess over 1,650,000fr. of the gross receipts on the working of the Transatlantic cables. Government telegrams are to have preference, and to be carried at a reduction of 75 per cent. on the ordinary rates for the Transatlantic lines, and 50 per cent. on the West Indian lines. If an interruption occurs for more than 24 days on either of the lines constructed under the agreement, the Compagnie Française becomes liable to a fine of 1,000fr. a day counted from the first day of the stoppage, and a fine of 500fr. is imposed under similar conditions for an interruption on the cables between St. Pierre and either Brest, Cape Cod, or Cape

Digitized by Google

Canso. If this stoppage lasts nine months the fine becomes one of 1,000fr. a day.

Institution of Junior Engineers.—The eleventh annual dinner of the Institution of Junior Engineers was held on Saturday evening last at the Westminster Palace Hotel. Mr. Archibald Denny, the president, was in the chair. Among the guests present were Sir Donald Currie, M.P., Mr. J. M. Denny, M.P., Mr. James Dunn (acting director of naval construction), Mr. A. J. Durston, C.B. (engineer-in-chief of the navy), Prof. J. Harvard Biles, Prof. C. J. Lambert, Prof. H. J. Spooner, Dr. John Perry, Messrs. E. Windsor Richards and J. M. Gray. In proposing the usual loyal toast, the President referred to the loss sustained by the Royal family in the death of Prince Henry of Battenberg, and Mr. J. M. Dunn, proposing the "Army, Navy, and Auxiliary Forces," said that the prince had died in the service of the country, and his memory should therefore be honoured like any of our past warriors. Mr. A. J. Durston, in reply, said that we could turn out ships in a manner unapproachable by any other country. Not only was our navy superior to all others, but our powers of production were so great that it was only a question of money to keep ahead of other nations in ships and munitions of war to any desired extent. The President then proposed "The Mercantile Marine" in a well-considered speech, which touched on the tremendous strides made in the art of shipbuilding during recent years. Sir Donald Currie, in response, said there was raiding and freebooting in the shipping trade as well as on land, and the dignity of the mercantile marine had sadly depreciated. Ships were not now sailed by the owners, as in the old days, and the competition under chartered rates did away with the personal interest of the owners. No industry had been so legislated against as the shipping industry, but in spite of the spasmodic bursts of humanitarian sentiment England still held her own on the seas. We were, however, behind other nations in valuing the mercantile marine as a serious adjunct to the Royal navy. But just as in the days of Queen Elizabeth the mercantile marine went to the assistance of the navy, so it would do now if occasion required. He regarded the present time as one of great difficulty in South Africa, but he trusted that all would come right. In due time the country would form an estimate of what had been done, and he wished also that the people would understand and comprehend the question at issue and the history of the republics in Africa. We drove the people of the Orange Free State from the arms of England, and formed them into a State against their will, although they begged us to retain them as British subjects. When the people of that Free State got into difficulties with the Basutos we interfered and divided Basutoland between the republic and ourselves, and when diamonds were discovered we took the diamond fields, acting just as we were acting now with regard to the goldfields. Time, kindly consideration, and good feeling gave better solutions of international and social difficulties than did appeals to violence. Other toasts were "Kindred Societies," by Mr. H. Bloomfield Varley, acknowledged by Mr. Richards and Prof. Biles; "The Institution of Junior Engineers," by Mr. A. E. Mavor, acknowledged by Mr. H. A. Young; and "The President," proposed by Mr. W. J. Hunter. The whole proceedings were carried out with a vigour which characterises the Institution of Junior Engineers.

The English Telephone Service.—Mr. Montague Guest has written to the *Times* of Thursday on the subject of telephonic communication. "While the National Telephone Company," he says, "is urging the public to erect telephones in their houses, at an annual rate far in excess of that in other countries, they are not, in my opinion, giving their subscribers the full benefits which are held out to them. It may be correct, and I believe it is so, that a subscriber can telephone to many parts of the United Kingdom, and even Paris, from his own room; but the difficulty arises, how is he to know who is on the system and who is not? The National Telephone Company issues a very meagre book for the metropolitan area, with the names of their subscribers, and in a very few instances their addresses, making it often difficult to be certain that the right subscriber is being called. In regard to any communication with the provinces through the trunk lines, which is held out to the public as an inducement to subscribe, it is well-nigh impossible for the public to find out to what part these trunk lines lead and who are the subscribers at the various towns. It is true that there are supposed to be books in existence which afford this information. I have been in communication, both personally and otherwise, with the National Telephone Company in regard to these books. I was told that they would be supplied at an extra charge of a shilling a book, and that there were five in existence, but though I agreed to take them I have as yet been able to obtain but two—viz., for the Midland province and the Scotland province. I was informed by one of the clerks at the district telephone office that they were very difficult to obtain, as few people wished to telephone into the country. Who can wonder at this when such sparing information is given to the public? Being unable to get a book to refer to I asked if a certain watering-place in the West of England was connected by a trunk line. I was absolutely unable to get any information on the subject. Now, it is absolutely necessary that the public should be able to know with what town and with what people in those towns they can communicate through the telephone. This could be very easily accomplished if the National Telephone Company would publish a book in one volume similar to 'Sell's Registered Telegraphic Addresses,' giving the information required." Mr. Guest adds: "What we want is that the National Telephone Company should realise their position in holding out inducements to the public to subscribe to their system which they are not able to avail themselves of through the neglect of the company in failing to afford the requisite information. There are public telephone offices throughout the country where any person may communicate on the payment of a small fee; but with the very limited information accorded by the National Telephone Company their usefulness is very much abridged." In Manchester the dissatisfaction with the telephone service has resulted in a requisition, which has already received the signatures of 1,000 of the leading firms in Manchester. This will be presented to the Lord Mayor, and his Lordship will be asked to submit it to the City Council. The requisitionists urge the desirability of the Corporation undertaking the telephone service, on the ground that the National Company's system is too expensive, and that the monopoly threatens to increase the present £10 rates. It is urged that the Corporation could now construct telephone exchanges upon a very small outlay; that a service could soon be carried on at a cost not exceeding £5. 10s. per annum for each subscriber; and that the reduced rates would probably lead to the number of subscribers being increased from 4,000 to 6,000, or 10,000 in a very few years. It is pointed out that at Stockholm, which has a quarter of the population of Manchester and Salford, there are 14,000 subscribers, at an average rental of £4 per wire, to the Corporation system. An influential committee of business men has been formed to advance the movement.

ELECTRICITY AT THE PANTOMIME.

Sir Augustus Harris has long been known as an expert in providing spectacular pantomimes, and year by year it is said that he has surpassed all previous efforts. The continued increase in the use of electricity in these popular entertainments enables him to readily increase and improve on previous efforts. The pantomime "Cinderella," now running at Drury Lane, and drawing houses such as a pantomime hardly ever drew before, contains more than one scene the effect of which is largely due to the use of electricity. Our artist, Mr. W. M. Bowles, has in the accompanying

Scene in the Pantomime of "Cinderella" at Drury Lane Theatre.

illustrations endeavoured to indicate the use of this illuminant, but no illustrations in black and white can give an adequate idea of the colour glow upon the stage. That must be seen to be realised; but by a strong effort of the imagination our readers may perhaps mentally picture the gorgeousness of such scenes. Our advice, however, would be, do not attempt the mental strain, but go and see the sight.

COLOGNE ELECTRICITY WORKS.

(Concluded from page 95.)

Returning to the arrangement of the network, it may be split up into parts by means of 30 mercury switches (Fig. 7). This is necessary for making new connections or repairs, as the network is a closed one. The type of connecting and branching boxes used is shown in Fig. 10. They and the rest of the network have given full satisfaction, requiring only very few repairs, nearly all due to mechanical damage done by the picks of labourers. Fig. 11 is a street plan of Cologne showing the mains now laid.

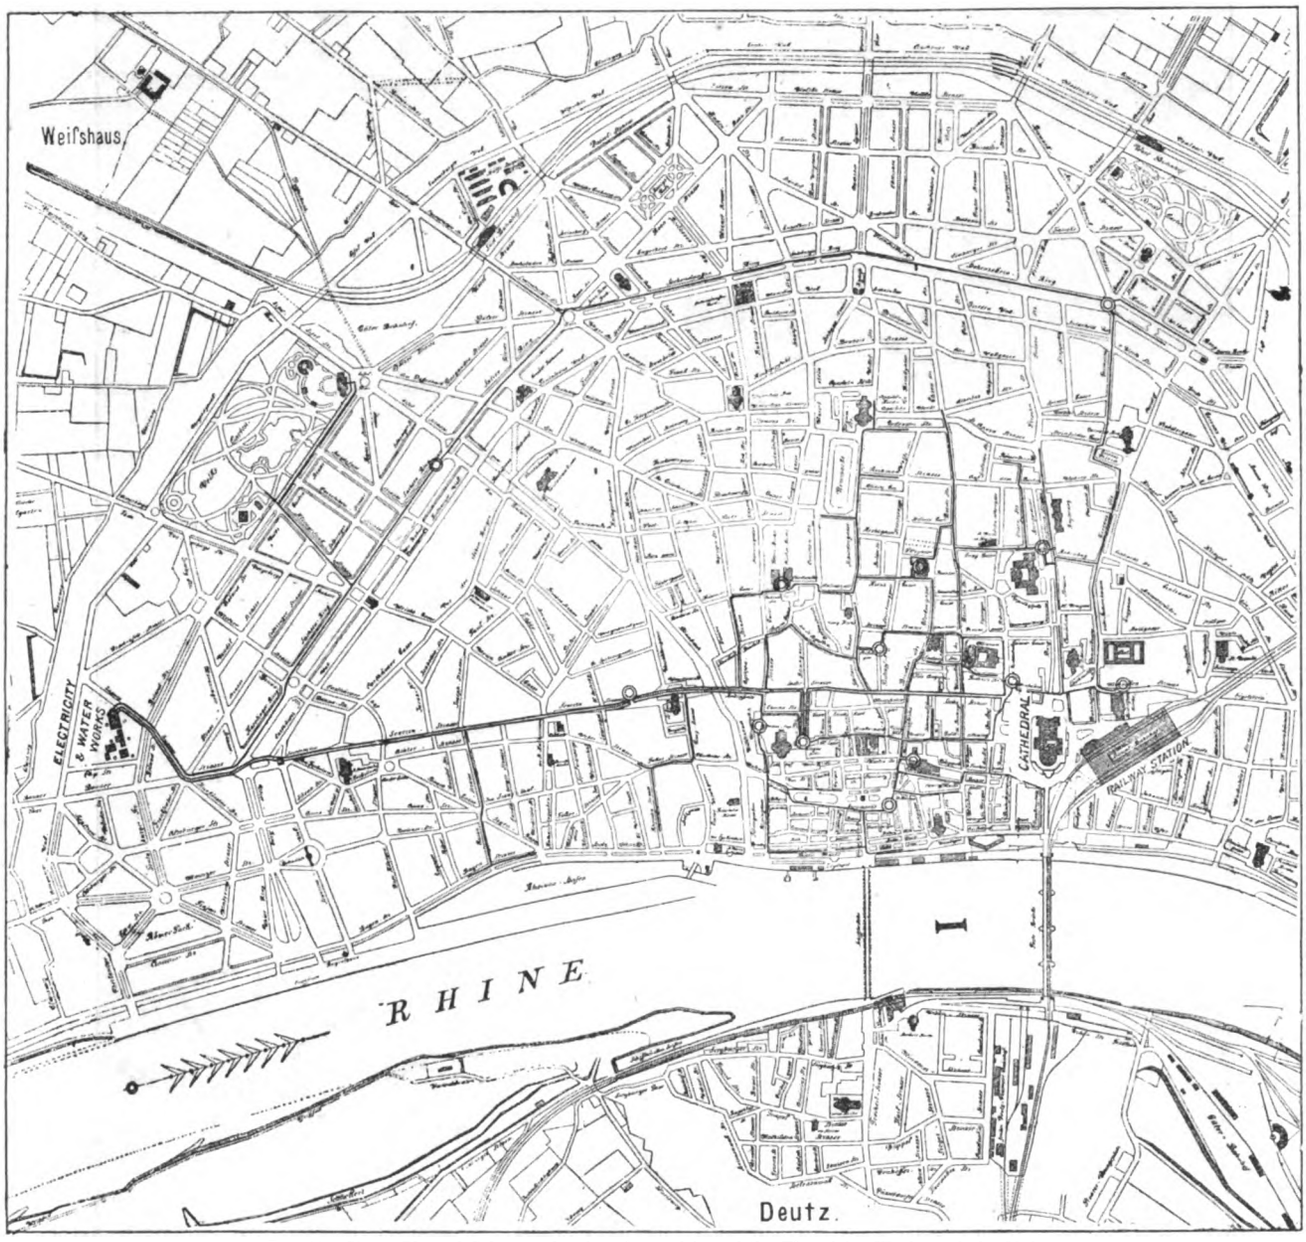

FIG. 11.—Street Plan of Cologne, showing the position of the Electricity Works and the Mains.

TRANSFORMERS, METERS, AND OTHER DEVICES.

Fig. 12 shows the arrangement of a transformer in the cellar of a house, including the T-joint and the part of the primary cable which must be paid for by the customer, but which remains the property of the municipality. The transformer is generally placed upon a bracket, and protected by means of a wooden partition wall, which may be entered only by the station employés. The secondaries of the transformer consist of two coils with 36 or 55 volts, thus allowing a three-wire system with twice those pressures to be used. The 2 × 36 volts are employed especially in conjunction with the Helios Company's arc lamp, which is extensively used in England also, and which gives a steady light with 28 to 30 volts at the terminals. The Helios lamp, which is sold in England by the International Electric Company, of London, has a small inside reflector immediately above the arc, which is protected from the heat by a layer of white enamel. It is almost the only type of alternating-current arc lamp that is used at Cologne for public or for street-lighting. The meters used are of Blathy's patent, and embody a practical form of two-phase motor. Their range is very wide, as the mostly-used 100-ampere type starts with one 16-c.p. lamp, and is correct within 2 per cent. from 5 up to 100 amperes.

Among the other devices used there is the alternate-current clock mentioned before, and represented by the following figures (13-15). It consists of a small synchronous motor, whose field has the special shape shown in Fig. 13, and whose star-shaped armature is built up of iron stampings without any windings. By grasping the button, *a*, and twisting it between the fingers the armature is easily thrown into synchronism, and during its synchronous revolution it actuates directly the clockwork and moves the hands of the clock. Thus the whole clock is of the simplest construction and mode of working, and, as self-oiling devices are employed, it has given full satisfaction. The construction of the motor was patented by Mr. Coerper in 1894, and bears the British patent number, 7,239. As long as there is current in the transformer from whose secondary the field of the clock is supplied, it will run exactly as a similar clock placed in the station; if, therefore, the latter is regulated once a day and brought in exact concordance with a good pendulum clock, all the synchronous clocks of the town will give the right and the same indications. The regulation of the first clock is performed most simply by adding to or lifting from the regulator of the Sulzer

Digitized by Google

engine a small weight. The variation of the speed thus produced is too small to be indicated by one of the ordinary tachometers, and is only a small fraction of one revolution per minute.

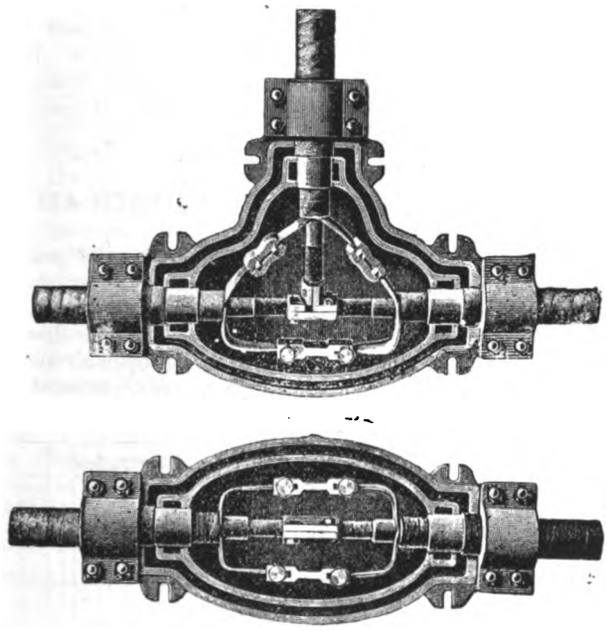

FIG. 10.—House Connecting Boxes.

FIRST COSTS.

The total amount of first costs was £97,424, and was distributed as follows:

Buildings	£21,202	14	0
Engines	11,660	16	0
Boilers	6 232	1	0
Dynamos	23.647	13	0
Network	23,582	0	0
Transformers	7.895	3	0
Meters	1 719	9	0
Measuring apparatus, tools, and instruments	469	8	0
Furniture	130	3	0
Cables and transformers on stock	885	7	0
	£97,424	14	0

It must be noted that there are no first costs for the ground, as the station was erected upon the ground belonging to the waterworks; for this it pays an annual rent of £150 to the waterworks.

FINANCIAL RESULTS.

The price for the kilowatt-hour at first was 80pfg. (9·6d.); on April 1, 1893, it was reduced to 70pfg. (8·4d.), and on July 1 to 25pfg. (3d.) for motive power. Large customers may obtain a rebate according to a somewhat complicated tariff, which was described at some length by one of the authors. The rebate increases by steps with the product of the sum paid into the number of hours during which the whole plant in question is used. Thus, a small plant with a high load-factor, such as a beerhouse, will obtain a higher rebate than the large plant of a private house, whose load-factor is small.

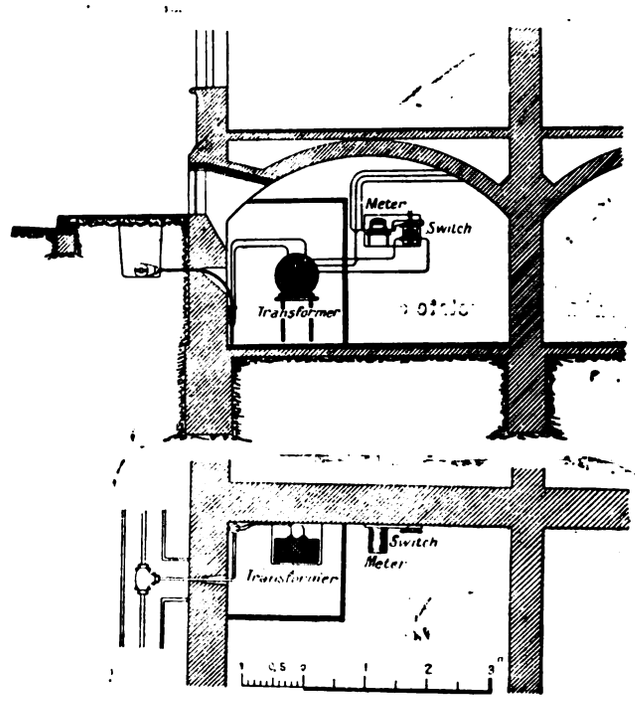

FIG. 12.—Details of Transformer Arrangements in a Private House.

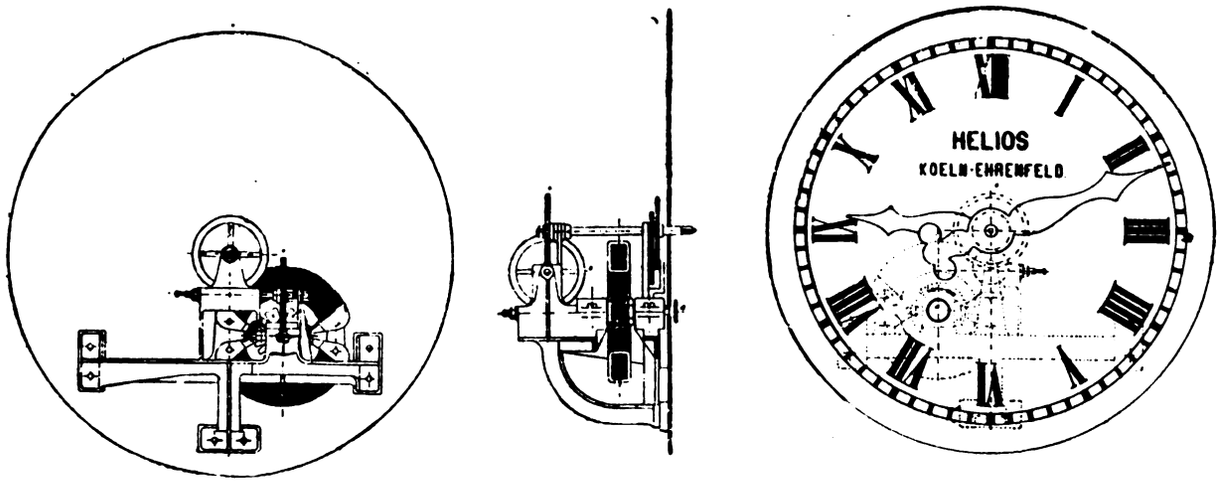
The following Fig. 16 and Table A show the continuous increase of the output and the corresponding decrease of cost of unit produced.

The costs of production are seen to decrease annually corresponding to the increasing output; the irregularity between the second half-year of 1891-92 and the following year is due to the fact that the station did not work day and night within the first half-year, and that a large number of tests were made in 1892-93. The station has no secondary network, but uses at present 260 transformers, with a total capacity of 1,900 kilowatts. In spite of this, the coal bill is not high. This is due to the small losses in transformers and network, and to the high quality of engines and boilers used; and partly also to the fact that these boilers are constantly working with about the same load.



FIGS. 13, 14, AND 15.—Alternate-Current Clock.

Of the total output of the central station, 90·46 per cent. is used by private customers, 88·75 per cent. being used for lighting, and 2·71 per cent. for motive purposes. The public illumination by arcs takes 3·71 per cent. of the output.

It is interesting to compare the relation between gas and electric light. The annual mean of the intensity of an Argand burner, taking 150 litres of Cologne gas per hour,

TABLE A.—TABLE OF COSTS AND REVENUE.

—	1891 92 Half-year.	1892-93	1893-94	1894-95
Total units sold	154,909	307,075	424,590	568,130
Cost of production in pounds	1,509	3 568	3,297	3 938
Actual receipts in pounds	5,819	10,636	12,854	16,297
Cost of production per unit in pence	2·34	2·78	1·86	1·66
Income per unit in pence	9 05	8·33	7·28	6·88
Cost of coal per unit in pence	·92	·77	·51	·51
Gross profit in pounds	4,310	7,067	9,557	12,359
Net profit	3,061	1,980	4,474	7,052

was 17 amylacetate candles; one cubic metre of gas would therefore be equivalent to $\frac{1{,}000 \times 17}{150} = 112$ candle-hours, if burnt in such a burner. Now, a 50-watt incandescent lamp gives 16 candles; half a hectowatt-hour would thus be equivalent to 16 candle-hours, and therefore one cubic metre of gas would give the same quantity of light as $\frac{112 \times 0{\cdot}5}{16} = 3{\cdot}5$ hectowatt-hours; the quantity measured in lumen-hours, according to Prof. Blondel's propositions, would be $4\pi \cdot 112$, as the amylacetate candle is very nearly equal to Prof. Blondel's pyr, or unit of intensity.* One cubic metre of gas costs 16pfg.; one hectowatt-hour costs 7pfg.; for equal quantities of light the prices are in the relation $\frac{16}{3{\cdot}5 \times 7} = \frac{2}{3}$.

If in this way the total output of the electric station and the gasworks is compared, we easily find that the former amounts at present to 7 per cent. of the latter. Of 1,000 inhabitants only one has the electric light in his rooms, and his plant embraces 64 lamps, while 42 have gaslight, and each installation contains 15 lamps. The total length of electric cables (on April 12, 1895) was 17 miles, that of the gas-pipes was 150 miles; the number of public arcs, which has since been increased, was 15, and the number of public gas lanterns 6,400. The descriptions in this paper are to a large part based upon a book, entitled "Die Beleuchtung und Wasserversorgung der Stadt Köln" ("Lighting and Water Supply of the City of Cologne"), by F. Poly, assisted by E. Froitzheim, Dr. Hansen, and W. Tellmann.

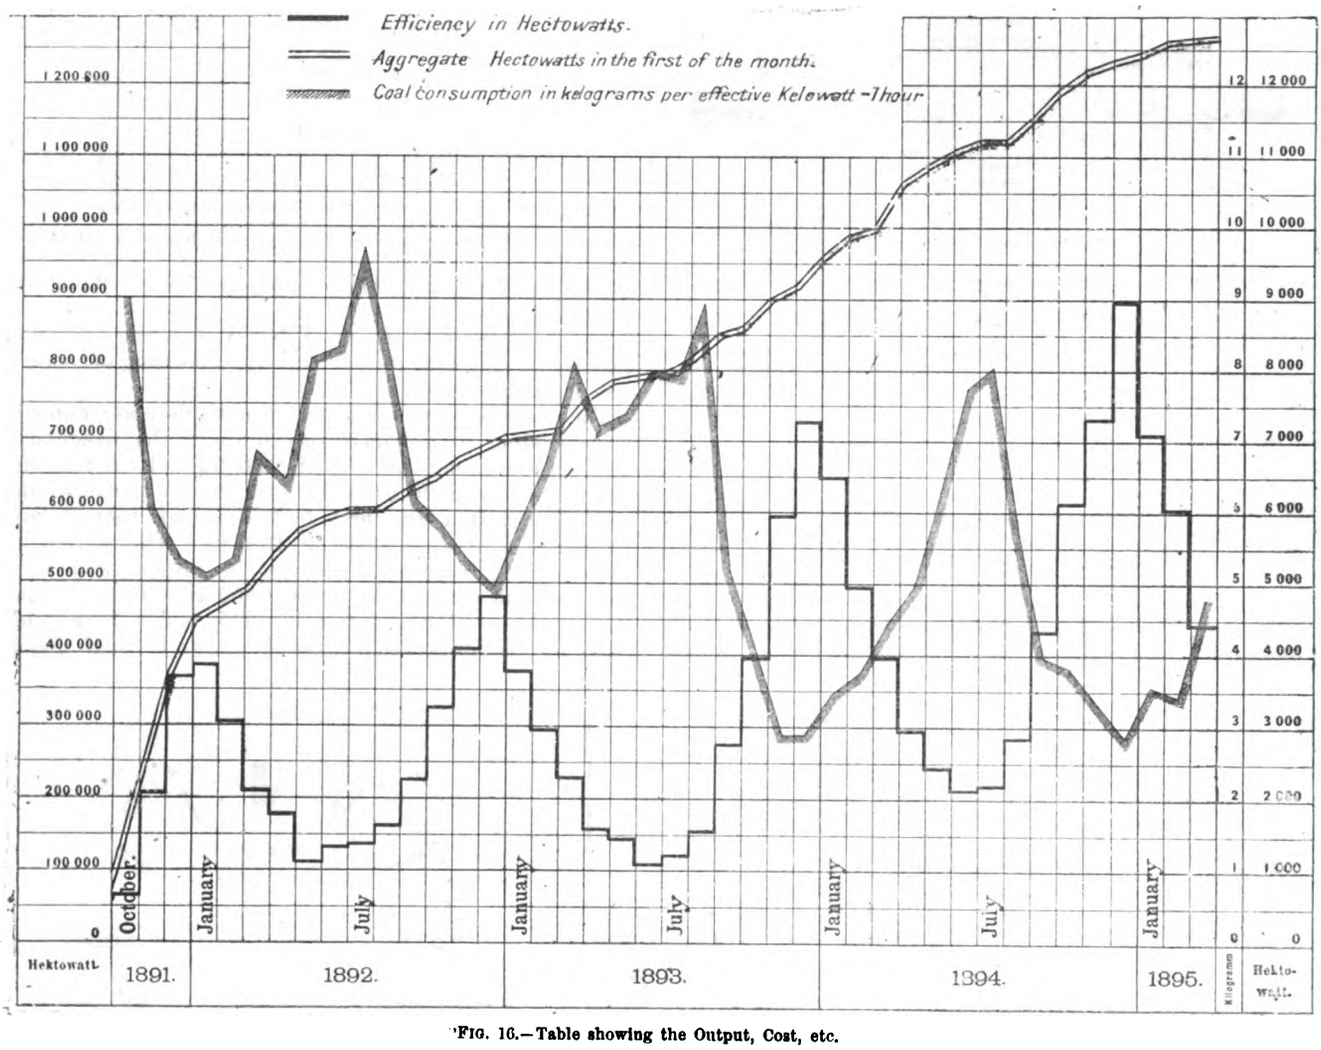

FIG. 16.—Table showing the Output, Cost, etc.

THE MARKS VENTILATED ENCLOSED ARC.*

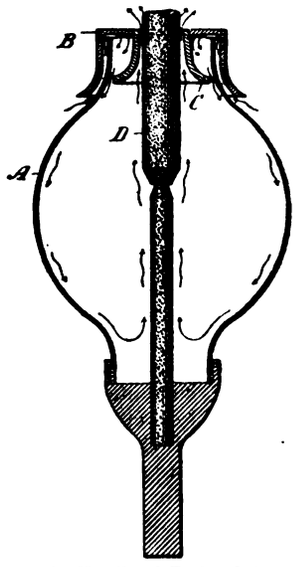
The shortening of the arc for a given drop of potential due to surrounding the arc by an enclosing medium and excluding oxygen, has made it necessary in the commercial operation of enclosed arcs to employ a higher drop per enclosed arc than would be necessary for open-air arcs, for a certain length of arc is required in order to produce a steady light, and in the case of the enclosed arc a greater potential difference is necessary to secure this length of arc than in the case of the open-air arc. This follows naturally from the increased resistance of the enclosed arc. If the attempt be made to operate the enclosed arc at as low-potential drops as open-air arcs, unsteadiness of the light results. Because of the flattening of the carbon points due to being consumed in the absence of an oxidising agent the light is largely obscured, and the illumination effective only in a small zone. Moreover, if operated at as low a potential drop as an open-air arc, the negative electrode invariably builds and a mushroom-shaped formation results. This formation consists largely of graphitic carbon. The nib thus formed breaks off eventually at its neck, and flickering and unsteadiness of the light results.

* Compare also F. Herzog and C. P. Feldmann, "Vertheilung des Lichtes und der Lampen," Berlin, 1895.

* From the *Electrical Engineer* (New York).

Digitized by Google

To avoid these difficulties, Mr. Louis B. Marks, of New York, whose work in this field is well known, has designed an envelope in which a limited circulation of air takes place, and which is illustrated in the accompanying engraving. The envelope, A, is provided at the top with a loosely-fitting cap, B, touching the cylinder only at four projections, in the centre of which is a circular or conical tube, C, through which the positive electrode, D, is fed to the arc. The negative electrode, by reason of its slower rate of consumption, may be smaller in diameter than the positive. The outer portion of the cap is enlarged into a bell-shaped flange, the rim of which is brought closely adjacent to the exterior wall of the envelope. Thus there is provided a narrow annular passage for the outside air into the envelope, one of the walls of this passage being formed by the envelope, which, by reason of its high temperature, heats the entering air in transit into the envelope. The tubular opening through which the electrode feeds is made slightly conical in shape, the enlargement at the top being only a little greater than the diameter of the electrode, so as to permit a free feed of the latter and to afford an obstructed egress for gases from the envelope. The lower part of the tube is flanged away from the electrode as shown, this form serving as a deflector for the upward currents around the positive carbon, the flange at the same time forming a deflecting wall for the ingoing air, and directing the latter



Marks Ventilated Enclosed Arc.

outwardly towards the walls of the envelope. The tendency with this arrangement is for all egress to take place by way of the central tubular opening and all ingress by way of the bell-shaped chamber. The arrangement of the cap as above described deflects the ingoing air into the downwardly-moving portion of the convection current, where it is intimately mixed with the gases already formed in the envelope and raised in temperature, so that it is intensely hot by the time it reaches the arc.

A highly important result which follows from the distribution of air currents as described is that the resistance of the arc stream, instead of being considerably increased, as is the case with other enclosed arcs, remains practically the same as in an open-air arc. The length of arc for a given drop of potential is therefore practically the same as that of an open-air arc of the same drop of potential. Because of the flow of convection currents of arc gases admixed with atmospheric air the electrodes do not burn blunt as in ordinary enclosed arcs, but have much the same shape as points formed in open air. The crater formed in the positive is substantially uniform in curvature, while the apex of the negative is quite pointed and well centred with reference to the crater of the positive. Thus there is practically no obscuration of light as in the usual enclosed arcs where the electrodes burn to blunt points. The light is steady and efficient at practically as low drop of potential as with open-air arcs.

Lamps with this type of envelope can be run at 45 or 50 volts, and the carbons have a life of 50 hours.

SOME CHARACTERISTICS OF SYNCHRONOUS MOTORS.*

BY E. KOLBEN.

There are many members of the electrical profession who are of opinion that the synchronous alternating-current motor is a very sensitive driving apparatus, and that it needs careful watching, especially under considerably varying load. Thorough theoretical investigations as to synchronous motors are to hand in great number, but little is known that refers to results under practical working conditions, or to show how greatly this type of motor is capable of being employed even for difficult work. A contribution to the practical knowledge is given below.

Mr. W. M. Mordey, in his paper read before the Institution of Electrical Engineers, February 22, 1893, has already characterised the behaviour of the synchronous single-phase motor with variable excitation in the well-known "V" curve. Far more marked, and more convenient for practical purposes, is the behaviour of the synchronous three-phase motor. Fig. 1 gives the "V" curves of a 15-h.p. three-phase synchronous motor when running with no load and with various loads. Fig. 2 represents the watt consumption of the respective points of the "V" curve, measured by a wattmeter. These curves show, first, that the minimum armature current is found with constant primary pressure for all degrees of load between no load and full load, and even when overloaded under almost constant excitation. Therefore, a regulation of the excitation under even sudden alteration of load is not necessary. Second, that even very considerable deviations in the excitation with any load do

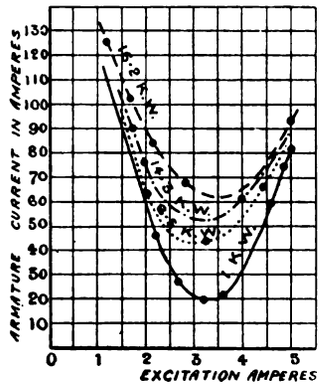


Fig. 1.—Current taken by 15-h.p. Synchronous Motor, with varying excitation at constant loads.

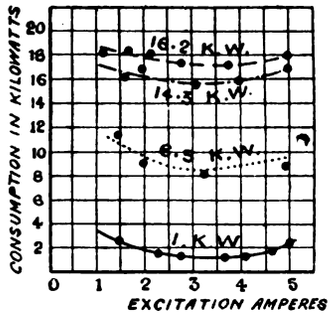

Fig. 2.—Watt Curves for the same 15-h.p. Motor, with varied excitations.

not change the mechanical power of the motor, and that the watt consumption for the same load remains nearly constant: therefore the efficiency of the motor within the extreme limits of excitation is fairly constant.

The most favourable excitation, for instance, in the experiments especially represented in Figs. 1 and 2 amounted to 3·3 amperes, in which case the current and watt consumption becomes a minimum. Given, now, a fall of the excitation current to one ampere, or raised to five amperes, the consumption of current would then suddenly increase at both sides of the most favourable excitation, but the watt consumption would vary very little even in the case of a very strongly over or under excited motor. Of course, this is only a characteristic quality of a good synchronous motor—*i.e.*, such which has only little self-induction, and which, as a generator, would work with a small fall of potential between no load and full load. With a motor with much armature reaction the watt consumption increases extraordinarily with increasing armature current, in consequence of the great reaction of the alternating current in the armature upon the impressed rotating field, as the reacting magnetic field produced by its means creates Foucault currents. How considerable the influence of the armature reaction currents can be is to be seen by the curves of the watt consumption (Figs. 3 and 4) of a good and a bad motor or alternator respectively, when the armature is short-circuited with increasing excitation and armature current. The good watt curve on short-

* From the *Elektrotechnische Zeitschrift*.

Digitized by Google

circuit (Fig. 3) includes, besides the losses in copper, which can be neglected, mainly losses of hysteresis. The losses in the bad motor, however (Fig. 4), are principally due to eddy currents. The former has the shape of the well-known hysteresis curve of the 1·6 power, the latter the

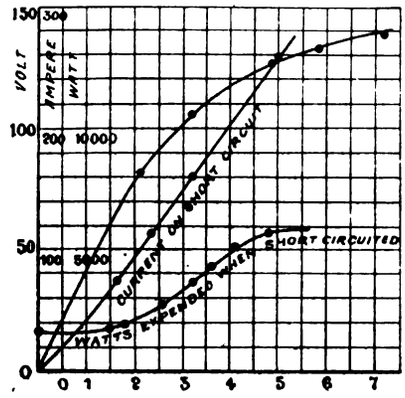

FIG. 3.—Curves for 30-h.p. Three-phase Synchronous Motor.

shape of the eddy-current curve, which rises very quickly with a small increase of excitation.

The value of the machine as a motor and generator can easily be found by the "V" curve, when the synchronous motor runs with no load, and likewise by the short-circuit characteristic curve given below. The steeper the two arms

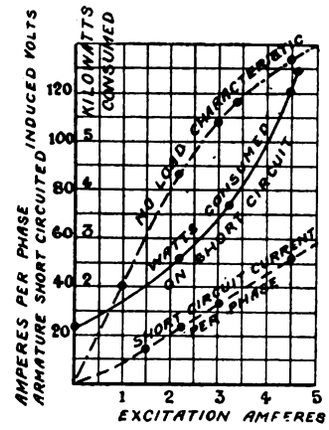

FIG. 4.—Curves for 30-h.p. Motor, with strong armature reaction.

rise—*i.e.*, the quicker the armature current increases with over or under excitation—the better suited is the type of machine, not only as a synchronous motor, as regards falling out of step during sudden load variations, and during overloading, but also as a generator for inductive loads, especially with reference to fall of potential. It is

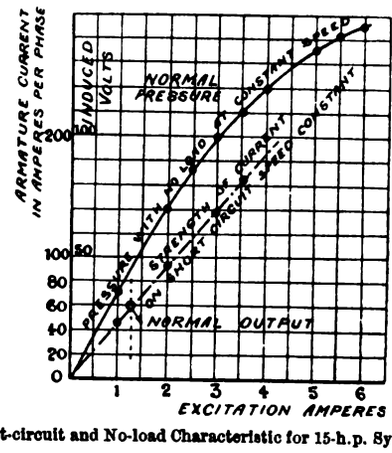

FIG. 5.—Short-circuit and No-load Characteristic for 15-h.p. Synchronous Motor

only such motors, with good "V" curve and short-circuit characteristic, which, as Mr. J. Swinburne suggests, can be used with advantage as no-load current generators, or phase regulators—*i.e.*, as over-excited synchronous motors with no load. The current component having a lead generated thus can be used for supplying big systems, with many smaller and only partly loaded motors, with the wattless or no-load current. In this way the distant transformers and primary machines are relieved of the latter—*i.e.*, no-load current—to the advantage of the whole installation. By this means the efficiency factor (cos ϕ) is increased, and the

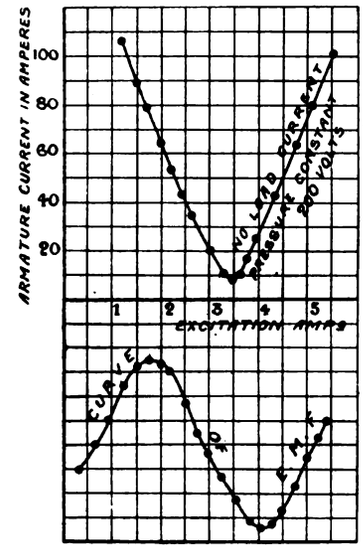

FIG. 6.—"V" Curve and E.M.F. Curve of 15-h.p. Motor, with sine-shaped curve from generator.

otherwise considerable inductive fall of potential in the aforesaid parts of the installation is greatly reduced.

Highly characteristic, as regards the behaviour of the synchronous motor, is the variation found in the armature current when short-circuited with varying excitation. The greater the armature stray field, the smaller will be this strength of current, with otherwise equal excitation, in consequence of the counter E.M.F., produced by the strong counter-field of the armature. The good synchronous motor, which can stand much overloading, has generally a weak armature field, and therefore a short-circuit characteristic, and showing even with small excitation a quickly increasing strength of current. An example of this is shown in Fig. 5, the no-load characteristic with corresponding short-circuit curve of the synchronous motor above mentioned. The following can be taken as a sufficient approximation: The motor can be pronounced good when the armature is short-circuited and the strength of current of full load is reached with an excitation which, with open

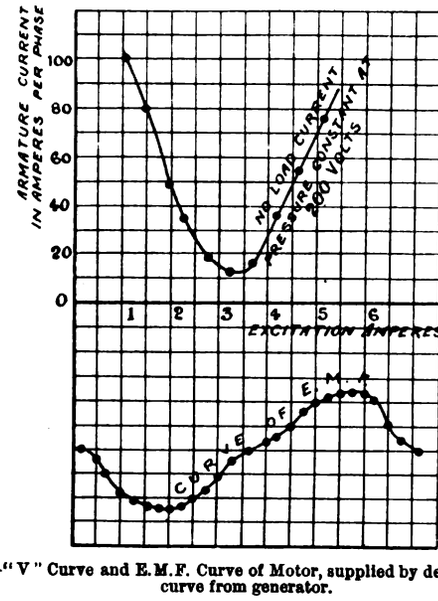

FIG. 7.—"V" Curve and E.M.F. Curve of Motor, supplied by deformed-shaped curve from generator.

armature circuit, would produce about one-third of the normal driving pressure. With the assistance of this useful short-circuit curve the fall of potential of the machine as generator on inductive loads can also be fixed.

The shape of the curve of the E.M.F. of the motor itself, and likewise of the primary machine, is not without

Digitized by Google

importance with synchronous motors. In shape the curves will be found to generally agree when the generator and motor are similar to each other in construction. The angle of the "V" curve at minimum point, which has been received from the synchronous motor under most favourable excitation, will then under all loads nearly coincide with the watt current. If, on the other hand, motor and generator vary in construction—one machine, for instance, giving a sine curve of the E.M.F., and the other a deformed pressure curve—then the angle of the "V" curves on all loads will increase, and the efficiency factor ($\cos \phi$) will be reduced even under most favourable excitation, in consequence of the wattless current component of the pressure curve between the two machines.

Their numerical result is easily calculated by graphically detailing the deformed curve into the equivalent sine curve and its threefold harmonics, or wattless components, and then finding out the mean pressure ordinate of the latter,

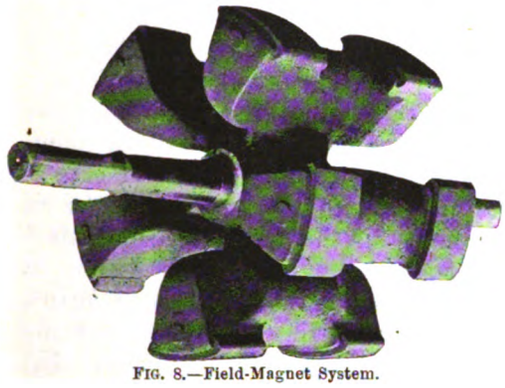

FIG. 8.—Field-Magnet System.

The working of synchronous motors with the various good qualities mentioned above is very simple and certain, if the motors are constructed after the modern type of alternators without rotating winding, thus reducing the supervision and depreciation to a minimum. Fig. 8 gives a view of the rotating parts. Fig. 9 shows a complete 60-h.p.

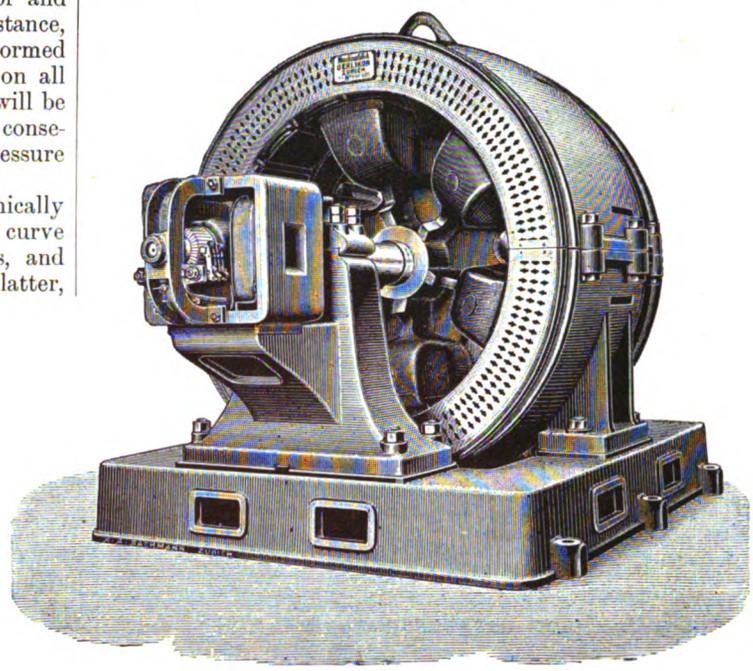

FIG. 9.—Oerlikon 60-h.p. Synchronous Motor.

with the assistance of the no-load E.M.F. characteristic and the corresponding short-circuit current curve (Fig. 4) of the machine fix the resultant strength of current. Figs. 6 and 7 are the "V" curves drawn for variously-shaped curves of the generator, observed on the synchronous motor referred to, which had been taken by the revolving contact

synchronous three-phase motor for 3,000 volts, of the Oerlikon Construction Company's type. In consequence of the good magnetic arrangements of the machine, it can hardly be got out of step, and works with good efficiency, as the energy of excitation is small on account of the one-coil excitation. There is only a small magnetic loss because of

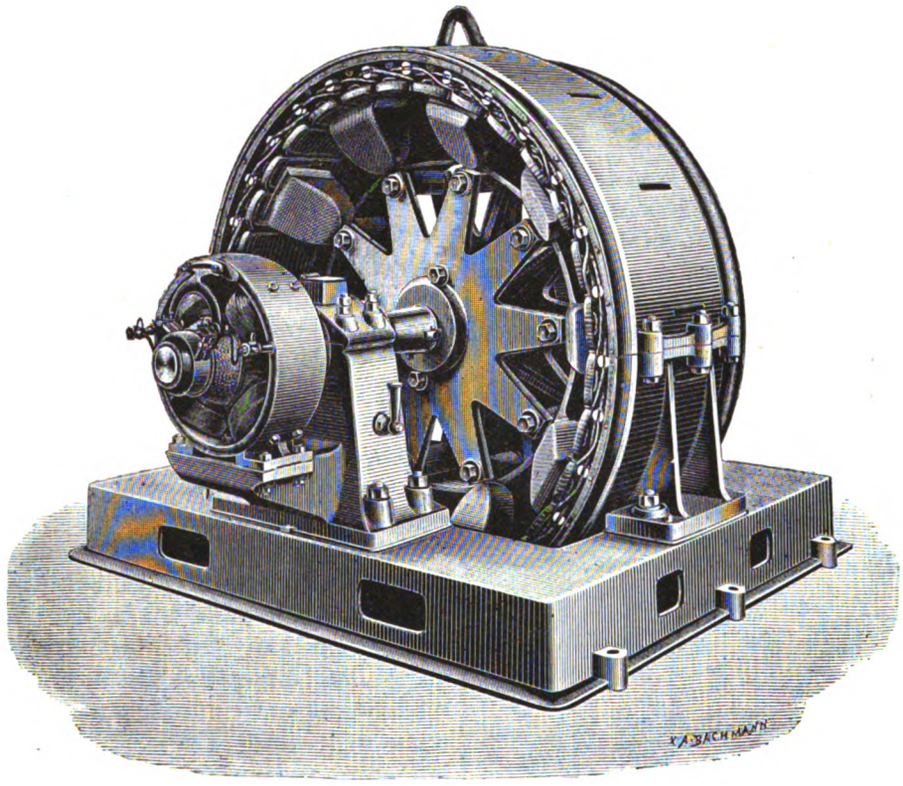

FIG. 10.—Oerlikon 300-h.p. Three-phase Generator.

method. As this method needs a good deal of preparation, it is a good plan, in order to ascertain the value of the pressure curve, to have a small synchronous motor at hand which gives a sine E.M.F. curve. Then take the "V" curve of the same with no load, and see if the strength of current in the angle of it very nearly corresponds with the watt current or not.

the ample dimensions of the armature iron. These qualities make this type of machine also especially valuable as a generator, and its simplicity of construction recommends it equally well for the smallest as well as for very large machines. Fig. 10 represents a larger machine—viz., a 300-h.p. three-phase generator for 5,000 volts pressure, as made by the Oerlikon Construction Company.

BOUND VOLUMES.

Vol. XV. of new series of "The Electrical Engineer" can be had bound in blue cloth, gilt lettered, price 8s. 6d. Subscribers can have their own copies bound for 2s. 6d., or covers for binding can be obtained, price 2s.

IN THE COURT.

Compared with the modern society journal, we are pleased to say that technical journalism is free from lawsuits relating to libel. When one does occur it appeals to every professional man as an exceptional circumstance. The case between Mr. Cuthbert Hall and the proprietors of our contemporary the *Electrical Review*—decided in favour of the former on Wednesday—may, we trust, form an excuse for us to touch upon the responsibilities and the difficulties of editors of technical journals, and especially of electrical journals. One of the greatest difficulties is due to thoughtless human nature. Every man has naturally a desire to see criticisms upon works of others, and does not object to adverse criticism in that case, while upon his own works he expects nothing but flattering words. Apply any other words, and he is personally affronted. Let us put the particular case that leads us to moralise on one side for the moment. Upon it a jury has given a verdict, and we desire to say neither yea nor nay to the verdict. What we do wish to point out is this, that respectable journals—journals that assume they have a reputation at stake—are most determinate to criticise a man's public works without intending to impute anything against the man personally. It is seldom that the editorial "we" stands instead of "I," but most often that it really puts concretely an opinion expressed by a number of individuals whose views have been ascertained upon a particular subject. There are questions of public interest, of professional etiquette, of scientific investigation, and so on, that have to be discussed, and it is extremely seldom that one departure from recognised custom will lead to editorial comment, but a particular incident occurring after a number of similar incidents may bring the editorial mind to the position that it determines the subject to be now one of sufficient interest to be discussed with the full weight of the journal's influence on a particular side. Let us take the case just decided as an example of what we are driving at. The older professional men among us can recollect the years in the early eighties. They recollect how dreadfully the general public suffered from the exploitation of patents and companies. If we have read the signs of those times aright and the minds of the men who went through that period of technical journalism, we imagine each of those men will say they fully made up their minds to try to guard the public against hurried investment. Prospectuses and reports became to be looked upon with the direst suspicion. It is extremely easy, then, to realise how imperative the duty seems to be upon the advisers and controllers of technical journals to warn their readers against what they may deem immature or incomplete conclusions. While we cannot but sympathise with any professional man who forms the exception which proves the rule, we cannot help sympathising with brother journalists who we believe hold these views when they make the unfortunate mistake. It is unmitigated nonsense to speak of the responsible controllers of the foremost technical journals as unpractical. We

Digitized by Google

think we know the internal economy of many of these publications, and dare venture to say that a more practical body of men could not be found than the men forming the editorial staffs of these journals. They are far more conversant with general progress than any men employed with a particular firm, because they have to investigate a variety of work and not stick to specialities. It is far easier, then, for them to judge the value of a new design or a new invention than most other men, for seldom in design or invention is the departure from what has gone before so great that its value will not previously have been indicated by the attempts made to solve the problem. Most emphatically, again, it is not necessary to have even laboratory or workshop knowledge to condemn certain statements in the strongest language. Let us venture a concrete example, libel or no libel. The *Electrical Journal* of Chicago has the following sentences among others: "Mr. Edison's suggestions for coast defences in case of war are the subject of an article in the New York *World* of December 29. "One suggestion is to run out cables, the extreme end being about fifteen miles from the shore. These cables would run on wheels placed at the bottom of the ocean, and to them at intervals would be attached torpedoes of great destructive power. It is proposed to move the cables back and forth from a subterranean workshop." Now, we cannot justify an adverse criticism of these sentences. We have not tested the matter in a laboratory or otherwise, and yet we do not hesitate to dub the suggestion as enough to damn the author of these as a scientific inexpert. If he is a professional man, he is both ignorant and incompetent. Our readers may remember how Edison's name was used to get up a boom against gas. Now, it has been used again and again for purposes no honest man could praise. Can we, then, as responsible professional men ignore such statements or hesitate a moment in calling attention to their absurdity? We do not believe that Edison himself is concerned in these usages of his name.

Another difficulty in the way of editorial criticism is that the ranks of professional men contain both young and old. The former are lacking experience, but possibly have more energy than the latter? Our own opinion is that the technical journals should constructively as well as destructively criticise; but some men object to be lectured to like schoolboys. Finally, then, we maintain that the higher-class technical papers will not, and do not, allow personal considerations to influence their columns. Their desire is rather to guard the public against capital losses, and to give due credit to every man for his work.

CORRESPONDENCE.

"One man's word is no man's word,
Justice needs that both be heard."

THE NEW "RAYS."

SIR,—May I point out that the recent experiments of Prof. Röntgen confirm in a most striking manner the view that you were good enough to allow me to put before your readers, three years ago, as to what electricity, magnetism, electromagnetism, and chemical action really are. As your readers will remember, the view I take is that all of these forces, as well as sound, light, and heat, are modes of motion, either of the molecules of the bodies themselves or of the ether—that they are apparently all wave motions, their different properties varying with their different wave lengths and their different rates of transmission.

Electricity I place not far below the waves we know as invisible heat waves, the infra-red and electromagnetism as above the waves we know as the ultra-violet. That is to say, I view an electric current as a series of waves whose wave lengths are longer than the largest of the invisible heat waves, and whose rate of transmission is lower than that of those waves; while what we know as electromagnetism consists of a series of waves shorter than those we know as the ultra-violet rays, and whose rate of transmission is higher.

Magnetism I look upon also as a wave motion imparted to the molecules of the iron at their formation, or to the ether surrounding and forming part of those molecules, the motions taking place within the closed figures formed by the molecules when the iron is not in the state we call magnetic, and the wave motions being set free by the impressed electromagnetic waves brought to the neighbourhood of the iron by the electric current.

The nature of the motion we know as chemical action is not so easy to place, but it will probably be between the wave length and transmission rate of the highest sound waves and those of electricity. What we know as chemical elements I look upon as matter endowed with special rates, and possibly special forms of motion of their molecules and of the ether, and having special properties in virtue of these special modes of motion. Prof. Röntgen's rays appear to me to occupy a place that might be termed ultra-electromagnetic—that is to say, there will necessarily be a range of motions comprised within what we term electromagnetism, some being comparatively slow in transmission and of comparatively long wave lengths, while others will be of shorter wave lengths and higher rate of transmission. Prof. Röntgen's X rays I believe to be very short electromagnetic waves. It would also be well within probability if some waves are longitudinal and some transversal.

The reasoning that has induced me to take the above views would take long to furnish in detail, but one very striking feature may be mentioned. Whenever we confine bodies in motion without depriving them of the energy in virtue of which they are in motion, we necessarily reduce the amplitude of that motion, shorten its wave length, and at the same time increase its rate of vibration and of transmission. Thus, if a falling body is suddenly brought to rest by impact with the earth, the major portion of its motion of translation is instantly converted into the molecular and ethereal motions we know as sound, heat, and sometimes light. When we heat a body—say, a piece of iron—at first the heat waves are long, and their periods also long, while the rays emanating from the heated body are invisible. As we add heat to the body the waves become shorter and the periods shorter, and this goes on as the body becomes hotter and hotter, the heat waves becoming visible as red, yellow, violet, etc. Also, if we take one of the invisible heat waves and allow it to pass into a body such that the wave motion is confined, instantly the waves become shortened, their period shorter, and the body becomes visibly heated. What we do in the case of the falling body, in the case of the body to which we apply heat, and in that of the body which confines the heat wave, is, we oblige the waves to become shorter and necessarily faster.

And this may be applied to the whole range of molecular and ethereal motions. Pass what we call a current of electricity through a conductor, or, as I understand it, a series of electric waves. While the number of waves passing in a given time is small, or, as we say, while the current density is small, the effect upon the conductor is very trifling; but as we increase the current density, in other words, as we confine the waves, they become shorter, their periods become shorter, and, in fact, they cease to be electric waves; they become heat waves. As we know, we may continue the process by means of suitable apparatus, till, as in the arc, nearly the whole of the electric waves

Digitized by Google

are converted into heat and light waves. But there is also necessarily another series of operations going on.

The major portion of the energy, or the motion, present in the electric wave passes by way of the conductor, because it is the easiest path; but, as we know, each wave not only moves forward in one direction—it moves in all directions, one direction being the circular path round the conductor in which the electric wave is passing, with which we are all so familiar. Necessarily, here a transformation takes places, just as a transformation takes place when we add heat continuously to an iron bar, just as a transformation takes place when a falling body strikes the earth, and just as a transformation takes place in the arc, and for the same reason. We have not been able to prevent the escape of the wave entirely, but we have retarded it very considerably, and consequently we have shortened its wave length, and also shortened its period very considerably. If this reasoning is correct, then it must only be a matter of degree to arrive at what Prof. Röntgen has termed his X rays. Further, as the properties of sound waves differ from those of electric waves, and as those of electric waves differ again from heat waves, and heat waves from light waves, each increase in the speed of the vibration, whether of the molecules or of the ether, bringing its own special properties, so we should necessarily expect that as the rate of vibration of the electromagnetic waves increases, so will they develop new properties.

On bringing this matter before an eminent professor a few weeks since, he challenged me to show proof that an electric current is a wave. Here is my answer. Take the case of an electromagnet. When no current is passing round its coils its molecules form closed paths, satisfying each other's attraction, as we say; or, as I prefer, forming paths for the wave motions present. When what we call an electric current passes, the molecules break away from each other, turning in the direction of what we term the lines of force. If the current ceases, the molecules swing back to, or nearly to, their original position. If the current strength is weakened, the molecules turn back partially; if the current is strengthened, they move farther forwards. I think a little consideration will show that the state we call magnetic, the strained position of the molecules, can only be maintained by a succession of impulses following each other in rapid succession, and that these impulses must be furnished by the electric current passing in the coils of the electromagnet. In other words, what we call an electric current is really a series of waves following each other in rapid succession and sending out other waves—the waves we know as electromagnetism—which keep the molecules in a position that is the resultant of the force exercised by these waves and that already present in the molecules themselves. The case of the action of the electromagnet upon the molecules of iron is similar to that of a stream of water falling through a waterwheel, or to that of a ball suspended in mid-air upon the summit of a jet of water.—Yours, etc.,

Cardiff Electrical Works, January 20, 1896.

USEFUL INCANDESCENT LAMPS.

SIR,—On the 16th and 17th inst. I read with considerable interest the articles and correspondence in the *Daily Telegraph* on the subject of "Worthless Electric Lamps," and simultaneously with this publication there appeared in the *Electrical Review* a certain advertisement emanating from a firm connected with the trade also tending to disparage German and Continental made incandescent lamps. Referring to your comments on the subject in your issue of the 24th inst., I have reason to believe that both the articles and the advertisements are inspired by the same parties, who, if my suspicions are well founded, are not an English firm, but are themselves "made in Germany," though cloaked with the cover of naturalisation. They have certainly chosen a good time for attacking the manufacturers of their Fatherland.

You will see from my signature that it is in the interests of "fair play" that I take the liberty of submitting to you the following facts, and as a constant user of electric incandescent lamps, I consider myself fully entitled to give my opinion on the subject, which I am in a position to bear out technically.

The electric light, especially the electric incandescent light, is looked upon by most people of sound judgment as a commodity of immense value, both for health and comfort. The extension of electric incandescent light was unduly kept back in England as long as the Edison patents existed here, and more than one of the most prominent electrical engineers of this country hailed the expiration of the aforementioned patents, and the subsequent influx of foreign incandescent lamps, as a blessing and a boon. It stands to reason that besides a great number of thoroughly reliable incandescent lamps imported from Germany, France, Belgium, Holland, and Austria, a certain amount of rubbish was also brought into this country and sold at prices which not only do not admit of a manufacturer's profit, but prove in themselves the bad quality of the merchandise offered. There are, however, firms in existence in Germany and elsewhere who can compete in quality—leaving the matter of price out of the question altogether—with any incandescent lamp made either in America or England.

There is not, perhaps, a single Act or law in existence which has served so much to advertise foreign manufactures in England as the so-called "Merchandise Marks Act," which requires under certain specified circumstances that the goods be marked according to their origin, and the old idea that everything "made in Germany" was bound to be of inferior quality has long ceased to have any truth in it, as I for one strongly maintain that, for instance, the electrical industry, especially as far as electrical tramways and electrical transmission of power is concerned, is infinitely more developed in Germany now than it will be in England for the next 10 years to come. A short visit to Berlin must convince any unprejudiced and technically-trained engineer that a success of such vast importance has been attained which caused the famous Edison himself to remark that even he had considered such technical achievements impossible before he had seen them executed in Germany.

There have been, are, and will be always buyers in England who prefer English goods to those of foreign make, in spite of the higher price. The larger range of customers, however, is only too eager to make the matter of price their first consideration. It is my experience that people who consider it their business to advertise the advisability of employing British labour are the very first who buy for their own home circle foreign-made goods, if they can do so to advantage. The tests to which English and foreign incandescent lamps have been submitted must be considered, from a layman's point of view, utterly unfair, and from an electrical engineer's, downright ridiculous. To test incandescent lamps under admittedly favourable conditions for one lamp and under openly and deliberately unfavourable chosen circumstances for the other, can of course only result in a cheap and unreliable advertisement for the one kind of incandescent lamp, in whose favour the tests have been made, and cannot be regarded as either a reliable or scientifically-conducted test.

In the article on "Worthless Incandescent Lamps" the name of Mr. W. H. Preece, the electrician to the Post Office, has been cited, and there is certainly no more impartial and justly-disposed gentleman in the profession than he, and, in order to put the incandescent lamps of foreign manufacture on their proper merits, nothing could be more desirable than a prolonged and keenly-watched test of all the famous English and Continental lamps conducted under the personal superintendence of Mr. Preece. In order to obtain a fair test, quantities of at least 50 lamps of each make should be tested as regards accurate marking, economy, and life.

I am in the position to prove that a German firm manufacture 15,000 lamps a day, and that they even then cannot cope with their orders. This considerable output sold at a reasonable price proves the quality of the lamp in question, and also that a firm yielding such an enormous turn-out can be more scrupulous in assorting their lamps. I believe there is a good deal in the old English saying, "Call a spade a spade," and I only wish that all manufacturers would mark their goods as what they are—*i.e.*, English or foreign.—Yours, etc.

FAIR PLAY

DISTRIBUTION OF POWER.

SIR,—In your issue of January 17, page 83, under the heading of Messrs. E. Scott and Mountain, you refer to a large transmission of power plant, shipped to South America, of a capacity of about 160 h.p. It may interest your readers to know that at Messrs. Howard and Bullough, Limited, cotton machinery manufacturers, Globe Works, Accrington, we have a plant for the transmission of power of a capacity of about 450 h.p. This is comprised of two 80-unit and three 60-unit generating dynamos, one balancing transformer, and 51 motors, ranging from 10 h.p. to 30 h.p. This plant is working during the day at an output of about 375 h.p. for 14 hours, and during the night of nine hours at 50 h.p.; the plant is being rapidly extended, as the firm employ about 2,400 men, and no doubt the whole of the machinery will in time be driven by this power. The installation is on the three-wire system.—Yours, etc.,

G. W. SOMERVILLE.

WHAT, WHEN, AND WHERE.

Institution of Civil Engineers.

January 31, 8 p.m.—At Great George-street, Westminster, S.W. Students' meeting. "Ironfounding in Green Sand" and "Malleable Cast Iron," by F. A. Lart.

February 4, 8 p.m. Ordinary meeting. Adjourned discussion on "Recent Developments in Gas-Engines." Monthly ballot for members.

February 6, 4 30 a.m.—Special general meeting to consider a supplemental charter.

Institution of Junior Engineers.

January 31, 2.30 p.m.—Visit to Blackwall Tunnel Works.

February 7, 8 p.m.—Ordinary meeting. "Water Turbines," by F. W. Lowe (member).

Royal Institution of Great Britain.

January 31, 9 p.m.—At Albemarle-street, Piccadilly. "National Biography," by Sidney Lee.

February 7.—"Portrait Painting in its Historical Aspects," by the Hon. John Collier.

Society of Engineers.

February 3, 7.30 p.m —At 17, Victoria-street, Westminster. Inaugural address and presentation of premiums.

North-East Coast Institution of Engineers and Shipbuilders.

February 14, 7.30 p m.—At Lecture Hall of Literary and Philosophical Society, Newcastle-upon-Tyne. Ordinary meeting.

Society of Arts.

February 3, 8 p.m.—At John street, Adelphi. Cantor lecture, on "Alternate Current Transformers." Dr. J. A. Fleming, F.R.S., on "The Testing of Transformers." Lecture III.

February 5, 8 p.m.— Ordinary meeting. "The Mexican Drainage Canal," by Frederick Henry Cheesewright, M.Inst.C.E.

THE ARC LIGHT.*

BY PROF. SILVANUS P. THOMPSON, D SC, F R S

LECTURE III.

(Continued from page 101.)

Looking at this device of Staite's, and remembering that he also had a most beautiful wheelwork lamp in 1846, with a differential gear to turn a screw feed one way or the other, we see what a relatively crude thing it was that Foucault brought before the world in 1849. In Foucault's lamp the carbons were horizontal, and were made to approach one another by running on two little trucks, the position of the trucks being governed by cords running over a pulley, one being set by hand and the other one, which moved towards it, being allowed to advance by a cord which was wound up on wheelwork geared to a double train of wheels inside a box. That box had to be wound up by a key like ordinary clockwork, and, having a differential train of wheels, was governed by an automatic arrangement of an electromagnet, with an equaliser on the armature, and working against a spring. If the strength of the current were exactly right to balance that spring, an arm which went up vertically from the pivot stood in a perpendicular position. If the current was too strong, naturally the arm would be turned one way, and if the current were too weak the spring would bring it the other way. The position of this arm determined the question whether the train of wheels inside the box should turn to the right or to the left—whether, in fact, the carbon should be allowed to advance or retreat, or to move neither way if the current was exactly right. Foucault added a beautiful variable resistance, produced by two triangular and diverging pieces of metal dipping into water. As they were raised up near the surface, not only did they offer for conduction a diminished surface, but there was an increased distance between them. The whole contrivance constituted electrically an extremely beautiful arrangement, but mechanically was about as bad as could be conceived, the parts were so diffuse.

In developing this apparatus in later year, after the Serrin lamp had been introduced, Foucault was aided by the mechanical genius of Duboscq. In the well-known Foucault and Duboscq lamp of 1863 there was combined in good shape everything except the variable resistance that there was in the primitive arrangement: the carbons to be propelled towards one another, the differential train of wheels requiring to be wound up by a spring, and the lever which would let off one or other end of the train of wheels, and allow the carbons either to approach or separate, according to whether the current was too weak or too strong.

If one returns to the historical development of this subject the next lamp in order was devised by the architect Archereau, of Rouen, about 1848 or 1850. He had a solenoid with an iron core, acting against a little weight, as shown (Fig. 23). The weight would bring the carbons together, and the solenoid

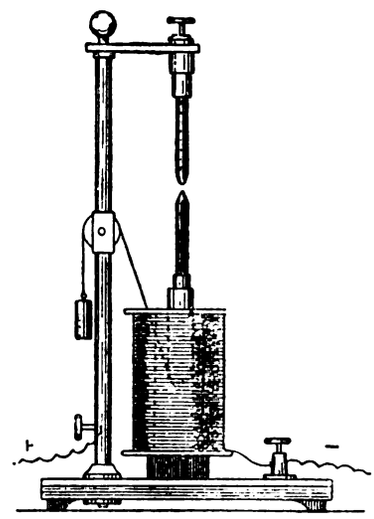

FIG. 23.

would part them. A lamp like this "pumps" very much; it moves up and down, and there is a great flickering in and out when starting, but when you once get it set it may feed very satisfactorily. This may be regarded as the forerunner of all the electric lamps; there is no clockwork; the action merely depends on the balance between gravity and the pull of the electromagnet.

Now let us go at once from these ancient things, which I have merely taken as typical of their kind, to lamps current in 1889. In the closing remarks of my lecture on that occasion I referred to two or three types of lamps as being characteristic of the respective countries, and the last sentence ran thus: "In conclusion, it may be pointed out that there exists a curious sort of family likeness between the several members of the three species of lamps most in use. The rack-train lamps, which may be considered as the prevailing Continental type, are for the most part, in their design and construction, clockmakers' lamps; they have a horological aspect. The clutch lamps, so universal in America, have a sort of sewing-machine look, the working parts being only finished where necessary for actual work, all else being left rough, or merely painted over. The clutch-wheel lamps favoured by British inventors have, in contrast to these, a look as though they had been designed and constructed by a trained engineer; they are essentially engineers' lamps."

That was justified by the comparison of the earlier rack and train clockwork lamps and the American type of clutch lamps, and two in particular of those which had been developed on British soil; and of those two lamps I reproduce the essential features here.

TWO MODERN BRITISH LAMPS.

The first lamp is the lamp which Mr. Crompton, in conjunction with Mr. Crabb, perfected about that time. The principle of its mechanism will be seen from Fig. 24. On the carbon-rod is cut a rack which drives a brake-wheel, or rather a pair

* Cantor lectures delivered before the Society of Arts.

Digitized by Google

of brake-wheels one behind the other on the same pinion. The arbor bearing is not fixed in the frame of the lamp, but passes through a short sleeve or jockey, which, when the wheel is free to turn, can slide up or down the carbon-rod, but is prevented from turning sideways by the guide-pin, *g*, above. Below the brake-wheels is a lever, L, pivoted at *o*, and attached by a link, H, to the core of the solenoid overhead. This lever carries a small table, *t*, and brake-piece, *b*, faced with phosphor bronze. When the lamp is out of action the free end of the lever is down, and the weight of the wheels and the carbon-holder bears down upon the table, *t*, by means of the pin, *p*, which projects from the jockey sleeve. In this position the wheels do not touch the brake-piece, *b*, and are free to rotate so that the carbon-rod is free and the carbons are together. When the current is turned on, the main current coil attracts its core, first drawing up the lever, which, turning on its pivot as it rises, brings the brake-piece against the rim of the brake-wheels and prevents them from rotating. Any further rise of the lever lifts the brake-wheel jockey and carbon-holder, thus striking the arc. As the arc burns away and the shunt coil comes into action, the lever descends slowly feeding the arc as required, and before it gets to the end of its tether the brake-wheels are released and feeding takes place by the release of the carbon-rod, the inertia of the wheels preventing any jerky motion.

Contrast that with the corresponding part of the well-known Brockie-Pell lamp. That lamp was already at that time a famous lamp, and has more than justified its existence since. It had also a brake-wheel, driven straight off the rack of the carbon-rod; and the brake that played against this wheel was a small projection, with a bit of leather or indiarubber round it, which was pressed in against the inner side of the rim of the wheel. There was loosely pivoted to the same centre a large

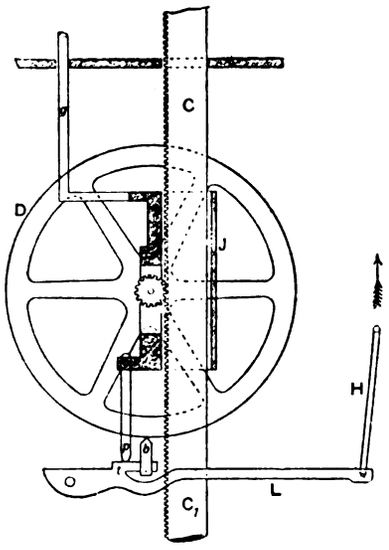

FIG. 24.

sector piece, which, as a matter of fact, was weighted, to make it heavy; and upon that sector piece there was pivoted an auxiliary lever, which was worked by a see-saw overhead, the see-saw itself being operated by two cores, which ascended into a solenoid. One core, in a main circuit solenoid, pulled up, and the other core, in a shunt solenoid, opposed it. Suppose the main current is very strong at the moment of striking the arc, this core is pulled violently up. The first thing that happens, then, is that the auxiliary lever is caught at its tail by a fixed piece, and turns round on its pivot, raising the weight, and clamping the little brake-piece against the interior part of the wheel, and then, if there is any further rise, they rise solidly together—that is to say, the auxiliary lever, the heavy sector, and the wheel all rise together about a centre, and raise the carbon, and strike the arc; in fact, one has a kind of internal toggle brake against the rim of the brake-wheel.

About this time Mr. Brockie modified his mechanism, and put the little brake outside instead of inside, and he has made various detailed improvements since, and has brought out several patterns of lamps. Here is one of the forms of brake-wheels now employed in one of the many lamps made by Messrs. Johnson and Phillips, under Mr. Brockie's superintendence. In this case the upper and lower carbons are carried by flexible cords, which pass over two pulleys rigidly fastened together, but electrically insulated at the back of the wheel. The wheel in this case is put at the top of the mechanism of the lamp, instead of being at the bottom. The electrical action has to perform the following function. When it attempts to raise the long lever which is sprung across the middle, the little auxiliary lever causes the brake-piece to bite against the inside; they are gripped together tight, and the whole thing has to go round together. When the long lever is let down, however, owing to the small auxiliary lever descending with its tail upon a fixed point, the grip is released, the wheel can turn, and the arc can feed little by little as the motion allows the wheel to turn. To strike the arc, it has to turn a little backwards; to feed, it must be allowed to creep forward as wanted by imperceptible degrees. A similar sort of arrangement of a clutch against the moving part Mr. Brockie has used in another pattern of lamp, which is favoured by the Post Office, wherein there is no brake-wheel; the clutch works in that case on a perpendicular rod.

I believe that all the inventors of arc lamps go through a species of evolution themselves. Take almost any one of the many names in arc lamp work—take Mr. Brockie as an example, or Mr. Crompton, or almost any other—and you will find that the inventor is never satisfied with his first performance. He is impelled to go on, and the record of almost any one of these men will show that they have tried successively various types, and have gone on, sometimes on one line, sometimes on another, developing and perfecting, until they got something very near perfection indeed. The brake that Mr. Brockie has in this lamp is, I suppose, about as near perfection for minute feeding as any brake applied to the rim of a wheel could possibly be. I alluded just now to one feature of the Brockie-Pell lamp—the use of the see-saw piece. This see-saw is a lever operated by two iron cores going up into solenoids, one of which is included in the main circuit, while the other is joined as a shunt.

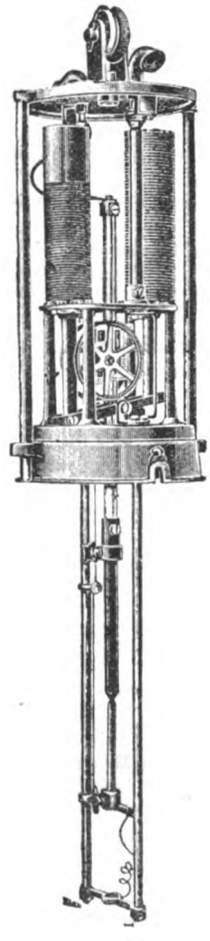

FIG. 25.

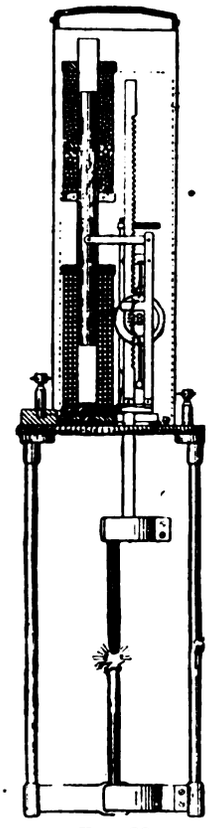

FIG. 26.

It was no new thing in 1889 to have a differential motion in a lamp. The first one was about 1855. The well-known Brush arc lamp had differential winding on the electro-magnet, the series and shunt coils working against one another. Even earlier than that Siemens had a differential solenoid working at the two ends of a straight core—the series coil trying to pull the core down, the shunt coil trying to pull the core up; but so far as I am aware, the special advantage of this see-saw arrangement with a shunt at one end and a series at the other was in 1889 not generally recognised. True, it existed in the Thomson-Houston lamp and in the Brockie-Pell, but scarcely in any other lamps. Now the real advantage of using a see-saw over a differential winding or over a differential plunger is this: that in this case when both the opposing parts are fully in action, when the main circuit coil only is pulling hard at *a*, the shunt coil is pulling hard at *b*, the lever is subjected to considerable forces, nearly balancing one another, and any small difference arising from any change of the current in either coil would be quite sufficient to produce the required movement action. Even if there were friction in the parts the movement will occur with certainty, because the forces balancing one another are comparatively large mechanical forces. Whereas in the American plan of using a differential winding, when the two coils have their magnetising effect nearly in balance, the mag-

Digitized by Google

netism is almost zero, and, therefore, the forces are almost zero; and hence the mechanical effect is comparatively at a disadvantage in contending with any tendency of the mechanism to stick. Friction plays a much more important part in determining whether the feeding apparatus is or is not to act in those lamps where you do not utilise to the full the mechanical value of both the currents—that in the main circuit coil and that in the shunt coil. Here, in the see-saw, they are utilised to the full. It is quite remarkable how the see-saw mechanism has, since 1889, grown into favour with other inventors. Kent's lamp, for instance, has a see-saw. At one end there is a shunt electromagnet, and at the other a series electromagnet. The see-saw is between the two, so that the mechanical pull of both coils is utilised to the greatest extent.

In Fig. 25 we have the Crompton-Pochin lamp—of which the brake-wheel part is practically identical with the Crompton-Crabb brake-wheel (Fig. 24); but instead of having a long solenoid, with an iron core, to be pulled by a lever, there is a series coil and a shunt coil at the top of the lever working the see-saw. One might point to other lamps of modern type, in which the same see-saw arrangement has survived the less effective forms. In the latest Crompton-Pochin lamp the see-saw operates a hand brake. The lamp hanging before you is the form of lamp now produced by the Brush Company, under the name of the Brush-Vienna lamp. I belive the greater part of its mechanism is due to Mr. Kremenetsky, of Vienna. It has a series coil, and a shunt coil, and a see-saw working between them. As in many other Continental lamps in which clockwork or wheelwork is still employed, the operation of the electromagnets of the lamp is to rock over the clockwork bodily, both for striking the arc and for determining whether the feed shall occur or not. You will find that in a very large number of lamps that have developed of late years, the question whether the train of mechanism shall or shall not be permitted to turn is made to depend on the position of the wheelwork as a whole, and the wheelwork is turned round on some convenient axis. One's mind travels back to 1882, at the time of the Crystal Palace exhibition, when there was a lamp with tilting clockwork in it, shown by Mr. Brockie; a lamp which was never extensively employed, because Mr. Brockie went on to higher things.

Development of Siemens's Lamps.

We have here, amongst other pictures, a whole series of German lamps developed by the house of Siemens, illustrating the progress of invention so far as that firm are concerned.

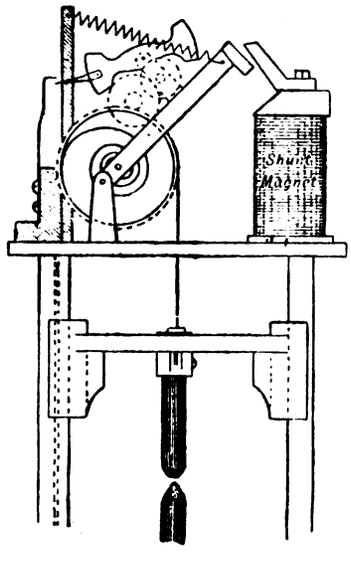

Fig. 27.

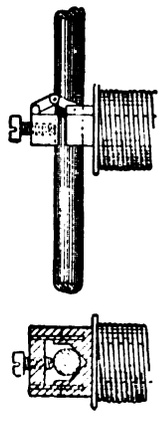

Fig. 28.

In one of these (Fig. 26) the differential principle is introduced. The upper carbon is supported by a rod on which teeth are cut, which engage with a small pinion mounted on a frame. The pinion is only allowed to turn by driving a pendulum by means of an escapement, so that the feed will go on slowly but continuously so long as the series coil is not in action. When the current is turned on, the frame containing the escapement and carbon-rod is lifted, striking the arc, and the top of the pendulum becomes fixed in a little nick. If the arc burns too long the shunt coil brings down the frame, giving immediate relief, and when the frame has moved a little distance the pendulum is released, which, in slowly allowing the escapement to operate, gives permanent relief by feeding the carbon forward.

Now we come to the "flat-topped" lamp. It was a great thing to get rid of these very long carbon-rods with their racks, as they took up so much vertical space. In this lamp the carbons were simply clamped to a cross-piece, top and bottom. The top cross-piece was gradually screwed down by an arrangement with a gear vibrating, almost like an electric bell mechanism, which took up a wheel tooth by tooth, and so drove the screw feed down. This was the precursor of a much more important lamp that the firm of Siemens has been putting out for the last half-dozen years.

In Siemens's "band lamp" (shown in Fig. 27) we see that the carbon is clamped into a heavy holder; there is no long carbon-rod, the carbon is suspended on a flexible band or cord of woven copper, that goes over a drum, inside which there is a spring. The weight must be so heavy that it will uncoil that spring, and when you lift it up to put in a new carbon the spring coils itself up again. This mechanism has two toothed wheels to multiply motion, and then an escapement (with a little piece sticking out at the end of it), and the whole is carried on a frame, which can be tilted. This, again, brings us back to the tilting wheelwork which Mr. Brockie had in 1882. In the present case the only magnet is a shunt-wound electromagnet working against a spring. Supposing there is no current supplied to the lamp, that magnet does not pull; the spring pulls back the frame, and the clockwork is locked. When the lamp is put on a circuit, there is no way through it except through the shunt, the magnet will therefore pull the armature forward, which motion will lower the upper carbon a little towards the lower carbon, and make them touch; or, if they do not touch, it releases the escapement, and that will work, letting the upper carbon descend until they touch. The moment the main circuit is thus completed, there will be less current going round the shunt; the spring will therefore rise, and the clockwork will be locked until such time as it is necessary for feeding to occur.

A Belgian lamp, described in 1889, illustrates this feature of the rack and wheel work turning on a pivot, which is so often found in Continental lamps.

The exclusive use of a shunt coil without any main circuit coil, though it was not well known, is a feature which has existed a long time. There was the Lontin lamp of 1877, a variety of the Serrin. This is the first case of a lamp working only by a shunt coil. The Serrin had a series coil to pull down a jointed parallelogram to prevent the feed occurring. In the case of the Lontin lamp the jointed parallelogram was raised by the operation of the shunt coil, and the feeding mechanism released, which otherwise was locked when the frame descended by its own weight. Many lamps with shunt coil only are now in use.

Improvements in Clutch Lamps.

There are a few other types which have developed since 1889, amongst them the clutch lamps. The next few diagrams relate to clutches that have been developed since that time. The first (Fig. 28) is that of the Helios Company. Here the actual carbon comes down in front of the pole of an electromagnet, which has a deep groove in it against which the carbon slides. A small iron armature with an adjusting screw is made to grip against that carbon rod with a sort of knee-joint above, and holds the carbon rod as long as that electromagnet does its duty, but as soon as the electromagnet ceases to pull, as can be arranged by differential winding, the clutch releases the carbon rod, lets it slide a little bit, and then catches it again. This necessitates

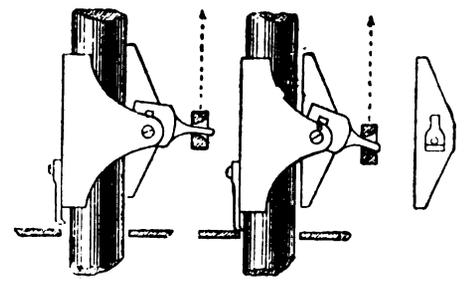

Fig. 29.

an independent arrangement for striking, but it is interesting as a form of clutch.

Then we come to the improvement in 1893 of the Brush lamp by Mr. Adams, one of the engineers of the Brush Company in Cleveland. In the old Brush the clutch was a simple ring or washer, which gripped the carbon rod and raised it. That was replaced by Mr. Adams by a nipping clutch (Fig. 29) with a separate toggle-joint arrangement, which in one position pulls the clutch-piece away from the carbon rod and allows it to slip, and in the other position nips it against the rod and holds it up. The question whether the brake-piece is to be allowed to advance towards the rod and hold it, or to retreat from it, depends upon the position of the arm which comes down from the solenoid above, and depends on the larger portion of the clutch being allowed to come down into contact with the floor of the mechanism of the lamp. I have here for exhibition two lamps of the Brush Company's manufacture. One is an example of the Brush-Adams lamp, the other a Brush alternating-current

Digitized by Google

lamp, with laminated iron cores for the solenoids, and having the old kind of clutch.

HELIOS ARC LAMP.

Another lamp here, which has tilting clockwork, is kindly sent me by the Helios Company. We have here the feature of the two coils, series and shunt, and a kind of see-saw. The operation of that see-saw is, however, to tilt a train of wheels, and the question whether those wheels shall be allowed to turn round or not depends on the amount the clockwork is tilted over, so that that combines the Continental feature now so common of the see-saw. This also is an alternate-current lamp; but it has the novel feature of an enamelled iron reflector set just above the end of the upper carbon, and surrounding it, so as to throw downwards (as shown in Fig. 12) the light that otherwise would be projected obliquely upwards. A quite small mirror, fastened on a bridge between the rods that form the frame of the lamp, suffices for this purpose.

THE PLANET COMPANY'S ARC LAMPS.

Another type of lamp has been developed by the Planet Electrical Engineering Company, of London. A motor is made to turn one way or the other, according as the voltage of the lamp exceeds or falls short of the prescribed amount, and the motor drives a feeding-screw. I have been using a Planet lamp in these lectures when illustrating the Trotter phenomenon. It is one of the compact little lamps which the Planet Company is now making specially for projector work, with a motor very neatly packed away at the bottom.

(To be continued.)

ALTERNATE-CURRENT TRANSFORMERS.

BY DR. J. A. FLEMING, F.R.S.

The second Cantor lecture of the series of four by Dr. Fleming on the above subject was delivered on Monday last. After briefly referring to his last lecture, Dr. Fleming showed a most interesting water analogy to explain the action in transformers. Using a U-tube, with limbs of different diameter, half filled with coloured water, he imparted a varying pressure on the water in one limb, causing it to rise and fall. The motion of the water in the other limb then had a corresponding movement, but the height of the waves in each tube was, of course, proportional to the areas of the tubes. Also, the water was at its highest level in one tube when the water in the other was at its lowest. This corresponded to the 180deg. difference of phase between the primary and secondary currents in a transformer. Dr. Fleming then proceeded to discuss the construction and manufacture of transformers. He stated that every transformer had three fundamental organs—*i.e.*, the iron circuit and the primary and secondary copper windings. Dealing with the lamination of the iron circuit, he stated that it had been proved that there was no advantage in using plates thinner than one hundredth of an inch, and also that unless they had plates thinner than 1-25th of an inch it was useless to laminate at all.

He then proceeded to discuss the data connected with hysteresis and eddy currents in the iron cores, and gave the following formulæ. The eddy-current loss, E, per cubic centimetre of iron in watts, where t = the thickness of the iron plates in mils, n = the frequency, and B = the induction in C.G.S. lines per square centimetre, is obtained as follows:

$$E = \frac{(t\,n\,B)^2}{10^8}.$$

Again, E′ the loss in eddy current per pound of iron is given by

$$E' = 1{\cdot}4 \times 10^6 \frac{(t'\,n\,B')^2}{10^8},$$

where t' = thickness of plates in inches,
and B′ = the C.G.S. lines per square inch.

The formulæ for hysteresis loss were as follow:

$$H = \frac{{\cdot}0032\,n\,B^{1{\cdot}55}}{10^7},$$

and

$$H' = \frac{{\cdot}88\,n\,(B')^{1{\cdot}55}}{10^9},$$

where H = hysteresis loss per cubic centimetre;
H′ = ,, ,, ,, pound;
n = the frequency;
B = the induction in C.G.S. lines per square centimetre;
B′ = the induction in C G.S. lines per square inch.

The lecturer, to show the accuracy of these formulæ, gave a list of a series of old Ferranti transformers, comparing the observed and calculated iron losses. The two compared fairly well in some cases, but it was not pointed out that the constant in the hysteresis formulæ had to be varied in order that they might do so, nor was it mentioned at what temperature the eddy-current formulæ were correct.

That such corrections are needed might perhaps be inferred when it was afterwards stated that no iron should be accepted which had a higher loss than ⅓ watt per pound at 100 ∽ and B = 2,500. A curve was then shown on the screen which was stated to give the variation of hysteresis and eddy currents with the thickness of plate. The hysteresis curve showed an increased loss of 100 per cent. over the range of thickness, but the new fact (?) that the hysteresis varies with the thickness of plate was not referred to. The possibility of making a transformer with no iron loss was most interestingly discussed, and then a series of exhibits of commercial transformers ended a most practical lecture.

INSTITUTION OF ELECTRICAL ENGINEERS.

The following gives more fully than it was possible to do in our last issue the concluding speeches in the discussion on the wiring question at the Institution of Electrical Engineers on the evening of January 23.

Mr. W. Langdon, who followed Major-General Webber, said that he was not going to join in any general condemnation of wooden casing It had been of great purpose in extending the use of the electric light. It was cheap, and where it was carefully employed it was still calculated to be of considerable service. Of course, metal tubing was safer than wooden casing, but where buildings were already erected it would be inconvenient and unsightly to wire with tubing. Wood casing was cheap, and there was no law to compel the wiring contractor to use any one particular method, and therefore the cheapest would be employed. The practice, however, of fastening the casing with metal screws or nails between the two grooves carrying the wires was not a good one since, with impaired insulation, these would greatly assist in making a short-circuit between the two wires. Screws at the sides were therefore better. The rule had been adopted by the Midland Railway Company that where wires were out of sight iron tubing should be employed, but wooden casing should be used where it could be easily seen. He had seen samples of wiring work carried out by firms of good reputation where many of the joints were dry joints, and were found to be insulated with nothing better than adhesive tape. If they got that sort of thing when a firm was not carrying out a contract job, what might they expect when they had a contractor doing work inside a fixed price? Mr. Mavor had thrown out the suggestion that the fire insurance offices should combine to employ a competent man in every town to inspect installations, but there were many towns in which it would be difficult to secure the services of such a man and properly paying him. It would, he thought, be better for the supply companies to establish a system of competent inspection of installations while they were in progress, since, though the supply companies had power to reject any installation that was found defective, they had in many cases nothing to go upon but an insulation test and a cursory inspection

Mr. Donovan spoke of the necessity of inculcating a careful attention to detail on all who were engaged in wiring work.

Mr. Antill thought it had been clearly brought out by the two papers and the discussion that no one system was applicable to all cases, and that the contractor must vary his system according to the circumstances. As to open work, the most prominent example of that was at the British Museum, where the wires were supported on porcelain insulators. This had given the most perfect satisfaction since it was first put up. He did not think that Mr. Bathurst had used the word "accessibility" quite fairly in applying it to wires in tubes that could only be inspected by drawing out. No one would be in the least likely to inspect wires by drawing out until after a fault had occurred. He (the speaker) considered that "accessibility" implied that the facility for inspection was such that an incipient fault could readily be discovered. Again, the curve published by Mr. Mavor did not accurately indicate the employment of the wiring men throughout the year. What it indicated was merely the number of lamps connected on to the mains each month in Glasgow. The work of a large installation might be spread over several months, but the result would be all placed to the credit of the month in which it was finished. The practice of insisting on a high-insulation test for cables defeated its own object; for a high-resistance test could be obtained by other means than quality and thickness of the insulating covering. In conclusion, Mr Antill called attention to the similarity of the concentric cable to the concentric leads employed in the single-wiring system which was worked out by Mr. John Raworth for ship-lighting many years ago.

Mr. Campbell Swinton said that experience had shown that Mr. Mavor's system was not at all unsuited for highly-decorated houses. He had been convinced of that by an example of it shown to him at Dumbarton. But there was one practical difficulty in the way of the adoption of the system. It meant that the contractor must maintain two separate staffs of workmen. If a contractor was going to use wood casing his men must be of the house-carpenter class, while if the concentric system were adopted the men wanted would be more like plumbers. The concentric system was at present only applicable to alternating-current systems where there was a separate transformer or to isolated plant installa-

Digitized by Google

tions, and was not applicable with continuous-current systems where the supply was taken from the public mains. He had lately had to report on the lighting of a building in Edinburgh, and it was in doubt whether it would be better to take current for the Corporation mains or to have a separate generating plant. If the former course was adopted, the concentric cable system, though eminently adapted to the case, must be ruled out, since the outer conductor could not, under the regulations, be earthed. He had recently made some experiments to see what current could actually be carried by certain wires of small size. Thus a $^{3}/_{22}$ vulcanised wire cased in the ordinary wood covering took a current of 26 amperes for half an hour with a rise of only 107deg. F. The current density worked out at 13,700 amperes per square inch. Again, a $^{3}/_{25}$ wire in the same condition stood a current of 26 amperes for one hour, the rise of temperature being 242deg. F The temperature had in that time become constant. The density in this case was 28 900 amperes per square inch. He had also passed 10 amperes through an ordinary flexible wire without damage. He did not recommend this high current, but gave the facts to show how difficult it was to state what current a wire would safely carry.

Mr. C. S. Corlett said that he was at one time sceptical about the advantages of the system of concentric wiring, partly owing to the difficulty of obtaining workmen skilled in the erection of it. He had, however, recently equipped a large cotton mill with some 600 lights on Mr. Mavor's system, and had found it cheaper than he had expected. The total cost had worked out at 17s. per lamp. As regarded the question of increased voltage raised by Mr. Geipel, he had had an installation at 200 volts working in a colliery and had found the lamps quite satisfactory.

Before adjourning the discussion, **Sir David Salomons** referred to a case in the early days of electric work in which the inspector, after having the term "cut out" explained to him, went away quite contented that the work was in order.

The following letter has been addressed to all members and associates of the Institution of Electrical Engineers:

"The Council of the Institution of Electrical Engineers have resolved 'that steps should be taken to render available for purposes of national defence the technical skill of electrical engineers, and that a committee be appointed with instructions to take such steps as it thinks fit to attain that end,' and have appointed the following gentlemen as members of the committee: The President (Dr. J. Hopkinson, M.A., F.R.S), Sir Frederick Abel, Bart., K.C.B., D.C.L., F.R.S, Mr. R. E. Crompton, and Major-General C. E. Webber, C.B. (past-presidents), Mr H Edmunds, Mr. R. S. Erskine, and Mr. A. E. Mavor, to whom have since been added Sir Benjamin Baker, K.C.M.G., LL.D., F.R.S., and Prof. A. B. W. Kennedy, LL.D., F.R.S.

"It hardly seems necessary to point out in how many ways a practical knowledge of electrical science could be made useful in time of war. Everyone knows that the acquiring of a knowledge of this science is a not unimportant part of the training of military engineers. This knowledge electrical engineers already possess, but they have at present no opportunity in time of peace of preparing for the practical application of that knowledge for the purposes of war.

"In order to carry out their instructions, it is necessary for this committee to ascertain what support it may expect from members of the Institution and others engaged in electrical industries. Hence the present communication and the following questions are addressed to you.

"One of the objects of this committee is to ascertain if there are candidates amongst the electrical engineers to fill the vacancies in the list of officers.

"In order to enable you to judge of the matter it may be well shortly to state the existing conditions of service in the various corps, particularly of military engineers, which now form part of the reserve forces of this country.

"These are divided between militia and volunteers, and are described, with a list of the names of the commissioned officers, in the monthly army list, which also gives the various places where those corps are located.

"With one exception (the corps of railway managers and engineers) they are formed in battalions and companies, having the usual military organisation.

"The volunteer force is composed of the following arms: light horse, artillery, engineers (fortress and submarine mining), rifles, medical staff corps.

"The corps of engineers (submarine mining) is perhaps the arm to which electrical knowledge is most extensively applied at the present time. There exist divisions located on the Clyde, Forth, Mersey, Severn, Tay, Tees, and Tyne. The divisions are in general highly efficient, but there is a lack of officers. The preliminary training of officers requires in all about six weeks' work, which may be spread over two years. The duties of officers include attendance in camp at the headquarters of their division for not less than eight or more than 15 days, and at 48 drills, a full day's work counting as six drills. The advantages are—very interesting and healthful work, and an allowance of 10s. a day employed in training or in camp.

"In the other arms there is much less need for attendance at a camp which may be remote from the home of the volunteer. The corps of fortress engineers is recommended to those who cannot afford time for prolonged attendance at a distance from their residence The following is a list of the existing regiments of fortress engineers: 1st Middlesex, 1st Lanarkshire, Edinburgh City, 1st Lancashire, 1st Newcastle on-Tyne, Yorkshire (West Riding), 1st (Sheffield), 2nd (Leeds), Gloucestershire 1st (Cheltenham), Cheshire 1st (Birkenhead), 2nd (Railway) Crewe. Denbigh, Tower Hamlets 2nd (East London), Cumberland, Surrey, Hampshire 1st (Portsmouth), Glamorgan, Essex, Devonshire and Somerset 1st(Exeter), London 1st (North), Flintshire 1st(Buckley), Northamptonshire 1st (Peterborough), Durham 1st (Jarrow), Aberdeenshire 1st.

"In the case of the militia longer attendance is required in camp than in the case of the volunteers—for example, the militia submarine miners have annually 55 days in camp, and during the first year four months' training. Of this arm there are divisions located at Portsmouth, the Needles, Plymouth, the Thames, the Medway, Harwich, Milford Haven, Western (Severn), the Humber, and Falmouth.

"*Special Corps.*—The modern development of the uses of electricity is certain to lead to its extended application in war time. It is proposed, therefore, subject to the approval of the War Office, to organise and train a special corps of electrical engineers, whose duties will be defined at a later date.

"It will further be the object of the committee to ascertain if the military authorities will regard favourably the enrolment of electrical engineers on some such basis as was followed in the case of the railway engineers, by which the services of many who cannot afford the time for organised training, but who are willing to seek certificates of efficiency suitable to their attainments, can be promptly utilised by the War Office in case of national emergency.

"This statement will, we believe, enable you to judge which branch of the force you could most usefully join. Will you kindly reply to the questions put on the accompanying form? Later, if you are disposed to take an active part in the movement, you may expect to hear from us further.

"If you occupy a leading position, superintending the work of artisans, will you also ascertain and inform the committee how many of these in your employment would be willing to join such a special corps as has been suggested.—On behalf of the committee,

"J. HOPKINSON, President."

The following are the questions put on the accompanying form referred to:

"1. Are you willing as an electrical engineer to register your name as ready to undergo training, and to serve in case of urgent need?

"2 Are you willing to begin training at an early date, and to accept a commission in the reserve forces if obtainable, or to join the ranks of a volunteer corps?

"3. Which branch of the reserve forces do you prefer?

"4 Would you prefer to join a special corps of electrical engineers (*a*) as an officer, (*b*) in the ranks?

"5. Are you at present a member of any volunteer corps?"

THE PHYSICAL SOCIETY.

A meeting of this society was held last Friday evening, Captain Abney, the president, being in the chair.

Mr. Campbell Swinton exhibited some photographs which he had taken by Prof. Röntgen's method. These included several of metal objects inside wooden and cardboard boxes, and a very clear and sharp photograph of the bones of the hand.

Mr. E. Scott showed some geometrical instruments invented by himself and Signor Monticolo. The instrument designed by Signor Monticolo was intended for drawing arcs of circles of such large radius that compasses cannot be employed It can be used to trace arcs of circles of which the radii vary from 50cm to infinity. The second instrument exhibited was a modified form of hatchet planimeter, which Mr. Scott has devised with a view of avoiding some of the defects of the ordinary form of instrument. Thus, to avoid the cutting of the paper, which occurs when the knife-edge is sharp and the side slip, which occurs when the knife-edge is blunt, the author uses a wheel with a sharp edge. To avoid the inclination of the instrument to one side, which may easily occur with the ordinary form, a flat celluloid plate, with a dot at the centre, is used as the "tracing point," this plate being kept pressed flat on the surface of the paper. A small wheel with a recording disc is attached, and may be used to measure the distance between the first and last position of the knife-edge. Mr. Scott also described a form of planimeter which he had invented, and in which the disc and cylinder movement is used to perform the integration.

Mr. C. V. Boys said that an instrument designed by Mr. Clarkson had been exhibited before the Royal Society which was capable of drawing arcs of circles of large radius. This instrument only drew an approximation to a circle, but the approximation was so close that it nowhere was more than the thickness of a thin ink line away from the truth. It would be interesting to hear from the author whether Signor Monticolo's instrument drew a rigorously exact circle or not. The upright position of the hatchet planimeter might be secured by using two wheels in place of one. The planimeter described was really a modified form of one he (Mr. Boys) had described before the society in 1881.

Mr. Blakesley gave a short geometrical proof showing that the curve traced by Signor Monticolo's instrument was rigorously an arc of a circle Mr. Blakesley also drew attention to the fact that the instrument in its present form cannot be used to trace the arc on both sides of the zero line.

Dr. C. V. Burton described an idea for an instrument for drawing circular arcs which had occurred to him, depending on

Digitized by Google

the use of two wheels of different radii, connected by an axle carrying a tracing point

In the absen e of the author, Prof. J. D. Everett's paper on "**Resultant Tones**" was read by **Dr. Burton.**

COMPANIES' MEETINGS AND REPORTS.

CITY AND SOUTH LONDON RAILWAY.

The ordinary half-yearly general meeting of this Company was held on Tuesday at Winchester House Old Broad-street, E C., Mr. C. G Mott, the chairman of the Company, presiding.

The **Chairman**, in moving the adoption of the report and accounts, a copy of which appeared in our last issue, said the Company had carried during the half year over 3,000 000 passengers with perfect safety and great punctuality There had, nevertheless, been a decrease of 103,000 in the number of people carried, as compared with the corresponding half of 1894 but an increase compared with the June half of last year of about 60,000. The decrease was explained by the fact that they increased the fares about a year ago in order to diminish overcrowding; it had that effect, but also decreased their receipts. Then, during the first three months of the past half year there was very hot weather, and that always acted prejudicially on the traffic on the line As a result of the decrease, they had reconsidered the question of the fares and had lowered them at one of the stations to their old level. The result was that they immediately obtained an increased number of passengers, and this compensated them for the loss they had in the previous quarter, but left them with a decrease in receipts of £50. On the other hand their season ticket holders had slightly increased, while the receipts from that source had been augmented by £290 Their object in increasing their fares was to lessen the overcrowding in the early morning trains but, unfortunately, as had been seen, this decreased their revenue. They had partially recovered that loss and he hoped in the current half-year they would show a decided increase, both in passengers and receipts. To deal with the overcrowding they had made some alterations at King William-street Station by which they could have two trains in at once, as at Stockwell which obviated the necessity of waiting for trains, and would also allow them to run some additional trains. Hitherto they had unfortunately had to turn away a large number of passengers and to delay those who travelled. This injured their traffic very considerably, because people coming to the City wanted to be certain of arriving at a given time almost to the minute, and if they could not depend upon the electric railway for that they either arranged to travel by other means or even ceased to reside in their district. The directors had now done everything they could with their present line to meet the traffic, and to provide accommodation for it and they hoped these new arrangements would enable them to keep pace as far as possible with the demands upon them for another twelvemonth. It was only, however, a temporary provision, and they felt that the time had now arrived when they could no longer delay the additional accommodation which they proposed to provide to enable them to deal with the rapidly-increasing traffic on their system. They had been very cautious about not going on with this work earlier, but he was afraid they had delayed the matter too long. It was evident that there was no time to be lost now, and they were asking the authority of the shareholders to proceed at once with their extension. In their report they therefore asked for authority to proceed with that portion of the Islington extension lying between its connection with the existing line and Finsbury pavement. After referring to the details of the report and accounts, the Chairman said the net result was that they were better for the half-year by £673, which was nearly equal to an increased dividend of ¼ per cent. They did not, however intend to declare that extra dividend, as the money was wanted to replace the balance brought forward which had been drawn upon last year to make up the dividend. They had not only restored that balance to its old figure, but had improved it. Their working expenses had been 59·2 per cent., as against 60 9 per cent. for the corresponding half-year, or omitting the expense of the lifts 51½ per cent., compared with 52 per cent. in the corresponding period In reference to their extension, satisfactory arrangements had been made as regarded the sites of the stations up to Finsbury-pavement, and they felt pretty certain that the line could be completed for the amount stated last year as the estimated cost—namely, £280 000. It was not possible to fix the amount exactly, but if they did it for that sum they would, considering where it was situated, get a very cheap line. They did not propose at present to proceed with the extension of the line beyond Finsbury-pavement to the Angel at Islington, and as the powers of the Company for the compulsory purchase of lands in connection with the Act of 1893 would expire in August next, application was being made to Parliament for a further extension of that time. In the same Bill powers were sought for the acquisition of a site for a temporary shaft in the Borough High-street, with a view of saving expense in the construction of the junction of the new extension with the existing tunnels.

Mr. Sampson Hanbury seconded the adoption of the report, and it was carried unanimously.

Formal resolutions authorising the payment of a 5 per cent. dividend on the preference, and a 1½ per cent. dividend on the ordinary stock, were passed, and the retiring directors and auditor were re-elected.

Notice having been given for an extraordinary general meeting, the **Chairman** then proposed a resolution authorising the additional capital sanctioned by the Act of 1893 by the creation of 55,000 new ordinary shares of £10 each and 20,000 preference shares of £10 each, bearing 5 per cent. interest. The Chairman said the Board had most carefully considered what was the most economical way of raising money for the extension, and had concluded that it would not be desirable to obtain it by ordinary shares at their present price. The Company's preference shares were selling at 50 per cent. premium, so that by issuing 5 per cent. preference shares they would be obtaining the money at 3½ per cent. They did not intend to interfere with the dividend on the ordinary share capital, and the preference shares would be issued in such a way that the dividend on them would not be payable until the line had been opened and in operation for some time.

Mr Barclay Heward seconded the motion.

Mr Thomas Hanbury strongly opposed the projected extension, and, in the course of a long speech, contended that it was really a new undertaking, and therefore ought to be constructed out of ordinary capital. He strongly doubted whether the extension would realise the expectations of the Board, and was certain that, as regards the traffic from the London Bridge Station, passengers would go over the bridge in an omnibus rather than under it in the Company's train, as there would be no saving of time. The line was called an extension but it was practically the beginning of a new line with a terminus in a new direction. The London, Brighton and South Coast Company were the proper persons to make such a line as was now proposed, but they had made no movement and given the Company no encouragement. Moreover, he did not think the Company ought to incur the odium attached to removing the church of St. Mary Woolnoth. He considered it unwise and unjust to place £10 000 per annum required for the preference dividend in front of £7,500 per annum, the only income at present available for the ordinary shareholders, and he therefore proposed that the issue of £200 000 of 5 per cent preference shares be not authorised

Mr. J T. Middleton seconded the amendment.

Mr. Drake supported the original resolution on the ground that the matter had already been decided, and several questions followed from shareholders as to the terms and time of the new issue.

The **Chairman**, in reply stated that he could not go into the question of the desirability of constructing the extension, as that had been approved by the meeting when the report was passed. The point before them was simply the best mode of raising the money. They had fully considered this matter, and they were convinced that it would be most undesirable in the interests of the Company to obtain the capital by means of a separate undertaking. They were going to make a station for the Brighton and South-Eastern Companies' traffic at London Bridge, and they would have an underground connection up to the platform of the Brighton Company. He had not the least doubt that they would get a very large traffic there. If he had any doubt it would be as to their capacity for dealing with the traffic coming in such masses in the morning As to St Mary Woolnoth, it was only within the last two or three days that any opposition had been expressed to their taking the church. The opposition came from the City Church Preservation Society, and not from the ecclesiastical authorities. The bishop and the incumbent were satisfied, and the money paid for the site would be used for constructing churches in poor and populous districts, where they were more needed. It was, however, too late to discuss this question now, for all their arrangements were completed. The matter had been before the public for three or four years, and they had no objection made until now. There was practically no other site available The matter was discussed before the Parliamentary Committee of the Bill, and it was too late to reopen it.

On the amendment being put only three or four hands were held up for it, and it was accordingly lost, and the original motion carried.

The meeting was then made special for the approval of the Company's Bill in Parliament extending the time for purchasing the land for the purposes of their Act of 1893 and for completing the underground railway and works thereby authorised, and the formal resolution having been carried unanimously, the meeting ended with the usual votes of thanks.

EASTERN TELEGRAPH COMPANY

The forty-seventh half-yearly ordinary general meeting of the Eastern Telegraph Company, Limited, was held at Winchester House on January 23. The **Marquis of Tweeddale** (vice chairman of the board of directors) presided, in the absence of the chairman (Sir John Pender, M.P.) through indisposition, and moved the adoption of the directors' report, with accounts, for the six months ended with September last. The past half-year, he said, was one of the most satisfactory the Company had ever experienced. It was distinguished by two very satisfactory features. One was a large increase in the receipts, and the other was a decrease in the expenses. This was fully borne out by the figures. The revenue for the half-year was £409,779, being an increase of £47,223 compared with the corresponding period of 1894. An examination of the message receipts from various sources showed a satisfactory increase in nearly all classes of traffic, but the principal increase was in the traffic with West Australia and South Africa, which was owing to the activity in the gold mining markets. With respect to the traffic with South Africa, it was satisfactory to note that, notwithstanding the large reductions made in the tariff, an increase had taken place on the value of the traffic

Digitized by Google

at the former rates, but, as this was entirely owing to special circumstances, they could hardly count upon its being maintained. The total ordinary expenses for the half-year ended September 30 had been £96,704, or a decrease of £829 compared with those of the corresponding period of the previous year. So long as the Company could show an increase of revenue and at the same time keep down the ordinary expenses within reasonable limits the shareholders would agree that the position would be a very satisfactory one, and this was borne out by the fact he had stated, that, notwithstanding a considerable increase of the revenue for the past half-year, the ordinary expenses showed a substantial decrease; but, although every care was exercised in the control of the working expenses, the shareholders must not be surprised if in the future some increase were incurred As regarded the Company's ships, the greatest economy was exercised consistently with keeping them in the highest state of efficiency, which could not be done without spending a great deal of money. But by this means the Company were able, in the case of breaks or interruptions, to restore the communications in the shortest possible time, thereby saving loss of traffic and maintaining an efficient service for Governments, for the Press, and for the general public. After providing the usual amount for interest on debentures and debenture stock, and the usual two quarterly dividends, they were enabled to carry £10,000 to the maintenance ships' reserve fund and £50,000 to the general reserve fund, and the balance of £49,352 was carried forward to the next half-year. They had applied a further sum of £50,000 from the reserve fund in reduction of the cost of the Aden-Bombay No 3 cable, leaving a balance of £70,000 still to write off, but he was glad to say that the cost of this cable would have been wholly applied to reserve fund when they submitted the accounts to the end of their financial year up to the 31st of March next. The investments on account of their reserve funds amounted on September 30 to £423,000, but their market value showed an appreciation of nearly £60,000. Altogether, the accounts might fairly be considered very satisfactory. Generally speaking, their cables were in good working condition, but they were of all ages and lengths, and the numerous breaks and interruptions warned them that they ought to continue to add to their reserve fund, which, in the opinion of all those whose opinion was worth having, was still very inadequate—in fact, before they could consider it in a satisfactory state it ought to be double its present amount. He thought it right to take that opportunity of informing them of the actual facts with reference to their recent interruption on the East and West Coasts of Africa On the 24th ult. the Aden-Zanzibar cable became interrupted. They had two ships available for its repair—one belonging to the Eastern Company, which had just left Suez, and was on its way to Aden, the other belonging to the Eastern and South African Company, which was stationed at Cape Town. The latter company found that by hiring the Eastern Company's ship a saving of about a week in restoring the cable would be effected, and orders were immediately given for the Eastern Company's vessel to proceed to the spot. She hooked the Aden end at the second sweep, and communication was restored *vid* the East Coast on the evening of the 4th inst Meanwhile events had happened in the Transvaal of which they were all well aware, and their West Coast route had been called upon to carry not only the whole of the ordinary traffic, but also an enormous amount of additional traffic. Until the morning of the 30th ult the West Coast line was able to keep up to the work, but on the news that Dr. Jameson had crossed the Transvaal frontier, the line was occupied almost entirely by telegrams sent by and to European Governments. It might not be generally known that Governments had the right, under the International Telegraph Convention, of priority of transmission for all their messages, and this particular traffic was forwarded without exceptional delay. Immediately the East Coast route was restored the delay began to diminish, and on the 10th inst. they had completely recovered their normal working, which was owing not only to their having two lines available, but also to the cessation of the special Government traffic. It had been a time of great anxiety for the Company. They had desired above everything to be absolutely fair, and to treat the whole of their traffic in accordance with telegraph law, and he could not help saying that he thought they had succeeded. At any rate not a single complaint, as far as he was aware, had come from our own Government; on the contrary, he had reason to think that it was highly satisfied at the way its business was done Nor had they received any complaint from any other Government, foreign or otherwise, who had important interests in connection with South Africa.

Lord Sackville A. Cecil seconded the motion.

In the discussion which followed, **Mr. Baines, Captain Godsall,** and **Mr. Wood** advocated the payment of a higher dividend than 6½ per cent. in view of the satisfactory position which had been reached by the Company.

Mr. John Newton regarded the dividend as a very satisfactory one. The payment of very high dividends would simply attract competition.

The **Chairman,** in reply, stated that the directors would give their best consideration to the suggestions which had been made relative to the dividend, and if they could see their way to increase it at the end of their financial year without interfering with the policy they had hitherto pursued they would be happy to do so He, however, reminded them that if a cable or cables were laid across the Pacific the Company's traffic would be considerably affected.

The motion was unanimously adopted.

CAMBRIDGE ELECTRIC SUPPLY COMPANY, LIMITED.

Directors: D. Munsey, Esq., chairman; the Hon. C. A. Parsons, managing director; Sir B C. Browne, D.C.L.; Wm. C. Hall, Esq.; P. W. Latham Esq., M.D.; John B. Simpson, Esq. John H. Barker, general manager and secretary.

Report of the directors to be presented to the shareholders at the fourth annual general meeting to be held at the offices of the Company at Cambridge to-day at 12 noon:

Your directors have pleasure in reporting that the prospects of the Company continue to be satisfactory During the year 1895 there has been added to the Company's mains the equivalent of 3,016 8-c.p. lamps - making the total 14,660. A new bay has been added to the boiler-shed, with an additional boiler to meet the increased demand. Owing to the flood in November, 1894, the Company had to deepen their main intercepting wells to provide a constant supply of water; this was successfully carried out during the summer months. A new 75-unit dynamo and engine has just been added to the plant, bringing up the total capacity of the station to 522 units; this machine began work on January 11 of the present year A length of 903 yards of main conduit pipe has been added—making a total of 13,051 yards—whilst another sub-station fully equipped, has been constructed to supply Trinity College, Trinity-street, Bridge-street, and Sidney-street. At the end of the year one-third of the total supply was delivered from the sub-stations, resulting in a marked economy in fuel The number of units supplied during the year has been 150 510 against 112,084, an increase of 38,426, or 35 per cent. The Company has made a profit on the year's working of £1,489 8s. 10d., which added to £19 18s 2d. brought forward from last year, leaves £1.509. 7s and after paying £48. 11s. 11d. interest on debenture capital there remains a balance of £1,460 15s. 1d. Your directors therefore advise the payment of a dividend of 3½ per cent., absorbing £1,126. 17s. 11d., leaving £333 17s 2d. for depreciation and carrying forward During January, 1896, lamps equivalent to 860 8 c.p. have been connected in the new theatre Mr. Wm C Hall and Mr. J. B. Simpson retire by rotation; both are eligible and offer themselves for re-election. The auditor, Mr. Arthur Rutter, also offers himself for re election.

Report of the directors and abstract of accounts to be presented to the shareholders at the annual general meeting to be held at the offices of the Company, Carnaby-street, Golden-square, W., on Tuesday, February 4, at 12 30 p.m:

The directors in submitting their report for the year 1895, with accounts as certified by the Company's auditors, are pleased to state that the business shows a steady increase, and that the position of the Company has been considerably strengthened during the past year. The building extension in Carnaby-street has been completed and the station equipped with its full plant, and the working of this and of the supply generally has proved most satisfactory. The actions instituted by the Attorney-General on behalf of the parish and by the Windham Club, alleging nuisance from the plant at Mason's yard station, have been arranged. The directors have disposed of the greater portion of the engine plant at Mason's-yard station, and are replacing it by machinery of a similar description to that in use at the Carnaby-street station, and it is believed that the alterations have had the effect of putting an end to the annoyance complained of. The exceptional expenses incurred in the actions and by the consequent change of machinery have been charged to revenue. Certain negotiations have been in progress between the directors and holders of founders' shares with a view to the consolidation of interests, but no definite arrangement has been arrived at. In the month of November, in accordance with the intimation given in the report of last year, a further issue of £20,000 debenture stock was made to the shareholders at 2½ per cent. premium, making a total of £50 000 already issued. The net earnings of the Company during the past year have amounted to £14 580. 7s. 9d. Of this sum £5,498 was distributed in July last in payment of an interim dividend at the rate of 4 per cent. per annum for the half-year ending June 30, 1895, on the ordinary shares, and of 7 per cent. per annum on the preference shares. The balance, £9,082. 7s. 9d., together with the undivided profit of £95. 3s. 7d. from last year's account, leaves £9,177 11s. 4d. now to be dealt with. The directors propose to divide this amount as follows:

(*a*) By payment of a dividend at the rate of 7 per cent. per annum on the preference shares for the second half of the year	£3,500	0	0
(*b*) By payment of a dividend at the rate of 10½ per cent. per annum for the second half-year on the ordinary shares, making, with the interim dividend paid in July last, a total distribution of 7½ per cent. for the year	5,244	15	0
(*c*) By paying a dividend of £2 19s. 6d. per share on the founders' shares	297	10	0
(*d*) Amount to be carried forward to ordinary shareholders' undivided profit account	134	13	3
(*e*) Amount to be carried forward to founders' undivided profit account	0	13	1
	£9,177	11	4

Having been appointed Chief Secretary for Ireland, the Right Hon. Gerald W. Balfour, M.P., resigned his seat on the Board to the regret of his colleagues. Mr. Walter Leaf has been elected a director during the year, and in accordance with the articles of association he now retires, but, being eligible, offers himself for re-election. Mr. Bennett Fitch, M.I.C.E., is the director who retires by rotation under Clause 79 of the articles of association, and, being eligible, offers himself for re-election. The auditors, Messrs. Deloitte, Dever, Griffiths, and Co., also retire, and, being eligible, offer themselves for re-election.

YORKSHIRE HOUSE-TO-HOUSE ELECTRICITY COMPANY, LIMITED.

Directors: Grosvenor Talbot, Southfield, Burley, Leeds (chairman); George Henry Crowther, civil engineer, Huddersfield; Robert William Eddison (John Fowler and Co., Leeds, Limited), engineer, Leeds; R. Hudson, engineer, Gildersome Foundry, near Leeds; Samuel Ingham (Illingworth, Ingham, and Co.), timber merchant, Leeds; Arthur Greenhow Lupton (William Lupton and Co), cloth manufacturer, Leeds; John Thomas Pearson, The Hall, Melmerby, S.O., Yorkshire. Consulting electrical engineer: Robert Hammond, M.I.E E, Ormond House, Great Trinity-lane, London, E C. Secretary: W. T Green.

Report of the directors to be presented to the ordinary general meeting of the Company to be held at the offices of the Company, Whitehall road, Leeds, on February 4, 1896, at 2 30 p.m:

The directors submit herewith a statement of the income and expenditure for the past year, and the balance-sheet showing the assets and liabilities of the Company made up to December 31 last. The profit for the year (including £162. 1s 9d brought forward from the previous year) amounts to £6,483 3s 11d., which the directors propose shall be appropriated as follows: Reserve (for general purpose), £2,000; reserve (for depreciation), £1,300; payment of interim dividend at the rate of 4 per centum per annum upon the ordinary shares of the Company, numbered 101 to 10.100 inclusive, made for the half-year ending June 30, 1895, £1,000; payment of final dividend at the rate of 6 per centum per annum on the same shares for the half-year ending December 31, 1895, making 5 per cent. for the year, £1,500; payment of a dividend at the rate of 5 per centum per annum on shares numbered 10,101 to 18,948 inclusive on the amount called and paid up thereon from the respective times of payment, up to December 31, 1895, £165. 7s. 7d; balance to carry forward to next account, £517. 16s. 4d; total. £6,483. 3s. 11d. The works and plant of the Company have been maintained in an efficient state, and the quality of the supply of electrical energy continues

Digitized by Google

to give satisfaction. The number of lamps connected to the mains increased during the year from the equivalent of 19,858 to the equivalent of 32,539 35-watt lamps. A reduced scale of charges for current at a maximum price of 6d. per Board of Trade unit was brought into operation on July 1 last. The Leeds Corporation, in the last session of Parliament, introduced a Bill authorising them to construct and work electric or other tramways, which affected the Company's interests, and the directors obtained the insertion of a clause in the Bill by which the rights of the Company are protected. The Company's mains have been extended to Chapeltown, which has resulted in an encouraging demand for current. It having become apparent that the plant in operation will not suffice to meet the requirements of current that may be expected to arise not later than the winter of 1896, the directors have decided upon an important extension of the Company's works, and arrangements are being made to carry out that object. In order to obtain the necessary capital the remainder of the authorised capital, consisting of 9,900 ordinary shares was offered to the existing ordinary shareholders *pro rata* to their previous holdings, of which 8,848 shares were taken up. The retiring directors, Mr. Grosvenor Talbot and Mr. Robert Hudson, being eligible, offer themselves for re-election. Mr. John Gordon, jun., offers himself for re-election as auditor.

CONTRACTS FOR ELECTRICAL SUPPLIES

CONTRACTS OPEN.

Parma (Italy).—The municipal authorities of the city of Parma desire tenders by February 25 for the electric lighting of the city from June, 1897, to 1912.

Teneriffe (Canary Islands).—Tenders are invited for the electric lighting of the town of Santa Cruz, Teneriffe, for a period of 35 years. Particulars can be obtained at the Ministerio de la Gobernacion, Madrid, and tenders must be delivered by February 29.

Paris.—Tenders are asked for the supply of 500,000 kilogrammes of galvanised wire and various telegraphic supplies for the State telegraphs. Application for permission to tender must be made by February 3 to La Direction Générale des Postes et Télégraphes, Rue de Grenelle 3, where particulars may be obtained.

Brunn (Austria).—The Municipality desire offers for the construction and working of a central station for the supply of electric energy for lighting the town, for power, and, if required, for running a tramway. Tenders must be sent before March 31 to the Bürgermeister, Brünn, Austria, from whom particulars can be obtained.

Indian Railways.—The Great Indian Peninsular Railway Company are prepared to receive tenders for the supply of various stores, including telegraph materials and iron telegraph wire. Tenders must be delivered not later than 11 o'clock a.m. on February 6, at the Company's Offices, Copthall House, 48, Copthall-avenue, E.C.

Eston.—The Eston Urban District Council invite schemes for lighting the district by electricity. Such schemes to embrace (*a*) plan and estimated cost, (*b*) annual working cost and maintenance. Plan of the district may be seen and particulars obtained of Mr. T. W. Stainthorpe, A.M.I.C.E., district surveyor, Grangetown, Yorkshire, to whom the plans, etc., must be sent by May 1.

Huddersfield.—The Electric Lighting Committee of the Corporation invite tenders for the supply of two steam-boilers, four mechanical stokers and one surface condenser, with air and circulating pumps. Specifications and forms of tender may be obtained of Mr. A B Mountain, borough electrical engineer, St. Andrew's-road, Huddersfield. Tenders, endorsed "Tender for Electrical Machinery," must be delivered to the town clerk, Town Hall, Huddersfield, by February 4.

RESULTS OF TENDERS.

Chelsea (London).—The following were the tenders for proposed electric lighting buildings (boiler-house and engine-room), at Pitfield-street, for the Chelsea Vestry:

Nightingale, Albert-embankment	£10,494	0	0
Pattinson and Sons, Whitehall	8,854	0	0
Manlove, Alliott, and Co., Limited, Nottingham	10 540	16	0
Shelbourne and Co., Fenchurch-street	10 005	5	9
Atherton and Dolman, Poplar	8 535	0	0
Kirk and Randall, Woolwich	9,442	0	0
Jarvis and Sons, Hackney-road	9,926	0	0
Chessum and Sons, Haggerston	9,499	0	0
Wilkinson Bros, Finsbury Park	9,971	0	0
Coulsell Bros., Bethnal Green	9,383	0	0

BUSINESS NOTES.

Western and Brazilian Telegraph Company.—The traffic receipts for week ended January 24 were £2,804.

Stourport.—A resolution has been passed by a meeting of ratepayers giving power to oppose the Electric Tramway Bill if necessary.

Glasgow.—A committee of the Corporation has been appointed to visit Edinburgh for the purpose of inspecting the system of electric lighting there.

Portsea.—The Guardians have decided that the hospital and imbecile blocks shall be lighted by electricity at an estimated cost of £250 for the fittings.

Wrexham.—The Town Council have resolved that it is not desirable to grant any further extension of time to the Wrexham Electric Light Company.

Newcastle.—The poll of the ratepayers will be taken on February 20 as to whether the Corporation shall proceed in Parliament with the Tramways Bill or not.

Belfast.—The Belfast Corporation have appointed a deputation to visit Hamburg and other Continental cities and towns where the electric motor for tramways is in full swing.

Price-List.—We have received from Messrs. Beauland, Perkin, and Co., electrical engineers, of Leeds, a tabulated price-list of their "B. P. C" dynamos and motors, with illustrations.

City of London Electric Lighting Company, Limited.—The gross revenue for the quarter ended December 31 was £44,614, as compared with £29,637 for the corresponding period of 1894.

Dundee.—Some inconvenience was caused by a temporary failure of the electric light supply last week, owing to a breakdown in the boiler pumps and injectors at the central station.

Eastern and South African Telegraph Company, Limited.—The payment by warrants on February 1 of interest for the half-year ending January 31 on the 4 per cent. mortgage debentures is notified.

Linlithgow.—A committee of the inhabitants of Fauldhouse has been appointed to enquire into the probable cost of introducing electric light to supplant the present system of lighting the streets with oil lamps.

Richmond.—The new Free church which has just been built is to be fitted with the electric light throughout, and the work has been placed in the hands of Mr. C A. Hemingway, 10, Petersham-road.

Digitized by Google

New Swindon.—The Urban Council have instructed their clerk to obtain information from the authorities which have recently adopted the electric light

Eastern Telegraph Company, Limited.—The call upon the 5 per cent debentures due February 1 will be paid on and after that date at the banking-house of Messrs. Glyn, Mills, Currie and Co., 67, Lombard-street E C

Liverpool Overhead Railway.—The traffic receipts of this railway for the week ending January 26 amounted to £1,043 as compared with £943 in the corresponding week of the previous year being an increase of £100

Telegraph Extension in Africa.—A telegram from Matadi announces that the telegraph line of the Congo reached the Nkenge a few weeks ago, and that the work is being actively carried on in the direction of Lufu.

St. James's and Pall Mall Electric Light Company, Limited — The share transfer-books of this Company will be closed to February 10, preparatory to the payment of dividends for the half-year ended December 31, 1895.

Edinburgh — The Lord Provost's Committee of the Town Council have disapproved of the proposal by the National Telephone Company that the Corporation should lay underground tubes for telephone wires at the company's expense.

Llandrindod Wells.—The Urban District Council have resolved to accept a proposal for street-lighting by electricity for the next seven years at an annual charge per lamp of 58s. 6d. (including cost of renewals and repairs) for 70 lamps of 32 c p. each.

An Electric Railway for Brussels —A monorail electric railway, four miles long, is to be built to Tervueren in connection with the Brussels Exhibition of 1897. The curves will be 600 yards long, and each carriage will accommodate 110 passengers.

Cardiff —In the half-yearly estimates of the Lighting Committee the borough engineer has put down on the credit side a profit of £848 on electric lighting, a sum which will very nearly repay the principal and interest to be paid during the six months.

Cuba Submarine Telegraph Company.—The Board of the Cuba Submarine Telegraph Company, Limited, have resolved, after providing for the dividend on the preference shares, to recommend a distribution on the ordinary shares at the rate of 8 per cent. per annum

Portsmouth.—The Electric Lighting Committee have decided to recommend the Town Council to light Goldsmith's-avenue with electricity. The length of Goldsmith's avenue being 1,700 yards, the cost of laying the electric cable and putting up the lamps is estimated at £1 500

Venezuela Telephone and Electrical Appliances Company, Limited.—Coupon No. 11 of the 5 per cent. first mortgage debentures, due January 31, will be paid from that date at the Consolidated Bank, Threadneedle street, E C, or at Messrs. Westendorp and Co.'s Bank Amsterdam

Electricity in Mining.—The Pesterena United Gold Mining Company have laid down an electrical plant, and it is reported that, excepting a few minor items, the installation is practically completed to the 55-fathom level, and will be ready for starting towards the end of the first week in February.

Brechin.—The installation at the paper mill has been carried out by Messrs. Lowden Bros., Dundee. There are 110 of the newest type of incandescent lamps, and an engine from Messrs. Shanks Arbroath, of 8 h p, has been erected to drive the dynamo, which was supplied by Messrs. Mather and Platt, Manchester.

Coolgardie (West Australia).—Messrs. Addenbrooke and Scott, of London and Wolverhampton, have just shipped the first lot of plant, buildings, etc., for the public and private lighting and power of this town. They are doing it on what may be called the new system—viz., 220 volt lamps and simple three-wire distribution with accumulators.

City and South London Railway.—The returns for the week ended January 26 were £994, compared with £998 for the corresponding period of last year, being a decrease of £4 The total receipts for the half-year terminating as above were £4,035, compared with £3,999 in the same period of the preceding year, being an increase of £36.

England and America.—The *Financial Times* is responsible for the statement that since the unfortunate Cleveland message "an important American electrical concern, which was developing a large business in this country, has been practically paralysed for the time being." Our contemporary says that 20 of the engineers and assistants have gone back to their own country.

Daimler Motor Company, Limited.—This Company has been registered by J B. Purchase, 11, Queen Victoria-street, E.C, with a capital of £100,000 in £10 shares. The Company take powers to deal in patents, etc., relating to motors of all kinds, and among other matters to trade as electricians, mechanical engineers, rubber manufacturers, galvanisers, electroplaters, etc.

Company Amalgamation — Messrs. Swinburne and Co., Limited, announce that they have arranged to amalgamate their business with that of the Nalder and Harrison Construction Syndicate, Limited, the works being for the future combined under one roof at Bow Common-lane, E Mr. Holt, late general manager of Swinburne and Co, will join the Board of the amalgamated companies.

Electric Traction on the Underground Railway.—Sir Edward Watkin has announced that the directors of the Metropolitan Company had always wished to substitute electricity for the steam traction now in use but hitherto there had been no scheme whereby heavy trains could be moved by electric power, except at greatly increased cost. Arrangements, however, had now been made which might soon overcome all difficulties

Pembroke Dock.—At a special meeting of the Town Council, Mr. Ford (Carew) and Mr. Baker, electrician, of Llanelly, were introduced to the meeting, and had an interview relative to the suggested lighting of the town by electricity, after which it was decided that Mr H A. Jones Lloyd, chairman of the Gas Committee, should confer with Mr. Baker upon the details of the matter. The result of their conference will be made known to the Council at their next meeting

International Exhibition of Motor Carriages —An arrangement has been completed between Sir Somers Vine, on behalf of the Imperial Institute, and Mr. Harry J. Lawson, director of the Daimler Motor Company, for the great international exhibition of motor carriages which the Prince of Wales has consented to open at the Imperial Institute in May. This exhibition will remain open until August. Its main object is to give an impetus and public interest to the industry of motor carriage manufacture.

Bradford.—The Gas and Electricity Supply Committee of the Town Council have appointed Mr. Thomas Parker to draw up plans for the proposed extension of the electricity works of the Corporation. The members of the Tramways, Baths, and Team Labour Committee have visited Leeds for the purpose of inspecting a new system of electric tramway traction invented by Mr. Christopher Anderson, of Leeds, of which the characteristic feature is the substitution of a closed conduit for the ordinary slot conduit.

Pembroke —A public meeting of ratepayers is to be convened to protest against the Corporation entering into any agreement with a syndicate which is in course of formation for the purpose of lighting the streets of Pembroke by electricity. The syndicate is understood to consist of local men, some of whom are members of the Corporation, and they expect to realise a profit of at least 25 per cent. The opponents of the proposal will advocate the desirability of the Corporation taking the lighting of the streets into their own hands.

Tunbridge Wells.—Mr. H. L. P. Root, the borough electrical engineer, reports that for the first quarter's working 25,323 units were sold to consumers at 6d. per unit, and the cost of generation was 2·9d per unit. The total number of lamps connected and applied for are about 6 000, and new applications are steadily coming in; the past quarter thus shows a net profit of several hundred pounds over working expenses. The probable annual revenue may be put at between £1,500 and £2,000. Interest on capital and sinking fund will represent a charge of 6 per cent.

Kingston-on-Thames —At a meeting of the Town Council the Lighting and Market Committee reported that Mr. Russell, representing Messrs. Siemens Bros., had informed them that the arc lighting mains had been tested, and the company were prepared to relay such lengths where the insulation was found, when tested, to be below a certain point. Messrs. Siemens Bros. had offered to lay at their own expense a new and improved arc light cable upon the Corporation opening and filling the necessary trench. The offer was accepted, subject to the same being guaranteed for three years

Anglo-American Telegraph Company —The directors of the Anglo American Telegraph Company, Limited, after placing £12,000 to the credit of the renewal fund, recommend a balance dividend of 18s. per cent. upon the ordinary consolidated stock, and of £1 16s. per cent. upon the preferred stock, for the year ended December 31, 1895 both payable on February 8 next, less income tax, leaving about £794 to be carried forward. The above dividends, together with those already paid, will amount to £2 9s. per cent. on the ordinary consolidated stock and £4 18s. per cent. on the preferred stock for the year 1895.

Swansea.—Colonel Walter Mender Ducat, R.E., inspector under the Local Government Board, has held an enquiry into the proposal of the Corporation to borrow £60,000 for the purposes of electric lighting and the erection of a dust destructor. Mr. S. T. Evans, M P, who represented the Corporation of Swansea, stated that the system would be the high-tension transformer scheme, which had proved a success elsewhere, and the Corporation would be able to cheaply destroy their refuse and at the same time supply heat for the purposes of the electricity part of the scheme. It is stated that the poll of the burgesses and property owners on the triple electric scheme will take place about February 21, and it is likely that before this Mr. Preece's report will be made known.

Southampton.—At a meeting of the Harbour Board a letter was read from Mr. J. T. Hamilton, secretary to the Southampton Electric Light and Power Company, Limited, stating that at a meeting of his directors the intention of the Harbour Board to lay down plant for the generation of the electric current required in connection with the crane work and lighting of the quay and pier was considered, and, as they were anxious not to lose the Harbour Board as a customer, after having specially laid down plant to meet the Harbour Board requirements, they were willing from the 1st inst. to reduce the charge for power to 4½d. per unit, and at the close of the present agreement with the company to reduce the price both for power and lighting to a uniform charge of 4½d. Alderman Bone gave notice that he would move the rescinding of the Board's previous resolution on the subject, as they decided some months ago to lay down plant to supply their own electricity.

Calne.—The Urban District Council are considering the question of providing the town hall and parts of the town with electric light. Mr. H. E Hall, of Tonbridge, has reported that from the observations of Mr Maundrell on the flow of the stream it might be safely assumed that, with an efficient turbine, about 15 effective horse-power might be obtained from the present water supply.

Digitized by Google

For the efficient lighting of the town hall, offices, etc., about 60 or 65 incandescent lamps of 16 c.p. each would be required, and the power to maintain these, if all lighted at once and at one time, would be 6·5 h.p The power at disposal would also maintain eight arc lamps each from 1,500 c.p. to 2,000 c p. The cost of electric plant, including dynamo of best make and of sufficient size, with a proper switchboard and appliances, the wire for the town hall standards and plant for the arc lamps, would be about £475. The total cost of the turbine would be about £200. The matter has been referred to the committee.

Telephones in Yorkshire.—In his reply to the petition from the West Riding for further telephonic facilities, the Postmaster-General intimates that he is prepared, after enquiry as to cost, to recommend to the Treasury the provision of additional trunk wires in the Riding, and further states that the list which had been forwarded to him went beyond that area, and included wires to Liverpool, Manchester, Morecambe, Newcastle, Nottingham, Birmingham, etc. Some of the larger requirements would be met by the backbone system of trunk wires the construction of which had for some time been in hand, and it was thought it would be desirable to await the completion of that system, and to see how, in conjunction with the wires to be transferred from the company, it met the requirements of the public. The Postmaster-General holds out no hope of the time for conversation on trunk wires being extended from three minutes to five. He states that the limit has been adopted by the International Telegraphs Union, and experience has shown that it is ample.

Edinburgh.—The Electric Lighting Committee have under consideration the contemplated extension of the system in the city, and authority was given for the acceptance of offers for boilers, superheaters mechanical stokers, steam dynamos, and other appliances, at a total estimated cost of over £20,000 Instructions were given that in the meantime the extension from the Literary Institute southward to Salisbury-place, and that along Fountainbridge westward from Freer-street to Viewforth, together with the erection of lamps on the Dean Bridge, be proceeded with. It was resolved to recommend the Magistrates and Council to oppose the petition to the Privy Council by Dr. Hopkinson and the Westinghouse Company, praying that the "patent three-wire system," which expires in July next, should be extended for a further term of years. It is understood that the Edinburgh Corporation have never admitted any infringement of the patent on their part. It was decided to advertise for a resident electrical engineer in succession to Mr. Monkhouse, offering a salary of £400 per annum.

Sheffield —A special meeting of the Council has been held to consider the tramways question. The Sheffield District and Rotherham Tramways Company had applied to the Council for their assent to a Bill in Parliament, and the matter has occasioned much discussion and several meetings. The Parliamentary Committee reported that in view of the growing feeling in favour of tramways being acquired and worked by municipal corporations they could not recommend the City Council to give their consent to the Bill. They also recommended that a deputation be appointed, and that the Association of Municipal Corporations and other municipalities be invited to send representatives to wait upon the Presidents of the Local Government Board and the Board of Trade, with a view to endeavour to obtain their support for the suspension of the Standing Orders of Parliament which prevent municipal corporations and other local authorities from working tramways, and that the Right Hon. A. J. Mundella and the Right Hon. C. B S. Wortley be invited to attend with the deputation. These recommendations have now been adopted.

Cardiff.—The Corporation Lighting Committee have again met to consider the statements of the four fitters—Johns, Melhuish F. A. Parker, and Knight—as to certain defects in the engines and boilers at the electrical lighting station in which they are employed, defects which they allege are sufficiently serious to afford ground for anxiety. Alderman P. W. Carey presided, and the investigation lasted for a couple of hours. Mr. Appleby, manager of the works, was present during the first part of the meeting. The Chairman said they would remember that at the last meeting the four men were invited to send in a written report. They had done so, and the report was before him. (The document was bulky and voluminous.) Mr. Morgan Morgan proposed that an expert mechanical engineer report to the committee upon the state of the engines and boilers, and also on the allegations contained in the letters of the four fitters, so far as they referred to such engines and boilers. Mr. W. Evans seconded, and it was carried. and Mr. J. H. Hallett (Cardiff Docks), consulting assessor for the Board of Trade, was unanimously appointed as the expert.

Newcastle-on-Tyne.—A meeting of ratepayers has been held to consider the tramway question. Councillor Gillespie pointed out that they had yet to learn that the electric system at Bristol worked out well financially. Whatever the result of the poll, he trusted the lease would be given to those men who could show by the deposit they offered, by the cheapness of the fares, by the quickness of the service, and by the good maintenance of the lines, etc., up to the end of their control, that the city in the end would have a valuable property. This in his humble judgment, was to be obtained by the cable system. Alderman Baxter Ellis made a strong speech in favour of the application of electric power. He thought they should pause when Leeds and Birmingham were favouring a large expenditure of capital in improving and extending their electric systems. Mr. Cairns defended the electric system from a financial point of view, and Mr. Wm. Crossling moved a motion to the effect that the meeting was of opinion that at present it was inexpedient to proceed with the Tramway Bill for the adoption of the cable or any other system, until the whole question had been referred back for further consideration. Mr. Armstrong seconded the motion, which was carried unanimously.

Provisional Orders —The Highways Committee of the London County Council reported that three applications have been made to the Board of Trade for electric lighting provisional orders this session. Two of these were by the Vestries of Battersea and Newington as regards their respective districts, and appeared to require only very slight amendments. The third order, applied for by the County of London and Brush Provincial Electric Lighting Company, and entitled the County of London (South) Order, relates to the St Saviour's district and the parishes of Newington, Battersea, Lambeth, and Camberwell. The district of St. Saviour is already included in the areas referred to in two other companies' orders, the parish of Newington in one, parts of the parish of Lambeth in two (whilst the Vestry also itself has an order), and the parish of Camberwell in two The Vestry of Battersea strongly objects to the granting of the order so far as relates to that parish, and it appeared to the committee that ample provision is made under previous orders for the electric lighting of the district referred to in the order now asked for. They accordingly recommended that the Board of Trade be asked not to accede to the application for the County of London (South) Electric Lighting Order. The report was adopted.

Aberdeen —A committee has been appointed by the Harbour Board to report as to whether the necessary current for lighting the quays should be obtained from the Corporation mains, or by generating plant to be procured by the Board. The Corporation electric lighting accounts show a profit on the past year's working of £435 0s. 9d. The income was £3,611. 8s 9d., and the cost of maintenance £1,356. 18s. Out of the balance interest on mortgages has to be paid, and large sums have been written off for depreciation on buildings, machinery, etc , and a sum put to the credit of the sinking fund—these items together making a total of £1 819. 10s., and leaving a clear balance of £435. At the June balance there was a deficiency of £109 so that the year's results are regarded as highly satisfactory. It is expected that the Town Council will on an early date reduce the price of the light by about 1d. per unit. The quantity of electricity generated in Board of Trade units was 159,777, and the quantity sold was—for public lamps, 8,257 units; to private consumers by meter, 130,115 units; total, 138 372. The quantity used in the works was 1,769 units, and the total accounted for is thus 140,141 units, leaving a leakage of 19,636 There are 10 public lamps The Gas and Electric Lighting Committee of Aberdeen Town Council have had under consideration the accounts for the year in the electrical department It was resolved that the £435 of clear profit should be utilised in establishing a reserve fund which, the Board of Trade has decided, may amount to one-fifth of the whole capital. From this fund any subsequent deficit or extraordinary expenditure may be met It was decided to recommend to the Council to make a reduction of 1d. per unit, making it 5d. instead of 6d. as at present and to reduce the meter rents by one-half.

Birmingham.—The Public Works Committee has reported in favour of a trial of overhead electric traction on the Nechells line of tramways. The length of line is about 2¼ miles, and at present the tramcars are drawn by horses, some of the streets traversed being too narrow to permit of the use of steam traction The electric current will be carried along under the footpath, and will, at intervals of 50 to 60 yards, be conducted through posts to the overhead wire, these posts, which are to carry two branching lights, being also used as lamp-posts The cars will be "actuated" by an ingeniously contrived arm, working from the top of the car, and connecting itself with the overhead wire The wire will be carried along only one side of the street, with occasional crossings at the turnout places. The committee have considered the question of danger very carefully. Their conclusion, based upon the three years' experience of Walsall, and upon the experience of Bristol and other places, is that there is really no danger, the electric current, even if the wires should break, being too weak to inflict injury. As a matter of fact the breakages of wires are infrequent, only three having occurred in Walsall during the three years, and no damage to any person resulted from these The conditions imposed by the committee are: first, there is to be no cost to the Corporation: second, the execution of the work is to be under the supervision of the Public Works Committee and of the Board of Trade; third, the extra lighting of the public lamps is to be borne by the company; fourth, an additional service of trams is to be provided by the company; and, fifth, the company undertakes, after six months' trial, followed by three months' notice from the Corporation, to remove the wires and everything connected with them.

London Lighting Extensions.—Notice under the Electric Lighting Acts and Orders has been given to the London County Council by the County of London and Brush Provincial Electric Lighting Company, under the Wandsworth Electric Lighting Order, 1892, of intention to construct 38 large transformer-boxes in the Wandsworth district; but as the Council were informed that the proposed positions of the boxes had not been approved by the Wandsworth District Board they withheld their approval so as to give the District Board a free hand in the matter. Notices have also been given by the Vestry of St. Pancras to lay mains in Great College-street; from the House-to House Electric Supply Company to lay high and low tension mains in Evelyn gardens and Cranley-gardens, to construct three transformer-boxes and three surface boxes, low-tension mains in Sussex-place, and high and low tension mains in Fulham road; by the London Electric Supply Corporation to lay distributing mains in Battlebridge-lane, Tooley-street; and from the Westminster Electric Supply Corporation

Digitized by Google

to lay mains in South Eaton-place. The committee recommended that these works be sanctioned ; and they also recommended that sanction should be given to the application from Messrs. Ellington and Woodall to the laying of the London Hydraulic Power Company's mains in Mount street, Dover-street, St George (Hanover-square), Park-crescent, and in part of Marylebone road and part of Albany-street. The Vestry of Islington will begin to supply electricity for lighting purposes in the main thoroughfares of the parish to-day. The streets however, will not be illuminated with electricity until March. The Hackney Vestry have adopted a scheme of electric lighting in combination with a dust destructor The capital outlay will be £80,000, but it is estimated that the parish will reap a profit. During the discussion before the Vestry it was stated that Shoreditch, Tottenham, and Walthamstow were about to adopt similar schemes.

PROVISIONAL PATENTS, 1896

JANUARY 20

1396. Improvements in machinery or apparatus for transmitting motion from electric motors to other machinery. William Wilson Hulse, 46, Lincoln's-inn-fields, London.

1401. Improvements in electrical gas-reaction apparatus. Aloys Adrién Naville, Philippe Auguste Guye, and Charles Eugene Guye, 11, Southampton-buildings, Chancery-lane, London.

JANUARY 21.

1427. Improvements in and connected with telephonic apparatus. Hugo Marcuse, 70, Market street, Manchester. (Complete specification.)

1443. Improved means of intercommunication by telephone, part of which is applicable to other electrical apparatus. John James Mann 4, St. Ann's-square, Manchester.

1457. Improvements in or connected with incandescence electric lamps. Charles Frederick Stearn, 47, Lincoln's-inn-fields, London. (Charles Frederick Topham, Switzerland.)

1480. Improvements in electric gas-lighting apparatus. Edward Griffith Brewer, 33, Chancery-lane, London. (Henry Clay Farquharson and Denise Frank Root, United States.)

1487. An improved microphonic transmitter. Philippe Charollois, 45 Southampton-buildings, Chancery-lane, London.

1498. Improvements in or relating to electric batteries. Walter Grimes, 323, High Holborn, London.

1511. Improvements in the manufacture of filaments for electric incandescent lamps. Frank Eustace Wilkins Bowen, 6, Bream's-buildings, Chancery-lane, London.

1518. Improvements in means for the distribution of electricity simultaneously to circuits requiring current of uniform pressure and to circuits having variable load. Henry Edmunds, 47, Lincoln's-inn-fields, London. (Gulielmo Mengarini, Italy.)

JANUARY 22.

1559. Improvements in making gases and steam by electricity. John Henrique Dunn and John Parsons, 272, Holloway-road, London.

1563. Improvements in gravity electrical contact-makers. Richard Pearson, 53, Chancery-lane, London.

1564. An improved process for utilising peroxide of lead in the manufacture of elements for voltaic batteries. Desmond Gerald FitzGerald and Charles Nigel Stewart, 53, Chancery-lane, London.

1565. Improvements in electric switches. Thomas Harper, 55, Chancery-lane, London.

1574. An improvement in electricity meters. Siemens Bros and Co., Limited, and John Nebel, 28, Southampton-buildings, Chancery-lane, London.

1575. A process for the electrolytic production of zinc from its ores. Siemens Bros. and Co., Limited, 28, Southampton buildings, Chancery-lane, London. (Siemens and Halske, Germany.) (Complete specification.)

JANUARY 23.

1611. Improvements in and relating to holders for incandescent electric lamps. William McGeoch, jun., 96, Buchanan-street, Glasgow. (Complete specification)

1669. Improvements in or relating to electric batteries. William Turner, 323, High Holborn, London.

1678. Improvements in electrodes for electrolytical purposes. William Digby, 45, Southampton-buildings, Chancery-lane, London. (Albert Edward Woolf, United States)

JANUARY 24.

1685. Method of utilising primary induced currents of dynamo-electric machinery. Thomas Cooper, 69, Mill-street, Rycroft, Walsall.

1687. Isolator for fastening electric conducting wires. Heinrich Rudolf, 18, Petherton-road, Canonbury, London. (Complete specification.)

1695. Improvements in connection with electric tramways. Thomas Meacock, 18, Burlington-chambers, New-street, Birmingham.

1715. Improvements in and relating to ships' telegraphs. John William Ray and Robert Coleman Saxby, 26, Castle-street, Liverpool.

1775. Improvements in dynamo machines. Alphonse Isidore Gravier, 77, Chancery-lane, London.

JANUARY 25.

1782. Improvements in apparatus for testing magnetic quality. James Alfred Ewing, Langdale Lodge, Cambridge.

1793. The Inglis electrical photographic lamp for studio purposes. James Martin Inglis, 19, Queensbury-street, Edinburgh.

1796. Improvements in means for or connected with the charging of portable electric secondary batteries or accumulators. Walter Gardwood Mulliner and Wilson Henry Sturge, 12, Cherry-street, Birmingham.

1838. Improvements in electrically-driven wool-shearing or hair-clipping machines. Harry William Charles Cox and Gershon Bowmar, 1, Queen Victoria-street, London.

1842. Improvements in holders for electric glow lamps and analogous electrical contact devices. Thomas Richard Davis Kenny, 46 Lincoln's-inn-fields, London.

1843. Improvements in the means and apparatus for connecting electrically-propelled vehicles on tram and railways to fixed conductors. David Urquhart and Frank Wynne, 17, Victoria-street, Westminster.

SPECIFICATIONS PUBLISHED

1888.

11963. Electric rail, etc., systems. Smith. (Second edition.)

1892.

9983. Electrically propelling railway vehicles. Thompson. (Ries and Henderson.) (Second edition.)

1894

10169. Voltaic batteries. Blot. (Second edition.)

NOTES.

Safety Rules.—It is stated that the Japanese Electrical Association has asked the Government to issue regulations regarding electric light and power, and offered its services in preparing such a set of rules.

Tramcar Speeds.—The United States Supreme Court has upheld the Brooklyn by-law limiting the electric tramway to a speed of eight miles an hour, and six miles an hour in the more densely-populated parts of the city.

Tramways and Trees.—The running of the Coventry tramways was stopped suddenly last week owing to a branch of a tree being allowed to fall on to the overhead wires. The damage was repaired and the cars running again in less than half an hour.

Liverpool Engineering Society.—At the annual dinner of the society Mr. Maginnis, president, in the chair, there was a large attendance, amongst those present being Lord Derby (Lord Mayor of Liverpool), Mr. W. J. Pirrie, J.P. (Lord Mayor of Belfast), and Mr. T. H. Ismay.

Incandescent Gas Patents.—The German Patent Office has confirmed the patent of Herr Rudolf Langhaus. The invention consists of depositing the incandescing material upon a gauze of exceedingly fine platinum wire by means of electrolysis, so as to produce a mantle that will bear rough usage.

Power Transmission.—According to the *Elektrotechnischer Anzeiger*, the city of Guatemala, in Central America, is to be supplied with electricity for lighting and power from a waterfall 36 kilometres (22 miles) distant. The three-phase system is to be adopted, with a potential of 10,000 volts over the line, and transformers at each end.

Board of Trade Regulations.—We have received from the Board of Trade a copy of the model regulations which this Department, after consideration of the representations made by undertakers under electric lighting orders, and by associations, etc., interested in the matter, propose to adopt. The new regulations will be given in full for the purpose of reference in our next week's issue.

A High-Tension Shock.—Signor Nizzola, writing in *L'Elettricista*, says that a workman at Frankfort-on-the Main touched a wire and received a shock at a potential of 2,900 volts. Though apparently killed, he was revived by artificial respiration in half an hour. As it is stated that the man was standing in good contact with the ground, it is to be presumed that the contact with the wire was not a very good one.

Electrosciography.—This is to be the name for the process of taking photographs on Prof. Röntgen's methods. It is, perhaps, not pretty, neither are the photographs, but it has this advantage over using the same number of syllables of plain English. If one writes of the process under the title of "electric shadow printing," it offers an opportunity for anybody to say it is nothing of the sort, whereas few people will concern themselves as to the exact meaning of a word like electrosciography.

Obituary.—We regret to announce the death, at the age of 42, of Mr. Augustus Calder, which took place on the 3rd inst. at his residence, Wandsworth Common. Mr. Calder, about 15 years since, entered the service of the National Telephone Company, and rapidly rose to the position of metropolitan manager. It was under his superintendence that the complicated undertaking of metallic circuiting the telephone system of London was carried out. The death of M. Jules Reiset, the French chemist, is also announced.

New Spanish Thermostat.—The *Revista Tecnológico Industrial*, the monthly publication of the Barcelona Association of Civil Engineers, contains a note on an apparatus invented by Don Juan Vila y Forns, of Gerona, which is designed to be used as a fire-alarm, or in any case where it is desirable to indicate the attainment of given temperatures. The apparatus consists of a series of thermometers, with metallic contact points at various temperatures completing circuits containing a battery and electric bell.

The Metric System.—As evidence that the retailers of the country are not opposed to the adoption of the metric system, the secretary of the New Decimal Association calls attention to the fact that the Metropolitan Grocers' and Provision Dealers' Association have quite recently passed resolutions in its favour. The Bolton Grocers' Association also has passed a resolution approving the recommendations of the Select Committee on Weights and Measures, and urging the present Government to give effect thereto; and the Glasgow United Trades Council has resolved to the same effect.

Chemical Society.—The *Proceedings* of the society contain a note by Dr. T. Ewan on the electrolytic conductivity of formanilide and thioformanilide. The majority of the amides are too little soluble in water to allow of measurements of electrolytic conductivity being made. Others, again are decomposed by water too rapidly into acid and amine. The conductivity of formanilide shows that it possesses feebly acidic properties. In aqueous solution the sodium compound of formanilide is completely decomposed. In the case of thioformanilide, the sodium compound appears to exist in aqueous solution.

Sunshine Recorder.—An electric sunshine recorder, devised by Messrs. Hunt and Duenckel, of St. Louis, Missouri, consists of a pair of balanced bulbs filled with liquid, connected by a tube and suspended on a knife-edge. One of the bulbs has a bright surface, and is screened from the rays of the sun by a cover, while the other is blackened. The heating of the blackened bulb causes the expansion of the air in it, and drives the liquid over into the screened bulb. This disturbs the equilibrium of the pair, which tips over and causes an arm carrying contact points to dip into mercury-cups and to actuate an electric register. The cooling of the bulb allows the liquid to flow back and opens the electric circuit by bringing the arm out of contact with the mercury-cups.

Electric Fan. — In America, for climatic reasons, more attention is given to fans than in this country, and in the January number of the New York *Electrical Engineer* there is described an electrically-driven fan. Instead of putting the motor on the shaft the fan blades are arranged inside of a ring armature, with the field magnet located outside of the armature. The commutator is placed on the hub of the fan, and the fan blades are utilised as conductors between the commutator sections and the armature. In thus utilising the fan blades as conductors they are insulated from each other, and the armature ring is wound in sections corresponding in number to the number of the fan blades, the latter being, of course, electrically connected with the commutator and armature sections.

The Coming Locomotive.—Speaking at a meeting of mechanical students at Crewe last week, at which Lord Stalbridge, the chairman of the London and North-Western Railway Company, was also present, Mr. Webb, chief locomotive engineer, referred to the recent run from Euston to Carlisle, 300 miles, without stopping, and declared that he was ready, if necessary, to run trains from Euston to Aberdeen without stopping, and guarantee punctuality of arrival. He was prepared also to run electric railways,

Digitized by Google

and he predicted that a few years hence electric trains would be run to all the great centres at a speed they could hardly now realise. From which it would appear that some form of electric traction for railway work has been considered by the officials of at least one great company.

Royal Dublin Society.—Last week at a meeting of the society, presided over by Sir Howard Grubb, Mr. Charles E. Fitzgerald, M.D., read a paper "On Carborundum, a Substitute for Emery." He said that the paper was in reality by his son, who was at present engaged at the factory at Niagara, where carborundum, the invention of Mr. Acheson, is manufactured. Carborundum was discovered in 1891. Its great hardness rendered it a very valuable substitute for emery. A discussion followed, in which Dr. Bindon Stoney, Dr. Moss, Dr. W. B. Pearsall, the chairman, and others took part. Mr. John R. Wigham read a paper on "A Method of Using Common Petroleum as the Illuminant for Beacons and Buoys." The principle was that of a horizontal wick, and the light would burn for a month.

Underground Telephone Cables.—A remarkable report appears in the New York *Electrical Engineer* as to the electrolysis of telephone cables in Pittsburgh: "Every underground cable in Alleghany City," the despatch says, "all underground wires in Bellefield, and part of the system of East Liberty and of the West End have been abandoned, the down town district practically being the only part of the system in the two cities that has escaped the ravages of electrolysis. The wires affected are the property of the Central District and Printing Telegraph Company, otherwise known as the local telephone company. The wires had recently been placed underground at a cost exceeding 50,000dol. The water companies, telegraph companies, electric light companies, natural and artificial gas companies have also suffered to a large extent."

The Riker Electric Cycle.—The New York *Electrical Engineer* gives an engraving and a short account of a motor cycle designed by Mr. A. L. Riker, and is intended to be run at a maximum speed of 12 miles an hour over ordinary roads, maintaining that rate for four hours, and thus giving a travelling distance of 48 miles. The machine is a four-wheeler, and appears closely to resemble two safety bicycles coupled together, so as to run side by side, but the rider sits high up and forward, his feet resting on a bar above the front wheels, while the motors and battery are contained in a case between the two rear wheels. Two motors are employed, each of ½ h.p. and weighing 24lb. These are geared independently to the two rear wheels. The storage batteries are of a light lead-zinc type and weigh 135lb. The total weight of the vehicle, including everything, is 310lb.

Plant Life.—In reference to the action of electricity on vegetation, M. Bonnier, in the *Revue Générale de Botanique*, states that a continuous electric light promotes the formation of chlorophyll, and brings about, at the same time, a simpler anatomical structure of the leaves. The distribution of the chlorophyll in the tissues is more extended than in ordinary daylight; chlorophyll grains make their appearance in the cortex as far as the endoderm, and even in the medullary rays and the pith. The palisade tissue of the leaf is reduced, or entirely disappears, and the epidermal cell walls are thinner, while the bark is less developed, and the various tissues of the stem are less differentiated. A discontinuous electric light is intermediate in effect between sunlight and a continuous electric light. Alpine plants cultivated under a continuous electric light exhibit points of structure identical with those of Arctic plants, which are exposed to almost continuous sunlight in the summer. In the *Bolletino* of the Italian Botanical Society, Prof. A. Aloi brings forward evidence that both terrestrial and atmospheric electricity exercise an influence on the germination of seeds and the growth of plants.

Society of Engineers.—The first ordinary meeting of the Society of Engineers for the present year was held on Monday at the Royal United Service Institution, Whitehall. On the motion of the president (Mr. S. Herbert Cox), a resolution was passed expressing sympathy with the Queen and Royal Family in the loss of Prince Henry of Battenberg. The retiring president (Mr. W. G. Peirce) presented the premiums awarded for papers read during the past year. Mr. S. Herbert Cox, the new president, afterwards delivered his inaugural address, which was devoted to a review of the gold-mining industry from an engineering point of view. In dwelling on the difficulties of a dry treatment of gold-bearing ores, the president urged the necessity which existed for a new process which would be applicable in those districts in which sufficient water could not be obtained to allow of the ordinary treatment. The chlorination and cyanide processes were described, and the hope expressed that before the present year closed even more successful results would be obtained.

Japan Tramways.—An electric tramway established at Kioto, in Japan, is described and illustrated in *L'Energie Electrique*. The tramway has been laid by the Thomson-Houston Company, and the current is taken from a central station, which supplies power to a number silk-mills as well as the electric lighting of Kioto. The source of power is a canal from Lake Biwa, which is also used for navigation and irrigation purposes. There are 20 Pelton wheels of about 120 h.p. working 12 dynamos, arrangements being made for the employment of alternating currents of from 1,000 to 2,000 volts, and a three-phase system at 2,000 volts, as well as a 500-volt continuous current, the total output being at present about 1,200 kilowatts. One curious feature is an inclined plane 700 metres long, with a fall of 7 per cent., which is used for transporting barges from the canal to the River Ujigawa, and *vice versâ*. This is worked by a cable driven by a 50-h.p. Thomson-Houston motor. The electric tramway is 18 kilometres (11¼ miles) long, and is worked with 26 cars fitted with Thomson motors. It is stated that the results of this tramway have been so encouraging that the Municipalities of Tokio, Yokohama, and Osaka have decided on adopting similar lines.

Institution of Mechanical Engineers.—At the annual general meeting of this institution the president, Prof. A. B. W. Kennedy, occupied the chair, and there was a large attendance. The annual report of the council stated that at the end of last year the number of names in all classes on the roll of the institution was 2,270, as compared with 2,222 at the end of the previous year. The council had bought a site at Storey's-gate, Westminster, with the view of providing a permanent home for the institution. Amongst other technical matters which had been dealt with by the council during the year, the report mentioned a memorial to the President of the Local Government Board for the repeal of existing statutes so far as they prevented mechanical locomotion on common roads, apart from traction engines. Should the appeal prove successful, the council were sanguine enough to anticipate with confidence the speedy development of a branch of mechanical engineering, which might even call forth an amount of enterprise exceeding anything that had yet arisen in connection with the remarkably rapid growth of the cycle manufacture. Prof. Kennedy was thanked for his services as president, and the chair was taken by Mr. E. Windsor Richards, the president-elect.

The Chapsal Brake.—The *Compte Rendu* of the Société des Ingenieurs Civils de France gives in full the description of the Chapsal electro-pneumatic quick-acting brake recently referred to in these columns, which was communicated to the Société by M. Georges Lesourd. The details are somewhat complicated, and would be scarcely comprehensible without a reproduction of the diagrams, but the principle is controlling the working of the triple valves of the Westinghouse brake by means of electro-magnets worked by an accumulator carried on the engine. Two circuits are used, one for braking and one for taking off, and with modifications the system can be applied to most other continuous brakes besides the Westinghouse. The pneumatic action is not interfered with, so that in case of the electric apparatus failing from any cause the ordinary continuous brake remains available. The amount of braking given is much more adjustable, and in case of the brakes coming on from a burst tube or broken coupling the train still remains under the control of the driver, and can be stopped where convenient. The action of the brake, being electrical, is, of course, simultaneous on all the carriages, however long the train may be.

Technical Training.—Writing in the *Harvard Graduates' Magazine*, Prof. Ira N. Hollis considers the framing of a course of mathematics and physics. Though the views expressed are referred to mechanical engineering, they have an equal bearing on the electrical branch. Engineering, in the abstract, is a branch of both mathematics and physics, but the principal question that meets one in carrying out any problem in construction is the economic question. One of the main elements of success is a thorough knowledge of materials and their combinations into the most economical forms. The formulæ to be applied may be worked out by the mathematician, but there is always a factor or coefficient determined by experience. This experience must begin in the schools, in order that men may appreciate as early as possible the value of gaining knowledge after graduation in such a form that it can be used. The great danger to the engineer, therefore, in the exclusive study of mathematics lies in the tendency to work out everything from the ideal standpoint, and to neglect the more important practical coefficient. Again, though the study of physical science is of the greatest value, yet there is constant temptation to follow methods too refined for the workshop. The engineering student has usually little time to spend over small experiments. But the schools will develop a man whose talent and capacity for work will enable him to study and to retain the higher branches of mathematics and physics, and at the same time to grasp their practical application to the need of modern ife.

An American Notion.—The following is intended as a serious communication to a serious paper, the *Canadian Engineer*. It is entitled "Overcrowding in the Installation of Generators," and is the production of Mr. Wm. Golding, a civil engineer, of New Orleans. Mr. Golding says: "It is the practice to instal as many electric generators in a given area as the floor space will admit, never thinking that the electric fluid which is being gathered from the atmosphere may become exhausted. The object of this note is to direct attention to the probable fact, that as all of the known ingredients of the atmosphere may be separated, the quantity of electricity collectible upon a given area may be limited. As is well known, the life-sustaining property of the atmosphere, whether for animal or plant life, becomes exhausted by overcrowding, thus suggesting that the supply of electric fluid over a given area may also become exhausted by excessive and continuous withdrawal. There are many well-equipped and seemingly well-installed electric generating plants that do not deliver the current of which they are theoretically capable, and there are also many electric plants to which large additions of power have been made wherein no satisfactory results have followed, in which the failure may be due to overcrowding." It is pretty evident that the knowledge of a Louisiana civil engineer is considerably different from that of the rest of the world, and it is most kind of Mr. Golding to give his Canadian colleagues the benefit of it. It is well known how unwilling the "Britishers" are to acknowledge the immense superiority of the Great Republic upon all points and under all circumstances, but it must be sorrowfully admitted that we are quite unequal to producing anything like Mr. Golding's discovery on this side of the water.

Electrotherapeutic.—The last number of the *Lancet* contains a note by Mr. R. A. D. Daniel, M.B., formerly assistant physician at the Margaret-street Infirmary, on a case of phonic spasm successfully treated by electricity. The patient was 25 years of age, and had suffered from the complaint for over a year. It had come on gradually, and the patient described the effort to speak as being most distressing, as, though articulation proceeded, he was unable to produce any sound for an interval varying from one to two minutes. Examined with the laryngoscope nothing could be seen wrong with the vocal chords. "Under such circumstances," says Mr. Daniel, "I decided to call in the aid of electricity, and to this end used the constant current for from 15 to 20 minutes every day for a fortnight, after which time, as progress was favourable, I reduced it to three times weekly. I employed sponge electrodes of such a size and shape as could conveniently be placed on either side of the larynx, and also varied the treatment on each occasion by directing the current antero-posteriorly, placing the anodal electrode over the larynx and the cathodal one on the back of the neck. The strength of the current used varied from two to three milliamperes, and the case was treated for nearly six weeks, improvement becoming more and more apparent. It ended happily in the disappearance of the patient's malady, of which two months afterwards there had been no return." The affection described occurs so rarely that it may be mentioned that in "phonic spasm" it is the nerves governing the larynx that refuse to act, whereas in the ordinary cases of stammering it is the mechanism of articulation that is defective. There is, however, a considerable analogy between the two, and the successful treatment of the laryngeal spasm may point out a method of attacking the commoner forms of defective articulation.

The New Photography.—Prof. Röntgen's discovery, or his rediscovery, and popularisation of the anomalous radiations produced from high-vacuum discharges first noticed by Prof. Lenard has gone the round of the world, and excited such interest that it is hardly possible to look at a paper dealing in any way with scientific matter without finding mention of it, and the somewhat ghastly reproduction of the skeleton hand stares one in the face on every side. The importance of the discovery to surgical practice has been everywhere recognised, and its value in cases of bone injuries and disease, as well as foreign substances embedded in the flesh, has been put to practical test. It is evident that on this side alone there will be a demand for a suitable apparatus for producing the new radiations, and the most convenient form is a thing that it may repay the practical man to investigate. So far as can be ascertained at present, very much depends upon the quality of the glass of the vacuum tube, German glass transmitting the radiations much better than English. Also, it is most important to have a very high degree

Digitized by Google

of exhaustion. As to the minimum conditions for an effective discharge, nothing seems to be known, some of the apparatus described being, like Mr. Campbell Swinton's, excessively complicated, while other experimenters appear to have succeeded to a certain extent with simpler appliances. Prof. Murani, of Milan, has worked with a Ruhmkorff coil and 20 Bunsen cells. Using a Crookes tube of about 10cm. diameter, and having three anodes and one cathode, he obtained the Röntgen photographs with an exposure of 15 minutes. As other experimenters have succeeded with much shorter exposures, the matter is probably a question of degree. In the laboratory of Messrs. Siemens and Halske at Berlin, Dr. Neuhauss is stated to have obtained excellent results—not only with a Hittorp tube pumped empty of air, but also with the pear-shaped glass of an ordinary electric incandescent lamp. The metal wire leading to the carbon thread was used as an anode, and a metal plate outside the glass as the cathode. The glass shone with a bluish light when the current passed through it. On the other hand, Prof. Slary, of the Charlottenburg Technical Academy, has adopted a Lenard tube containing a thin aluminium plate at the part of the tube struck by the cathode rays. Such a tube is not easy to manufacture, but would be doubtless more effective.

Life of Armatures.—The *Street Railway Review* of January 15 has a long article on the care and repair of the motors of the electric tramways of the Citizens' Street Railroad at Indianapolis. The first thing noted is the constant and careful attention given to testing by Mr. H. B. Niles, the railroad's electrician. This has not only reduced the expense from armature troubles by one-half, but has accumulated a quantity of valuable information. According to Mr. Niles, there are two things which limit the electrical life of a motor armature—namely, crystallisation and breaking of wires due to jar, and weakening of the insulation due to heat. Having no cure for the former, his ideal is to make the insulation last up to the period of crystallisation setting in. At Indianapolis this period is about two years, the cars making a high daily mileage, and there being many crossings. When an armature gets old and its insulation weak, its worst enemy is found to be lightning. Indianapolis is subject to severe thunderstorms in the summer, and in order to avoid the possibility of having a large number of armatures disabled at once Mr. Niles has devised an arrester of his own. Two No. 20 single-cotton wires daubed with shellac are twisted loosely together, and one is connected to earth and the other to the trolley. The lightning easily jumps through the two cotton coverings. The current from the wire follows, but is of such volume that the No. 20 wires are melted and the circuit broken. There are six of these fuses arranged so that as soon as one is burned out the next is automatically cut into circuit. In winding armature coils—for which the Westinghouse Company's system is adopted—advantage is taken of the high insulating properties of a coating of good copal varnish. Finally, Mr. Niles has become convinced that there is now a tendency to spend too much on inspection, and that sometimes it is a case of spending £5 on inspection to save £1 on repairs. He was formerly a believer in the practice of taking motors out and thoroughly overhauling them every six weeks. This time has been lengthened by him now to six months and the general plan of inspection and repair materially changed. He reasons that if the details are looked after every night there is nothing which should require special attention in a less time than six months, that period being the life of that part of the equipment which wears out the most quickly—viz., the bearings. The electrical part of the motor has an indefinite life, and taking a motor apart every six weeks will not add to its life. When a car comes in for its regular repairs or because of any trouble it is tested for electrical faults, but otherwise it is allowed to run until trouble shows up, as it is believed that this is cheaper than spending a lot of money hunting for trouble and not finding it.

Machine Telegraphy.—Under this title, the *Journal* of the Franklin Institute contains a paper by Mr. Patrick B. Delany on a new system of automatic telegraphic transmission. The perforator has three keys giving respectively a dot, dash, and space. Dots and dashes are distinguished on the transmitting tape by the punched hole being on the upper or lower side. A positive current is sent for a dot and a negative one for a dash. The impulses therefore are of uniform duration and the line is not more heavily charged at one time than at another, and consequently the discharge is also uniform, and the signals on the receiving tape are correspondingly regular. The receiver comprises a wheel over which the chemically moistened tape is drawn under three thin iron wires which press lightly on top. The two outside wires are electrically one, and are connected to earth. The middle wire is insulated from the others, and is connected to line. When the brushes of the transmitter drop into a hole in the dot line, a positive current is sent, and a dot is marked in the track of the middle wire of the receiver. When the transmitter brushes drop into a hole in the lower or dash line of perforations, a negative current is sent, and a dot is marked in duplicate on the receiving tape, one in the track of each of the outside wires. This impulse is but a dot in duration; but as it is meant to represent a dash, it must have something to distinguish it from the dot signal; therefore, the current is forked or divided on the receiving tape, so that all dashes are in the form of double dots, while the dots proper are single, and occupy the centre line on the tape. It will be understood that the chemically moistened tape forms the circuit between the centre wire and the outer wires of the receiver, or between the line and earth; and that all positive currents come over the line and mark in the track of the middle wire, while negative currents come from the earth and mark in the track of the forked contact, forming double dots, which are recognised as dashes. In this way, no matter how bad the "tailing" may be, it is impossible to mistake a dot for a dash, or to connect them together erroneously; neither is it necessary to have definition between successive dots or dashes. The length of the composite, single, or double mark determines at once the number of distinctive marks intended. In cable signalling, there is practically no definition as to the number of impulses in the undulations of the ink line. The proportion determines. Of course, in this system of perfectly straight marks in distinctly different lines, translation is much easier. When reading the paper before the society Mr. Delany made several experimental transmissions through an artificial line of 800 ohms resistance and two microfarads capacity, or the equivalent of an ordinary iron telegraph wire between New York and Philadelphia. Perfectly legible records were obtained at a speed of 1,200, 1,800, and, finally, 2,400 words per minute.

Motorcarts on the Reads.—In spite of the practical certainty that the prohibition of motor carriages on the common roads is to be repealed as soon as Parliament meets, the position of the experimenter in this kind of vehicle is still full of peril. Last week, at Tonbridge, Mr. Walter Arnold appeared before the local magistrates to answer four summonses for not working a horseless carriage according to the regulations of the Locomotives Act. Mr.

Digitized by Google

Arnold urged that the Local Government Board admitted that the Locomotives Act was not intended to include such vehicles as these horseless carriages, and that the mistake would soon be remedied, but the chairman said it was not for the magistrates to enquire into future legislation, and under the present legislation they must convict. The defendant would be fined 5s. and £2. 11s. costs on the first and 1s. and 9s. costs on each of the other summonses. In reference to this case, Mr. Andw. W. Barr, hon. secretary of the Self-Propelled Traffic Association, at the request of the president of the association (Sir David Salomons, Bart.), calls attention to the issue of four summonses for one breach of the law. This is a matter which he considers calls for the attention of the Home Secretary, who should quash all the convictions but one. It may be noticed that in a similar case at Glasgow the police magistrate, after taking a week to consider the points raised, decided that he must convict, but that a half-crown fine would be sufficient. At Solihull a shilling fine has been imposed. There appears, however, to be less danger from the local police in Scotland than in England, for Mr. T. R. B. Elliot has not only made a successful run in a horseless carriage from Clifton Park, Kelso, to Ladykirk and back, a total distance of between 40 and 50 miles, but has allowed it to be recorded in the local Press, and so far he has escaped with impunity. Meanwhile, the Coventry Town Council have passed a resolution: "That a memorial to the Board of Trade be prepared, and signed by the Mayor in the name and on behalf of this Council, praying that a bill may be brought in to relax the restrictions which now hamper the transit of mechanically-propelled vehicles along the public roads." "If," said Mr. Kimber, the seconder of the resolution, "the Council could do anything to extend trade and commerce in the country, and Coventry in particular, it was their duty to do so." This is putting the matter into a nutshell. At Sheffield they have also an eye to progress in this direction, and there is to be a competition and exhibition of motor vehicles at Owlerton in the forthcoming spring. So far, however, as electric cars are concerned, it is to the Geneva Exhibition this year that we must look, and possibly the object lessons to be given there may extend considerably the ideas now held as to the possible facilities of street locomotion, and supply illustrations of readier uses of electricity. As the River Rhone is utilised to supply 12,000 h.p. to be electrically transmitted six miles to the grounds of the exhibition, elaborate electrical works can be shown, and there will be horseless cabs, driven by electricity, as well as many other appliances. It is stated that in France the new vehicles have been looked upon already with sufficient favour to encourage the starting of a company to put horseless carriages on the streets of Paris to take the place of the ordinary cab, at existing fares, and subject to the usual police regulations.

Rentgen's Radiations.—As regards further discoveries of the properties of the new radiations, little has been done during the past fortnight beyond repeating and verifying the original results. The radiations are not refracted by any medium that has been tried up to the present, though Prof. Röntgen is inclined to suspect a very small deviation by prisms of ebonite or aluminium. The relative opacity of the heavy metals prevented experiments in this direction giving any results. The rays have a tendency to spread out from the direction of propagation. This may be due to diffraction, but no interference fringes have been obtained, so that nothing is known as to the length of the wave, or even if there is a wave. As the vibrations would probably be of various periods, this is not otherwise than what might be expected. The only thing certainly ascertained appears to be that the opacity of substances to the new radiations corresponds closely to the density, but whether the two are directly proportional is not clear. Some experiments with thin metallic plates go against the supposition, but as there is probably some effect analogous to reflection at the surfaces, which must be allowed for, these are not conclusive on the point. On the other hand, it seems to make little difference whether the substance is solid or in powder, which goes against the supposition that there is either much reflection or refraction. No certain conclusion has been come to as to what place the radiations are to be assigned in the theory of light. It is probable that further facts must be awaited before much will be determined on this point. The first thing is clearly to distinguish between the Röntgen rays and the cathode rays. The latter are almost certainly molecular, since they are deflected by a magnet, and are only transmissible in a vacuum or a highly exhausted gas, since, though Prof. Lenard believed that he had got them out of the Crookes tube, they could not be propagated beyond a very short distance in air. The properties of the Röntgen rays are quite different, and resemble more closely those of ordinary light. Prof. Lodge, lecturing at University College, Liverpool, has referred to the possibility that the rays were ultra-violet light, high up in the scale of the spectrum. If so, it was probable, judging from their effects, that the rapidity of their vibration was a million times greater than that of ordinary light, or about as much more rapid than light as light was more rapid than sound. There was some evidence in favour of this, since the rays were able to diselectrify negatively-charged bodies. At present, however, he felt inclined to adopt the more sensational theory, that those rays were longitudinal waves in the ether. If so, the discovery would open up a department of physics as large as light, sound, or electricity. Prof. Schuster, referring to a corpuscular hypothesis, pointed out the fact of Newton having held that fine particles of light could pass through opaque substances. Light and sound were transmitted with differing speed through varying substances; but here, however, were rays which seemed to go at almost the same speed through everything, and which were not acted upon by a lens. There was a feeling on the part of physicists that in these rays we were on the eve of a discovery of something which would link the hitherto isolated force of gravity with that of the higher forces of nature. The general opinion on the Continent appears to be in favour of the longitudinal vibration theory. In that case, instead of adopting with Prof. Lodge an enormously rapid vibration, we are compelled to assume an excessively great velocity compared with ordinary light. It would not greatly trouble the mathematicians to modify the Maxwell equations so as to admit of longitudinal vibrations. Indeed, they would be rather pleased to do so, but there is a practical difficulty in that without an incompressible ether it does not seem possible to avoid setting up longitudinal vibrations whenever light is reflected at an angle. But these have been looked for and not found. It would be going too far to invent a medium in which these were produced and subsequently converted into transverse vibrations, though this would account for the "spreading" effect observed. Neither does it seem necessary to assume that the action on the photographic plate is indirect through the medium of a fluorescence of the glass back. If the rays—whatever they may be—are capable of exciting a vibration of a non-concordant period in the molecules or atoms of the glass, they may be considered quite capable of upsetting such an unstable system as the molecule of the silver salt.

LECTURE XXIII.

(Specially Contributed.)

We have found when examining magnetic phenomena that, when a small piece of iron is brought into a magnetic field it acts so as to lessen the resistance of the magnetic circuit. The iron filings which we use to show the direction of the lines of force show us also what larger pieces of iron—say, iron wires—would do if they were flexible: they would bend round to make contact with each pole. The action between the opposing surfaces of a condenser is similar. The tendency is to shorten the air-space between the opposing conductive surfaces, and thus if one surface is fixed and the other movable, the latter will tend to move towards the former; and this tendency to motion can be measured. The tendency to motion depends upon the difference of electrical pressure, or the voltage, acting between the two opposed surfaces. A mechanical analogy often used to try to explain the electrical action between condenser plates is to suppose the two opposed surfaces connected by means of an immense number of very fine parallel threads. Any two bodies so connected would be drawn together if a twist was imparted to the threads. The greater the twist the greater would be the pull, and so it would be possible to measure that twist by measuring the pull. Now imagine that the opposed surfaces of a condenser are joined by a dielectric, and that the action of the electric pressure is to twist the dielectric; the twist can be made greater and greater by the application of greater and greater pressure till the stress becomes too great and a spark passes—that is, till the insulation breaks down. A very careful examination of the phenomena of static electricity has led most scientific men to the conclusion that the action in these cases takes place wholly within the dielectric or insulating medium, or the medium between the opposed conducting surfaces. Without entering further into this question, we may then take it as certain that when two conducting surfaces are opposed in the manner indicated, and one surface is fixed and the other movable, the tendency of the latter will be to approach the former when the two are under a difference of electrical pressure, and the measurement of that tendency will enable us to obtain the measurement of the difference of pressure—that is, the measure of the voltage acting to produce the pull.

Thomson's Electrostatic Voltmeters.—Lord Kelvin (then Sir W. Thomson) has given us a number of admirable instruments of the electrostatic type. His multicellular and vertical voltmeters will now be described. The multicellular voltmeters are made on the principle of an air condenser. They are intended to measure from 40 volts to 1,600 volts. One instrument has a range from 40 to 160 volts, another from 80 to 240, another from 500 to 1,600, and so on. In this multicellular instrument we have the two sets of conducting surfaces; these are shown in the section (Fig. 1). One set is movable about an axis. The motion increases or decreases the area of the opposed surfaces, and so increases or decreases the capacity of the condenser. The condenser is enclosed in a metal case for the double purpose of protecting the movable part from air currents, and from the disturbing influence of any electrified body other than the fixed portion differing from it in potential. In all the instruments the fixed portions consist of two sets of quadrant-shaped cells in metallic connection with each other, and formed by a number of parallel brass plates. These cells are fixed by an insulating support to the case of the instrument, and a terminal passes from them to an insulated binding screw on the outside of the case. The movable portion in all the instruments is in metallic connection with the surrounding case. In the multicellular voltmeters this connection is made through the suspending wire, and in the vertical-scale voltmeter and electrostatic balance through the knife-edges which support the movable part. The movable portion carries the pointer, which indicates by direct readings the difference of potential between the two parts of the condenser.

The action of the instrument, shortly stated, is as follows. When the fixed and movable plates are connected respectively to two points of an electric circuit between which there exists a difference of potential, the movable plate tends to move so as to augment the electrostatic capacity of the instrument, and the magnitude of the force concerned in any case is proportional to the square of the difference of potential by which it is produced.

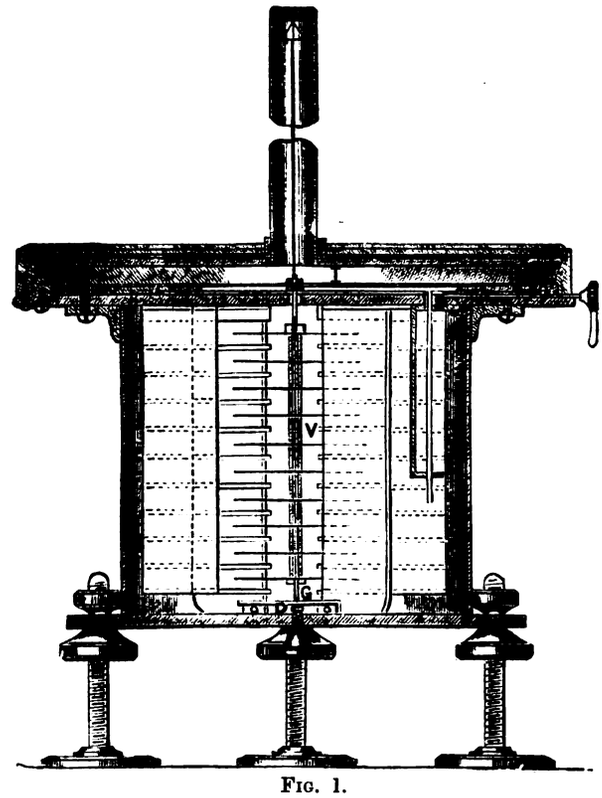

FIG. 1.

In the use of the vertical and electrostatic balance instruments this force of attraction is balanced by the horizontal components of a weight of any convenient amount being hung on the knife-edge in connection with the movable part, while in the case of the multicellular it is balanced by the torsion of the suspending wire. The arrangement of the parts of the multicellular electrostatic voltmeter is shown in Figs. 1 and 2. These figures apply

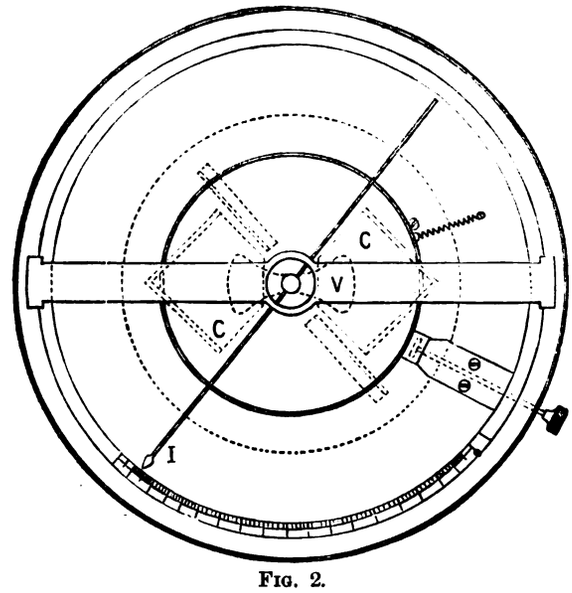

FIG. 2.

to an early form of the instrument, and differ in two matters of detail from the voltmeter as now made. For simplicity in manufacture, the cells are now made with straight backs, and the plates looked at in the plan are, therefore, triangular instead of square. A coach spring has now been interposed between the suspending wire and the spindle carrying the vanes, as explained below.

The insulated cells are formed of triangular brass plates

Digitized by Google

fixed into sawcuts in a brass back piece, so as to be equal distances apart and accurately parallel to each other. Two sets of these cells, C, are fixed relatively to each other, as shown in Fig. 2, by a vulcanite support to the sole-plate, so that their plates are horizontal, and are completely enclosed within the brass cylindrical case of the instrument. On the top of this cylinder is a shallow

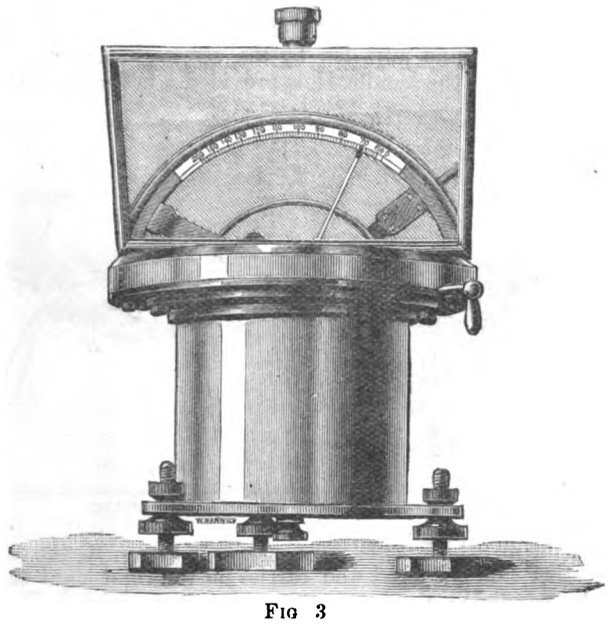

Fig 3

horizontal circular scale-box containing the scale of the instrument, and having a glass cover, which serves to protect from currents of air the movable indicator, I, and the scale and interior parts from dust. For the movable part, a number of vanes, V, similar in form to those of the quadrant electrometer are used. These vanes

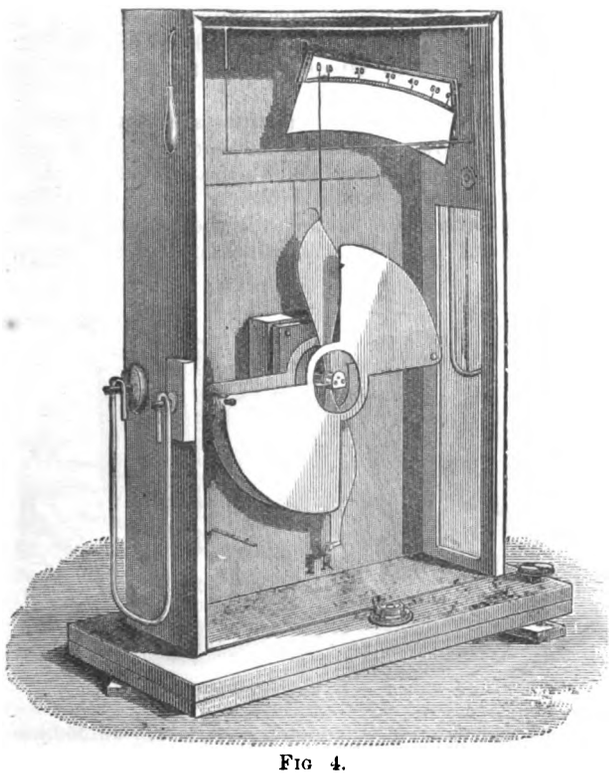

Fig 4.

are placed parallel to each other on a spindle with distance-pieces between them. The top end of this spindle passes through a small hole in the sole-plate of the instrument, which forms the bottom of the scale-box, and is attached to a small coach spring, which in turn is secured to one end of a fine iridio-platinum wire suspended from a torsion head at the top of a vertical brass tube. The coach spring has sufficient resilience to allow the spindle to touch a guard-stop, and so saves the suspension from injury in event of the instrument being roughly set down.

Two vertical brass repelling plates, which also act as guard-plates to prevent the movable part from turning beyond its prescribed limits, are fixed to the bottom of the sole-plate. These two plates carry a guide-plate, G, with a circular opening in it, through which the lower end of the spindle passes. A little brass disc, or head, D, is attached to the end of the spindle, sufficiently large to prevent its passing back through the hole in the guide-plate. Thus the moving part is effectually secured from swinging about so as to be injured, and by no possibility can it come into contact with the insulated quadrants. When the instrument is level the spindle hangs free by the suspending wire so that the vanes are horizontal, and each is in a plane exactly midway between those of two contiguous condenser plates. An aluminium needle attached to the top of the spindle indicates on the horizontal circular scale fixed to the upper side of the sole-plate the difference of potential between the movable and fixed portions of the condenser by direct readings in volts.

To enable the multicellular to be used as an inspectional instrument capable of being read from a distance, as across an engine-room, a mirror supported in a frame which passes over the vertical brass tube, and rests upon the glass cover of the instrument, is supplied. When this mirror is in position it is at an angle of 45deg. with the plane of the sole-plate, and by reflecting the scale and pointer gives the instrument all the advantages of a vertical scale. The instrument is shown in Fig. 3, with its mirror in position. A small thumbscrew is placed in the centre of the base-plate below the instrument, which can be screwed in so as to lift the weight of the spindle and vanes from the suspending wire and clamp the disc on the end of the spindle against the guide-plate. A switch is attached to the upper terminal of the instrument by which the voltmeter can be taken out of circuit when desired. The switch, after breaking circuit, puts the case and the insulated cells in metallic connection. The scale is graduated to read directly in volts.

The vertical electrostatic voltmeter is shown in Fig. 4, and, as will be seen, the insulated quadrants are supported with their plates vertical, and only one large vane is used. This movable plate is supported in a vertical position on knife-edges, so that the plane of its motion is parallel to the two fixed plates which form the insulated quadrants. Its upper end has a fine prolongation, which serves as a pointer for indicating the deflections on the scale of the instrument, and at its lower end is fixed the knife-edge for the weights, having its length perpendicular to the plane in which the plate moves.

In order to save time in taking readings, an arrangement is provided for checking the oscillations of the movable plate, and stops are placed to limit its range and prevent damage to the pointer. One of these stops, the left-hand one, is made to act as a support for the vane in the arrangement for portability described below.

The scale is graduated from 0 to 60, and the divisions represent equal difference of potential, the actual magnitude of the difference per division being dependent upon the weight in use at the time. A set of three weights is sent with each instrument, providing for three grades of measurement in the proportion of 1 : 2 : 4. Thus the instrument shows one division per 50 volts with the link (the lightest weight) alone on ; one division per 100 volts with the medium weight hanging on the link, and one division per 200 volts with all three weights on.

Ayrton and Mather's Electrostatic Voltmeter.—In this instrument both the fixed and movable conductors consist of concentric cylindrical segments. Fig. 5 shows A B C connected by D, the brass fixed conductors ; the movable segments, F E, of aluminium, rotating on the spindle, S, on which is also the pointer, P, with its counter-weight, W, to keep it at zero when no current is passing. The movable segments are carried by light aluminium frames, and are free to move within the air-space between the fixed segments. The apparatus is a modified condenser, as, indeed, these electrostatic instruments must be, one face of the enlarged conductor upon which accumulation takes place being rigidly fixed, the other conductor being movable.

Digitized by Google

Kenelly's Voltmeter.—This is a variation of the above instrument. In it, the vertical concentric segments, A A, are of brass, connected through the frame at the bottom. Into the grooves of these segments are placed aluminium segments fixed underneath the vane, V. This vane also carries a pointer, P (Fig. 6). The system of vane and segments is carried by a bifilar suspension, C, and is through this suspension electrically connected to one of the points in the circuit.

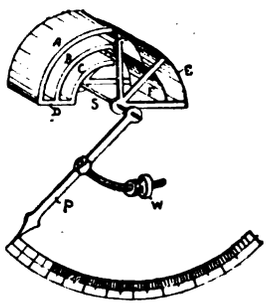

FIG. 5.

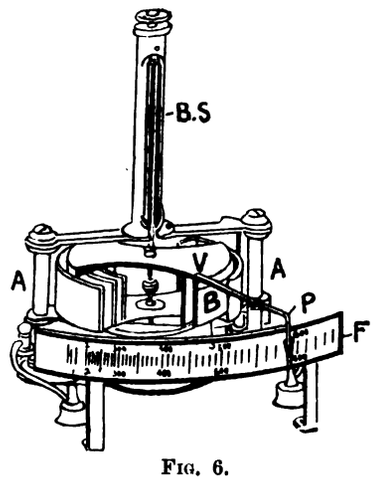

FIG. 6.

The brass segments can be electrically connected to the other point in the circuit through the frame of the instrument. "The electrostatic attraction set up between A and B causes the segments, B, to enter the grooves between the plates, A, thereby twisting the suspension wires till balanced by the torsional force of the twisted wire. Then the position of the index of the pointer upon the direct-reading scale gives the electrical pressure between the two sides of the circuit." To avoid sparking, the walls of the grooves are heavily lacquered, so that contact with the needle segments allows no sparks to pass.

ZERENER'S METHOD OF ELECTRICAL CASTING, WELDING, AND SOLDERING.*

Welding and soldering by electricity has of late years, and especially since the publication of the Elihu Thomson patent in 1886, attracted the attention of a number of professional men. There are now four systems in use—viz., those of Thomson, Benardos-Slavianoff, Zerener and Lagrange-Hoho. Each distinctly differs from the others in principle.

The actual introduction of Zerener's method into several of the larger establishments of the iron industry, enables us to fully report on it and on the latest type of apparatus employed. Mr. Zerener, as the outcome of a long series of experiments and arduous trials, states that if the magnetic lines of force of a horseshoe magnet and the lines of the electric arc cross each other horizontally and rectangularly in a plane, the arc becomes vertically diverted to this plane and resembles a blow-pipe flame. He characterises, therefore, his welding and soldering apparatus in combination with the winding of the horseshoe magnet as contrivances for producing a blow-pipe flame from the arc between two carbons. The arc is placed in such a way in a magnetic field—formed by two magnetic poles opposite each other in position—that the magnetic and electric lines of force, as before mentioned, cross each other. It may here be mentioned that it is important for practical purposes that the flame should be steady. To ensure this, due regard must be paid, not only to the quality of the carbons, but also to the combination of the solid and cored carbon rods. A special kind of core, or the passing of gaseous or solid substances through an axial bore of the carbons, may also at times be advantageous. It is essential that the carbons should be of very hard quality.

We show in Fig. 1 an apparatus for hard soldering, which is simple and light. The tube, *o*, which is fixed in a wooden handle, H, and bent, carries immediately behind the first bend a rectangular body, C^1, of non-conducting material. This holds a brass tube to guide a round rod, S^1, provided with groove, which can be moved up and down, and which carries the carbon-holder, K^1. The corresponding insulating body, C, serving the same purpose, is pivoted at the joint, *g*, and connected with the end of tube, *o*. The rods, S and S^1, are kept in place and adjusted by the screws, *s* and s^1. On the left side of the handle, H, is provided a bell-crank lever,

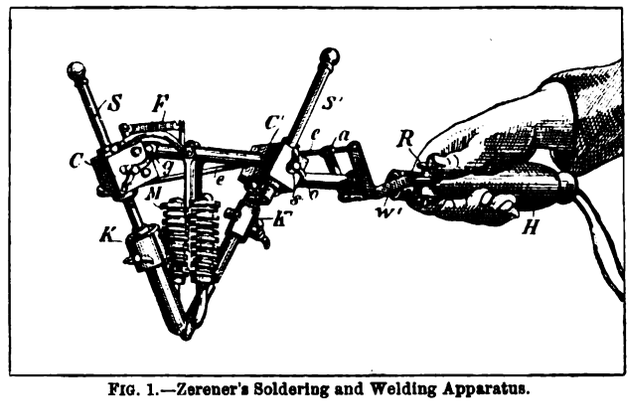

FIG. 1.—Zerener's Soldering and Welding Apparatus.

one side of which, *w*, is governed by a screw, R, whereas the other side is curved and carries on the right-hand side of the handle, at *a*, a thin connecting rod, *e*, which leads to the insulating piece, C, and can move the same. It thus causes the carbon in the holder, K, to approach the other carbon and to touch it at the point. The spring, F, tends to produce a movement in the opposite direction of the movable piece, C. The workman therefore has to turn the regulating screw, R, with his thumb to either the right or the left, according as he wishes to press the lever down or lift it up, in order to move the carbons together or to separate them. These apparatus require, according to the melting point of the respective materials to be soldered, a current of from 18 to 50 amperes with about 65 volts pressure.

The details of a larger apparatus are reproduced in Fig. 2. The apparatus, which is suspended over the work, can be moved in a horizontal and vertical direction, and is guided by means of a handle, protected from the radiant heat by sheet iron; also in this case the relative positions of the carbons and the magnetic poles are altered.

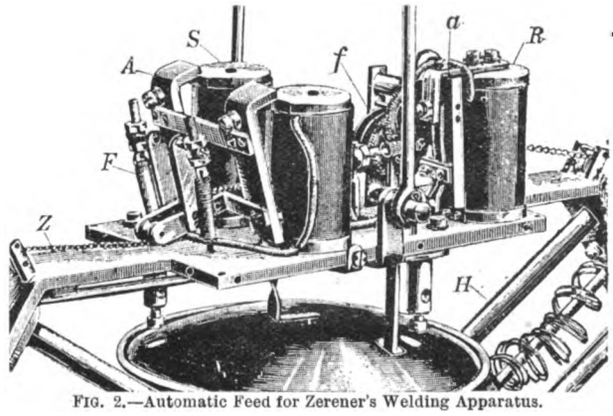

FIG. 2.—Automatic Feed for Zerener's Welding Apparatus.

The two parts, S and S^1, which carry the carbon-holders, are brought against one another through pulleys, F F^1, between the parallel-motion rods, *u* and *h*, under an obtuse angle, in such way that the point of the negative carbon comes always to be below the crater of the positive carbon. A chain, T, running over pulleys connects the movable holders with the regulating mechanism, which is placed above the triangular frame and the heat reflector, W. This regulating mechanism may vary in construction, but has to deviate so far, more or less, from that of an arc lamp, as the use of much stronger currents has to be taken into consideration, and likewise the effects of a very high degree of radiant heat. The regulating mechanism (Fig. 2)

* From the *Elektrotechnische Zeitschrift*.

Digitized by Google

is therefore placed in comparatively high position, besides being protected by a heat reflector of German silver. The illustration shows mainly the angular frame-plate, with the commutator, R, mounted upon it, which latter effects the feeding of the carbon, and, further, the shunt arrangement, S, which, at the start, has to form the arc, and has also partly to maintain it. The slight alteration in the sliding contrivance of the carbon-holders which is shown can be entirely ignored. The commutator, R, is formed by an electromagnet in the shunt, before which an armature, *a*, provided with a cut-out, when a certain pressure is exceeded, oscillates under the influence of the spring, F, thus causing a ratchet wheel to rotate, and likewise, by means of gearing, part of a shaft revolve. The wheel is on the same axle as a pair of pulleys, with which it is connected by friction. The pulleys can be moved to and fro independent from the clockwork with which they are connected by a key on the extended shaft, which can be seen projecting in Fig. 2. Over these pulleys is the chain, T, which at this point is marked Z. The second part, S, of the regulating mechanism consists of a pair of electromagnets, in front of which are placed the armatures, A, bent at the top. To these is fixed a lever carrying two little pulleys. Two springs, F, work against the attracting power of the magnets The chain, Z, being placed over the pulleys, as shown in the sketch, the free end of it, Z^1, moves upwards and downwards with the carriage of the carbon-holders, according to the action of the armatures, A.

These self-regulating apparatus are also made for various strengths of current of from 35 to 250 amperes, and, as mentioned before, varying in construction. Special protection against the strong light and the radiant heat is naturally provided for. Zerener's spectacles may be mentioned here as well adapted for the purpose. The lower half of the glasses is of such colour that the eye can see through it straight into the welding flame without any harm to the sight, whereas the upper half is of such peculiar tint that even by ordinary daylight the work can be seen in all its details.

Zerener's apparatus are constructed and adapted for a great variety of work, and it is evident that injury to the metal can be entirely avoided by the possibility of employing the source of heat at any desired distance from the object to be worked upon, which is impossible when the latter itself, serving as electrode, is exposed to a heat of several thousand degrees. Another advantage is the possibility of regulating the heat effect of the arc. Such apparatus can be employed wherever there is a dynamo machine going, and will be found extremely useful for repairs to engines and machinery without taking them to pieces.

THE ELECTROLYTIC PRODUCTION OF CAUSTIC SODA AND BLEACH.

Step by step, with steady onward strides, electricity is establishing its position as the handmaid of our great industries. Amongst its numerous applications to industrial purposes, the latest, and by no means least, important is that of the commercial production of caustic soda and bleach. Not that this has been accomplished at one heat, so to speak; it has been the work of time and of many brains. Numerous attempts have been made to attain the coveted end, but until now the reward of practical commercial success has been withheld from those who strove hard to achieve it, and who both desired and deserved it. The history of the development of the question is a long one, too long to be entered upon here, suffice it to say that, as far as we are aware, it commenced with the introduction of the Gramme machine into this country some 23 years ago. Since that time many earnest workers have taken it up, and each has advanced it a stage until to-day finds the process perfected.

The system under notice is that patented by Colonel T. J. Holland and Mr. James C. Richardson, and which was first put in practical operation a few years since at a large paper mill at Snodland, Kent. There it was developed on a practical manufacturing scale until it attained the stage of commercial maturity. When it was demonstrated that caustic soda and bleaching powder could be expeditiously and economically produced by the decomposition of salt by an electric current, it was determined to carry on the manufacture at independent works. These were found at St. Helens, Lancashire, the situation having been selected as most convenient both for obtaining the raw materials and for disposing of the manufactured goods.

The works are situated on 15 acres of land, which gives ample room for extensions. They are intersected by lines of railway, with a siding on the North-Western system, and have a wharf on the St. Helens and Mersey Canal. The rock salt, which is obtained from Cheshire, is first dissolved in water under agitation, the brine being run off into settling-tanks, from which it is pumped up to the store-tank for the supply of the decomposing-tanks. There are 200 of these tanks, disposed in 10 sets of 20, placed tier upon tier, and surrounded by galleries at three different levels. The tanks, which are 20ft. long, are divided into 32 cells, half of these being for the anodes, and the remainder for the cathodes. The anodes are composed of pieces of gas-retort carbon set in lead or antimony backs, the cathodes being cast-iron grids. The anodes are placed in cells, which are closed in at the upper part, but open at the lower, to admit the inflow of brine. The chlorine gas which is given off at the anodes passes through closed conduits from the cells to a main leading to the bleach-chambers. The hydrogen gas given off from the cathodes escapes harmlessly into the air. Means are provided for feeding common salt into the cathode cells, in order to maintain the normal strength of the solution of caustic soda, which is run off at intervals and stored in a large tank in the caustic-shed.

We have now the two resultants of decomposition—chlorine gas and caustic soda. The gas, being heavy, is exhausted from the cells and driven into the bleach-chambers, of which there are three, each of about 12,000 cubic feet capacity. Here the gas is absorbed into the lime (which is obtained from Buxton and prepared on the works), and the bleaching powder of commerce is formed. From the stone tank in the caustic-house the solution is run into the caustic-pots, of which there are nine each of 12 tons capacity. In these the liquor is evaporated down to the required density, after which it is filled into drums for the market.

The current, which is the prime agent in the manufacture, is generated by two of Parsons's parallel-flow steam turbo-dynamos at 120 volts, each generator being capable of giving off 110 units. On the switchboard are two Weston ammeters for 4,000 amperes each and a Weston voltmeter, besides which there are 10 other ammeters for the circuits. Two horizontal brass bars run the whole length of the board at the back and 10 vertical bars in front, connection being made with massive copper plugs which put the tanks and instruments in circuit. Five cables leave each side of the board to go to each side of the tank-house. All cables used are of bare copper, including those which connect the switchboard with the dynamos, which are buried and covered with pitch. The alternate compartments of the decomposing-tanks are closed with a lid from which the carbon anode is suspended; the tanks are placed in series with each other, the cells being in parallel. There are five circuits on each side of the tank-house, each circuit making a set. Each tank requires about four or five volts to send 700 amperes through it. The connection of the main cable is effected in a very ingenious manner, which, in common with the other details of the process, forms the subject of a patent. The cable is of stranded copper, and at each terminal one strand is taken off to join on to it, and so on to the second, where another strand is joined on, the cable thus getting smaller and smaller until the last strand is taken off to the last terminal, a considerable saving in copper thus being effected.

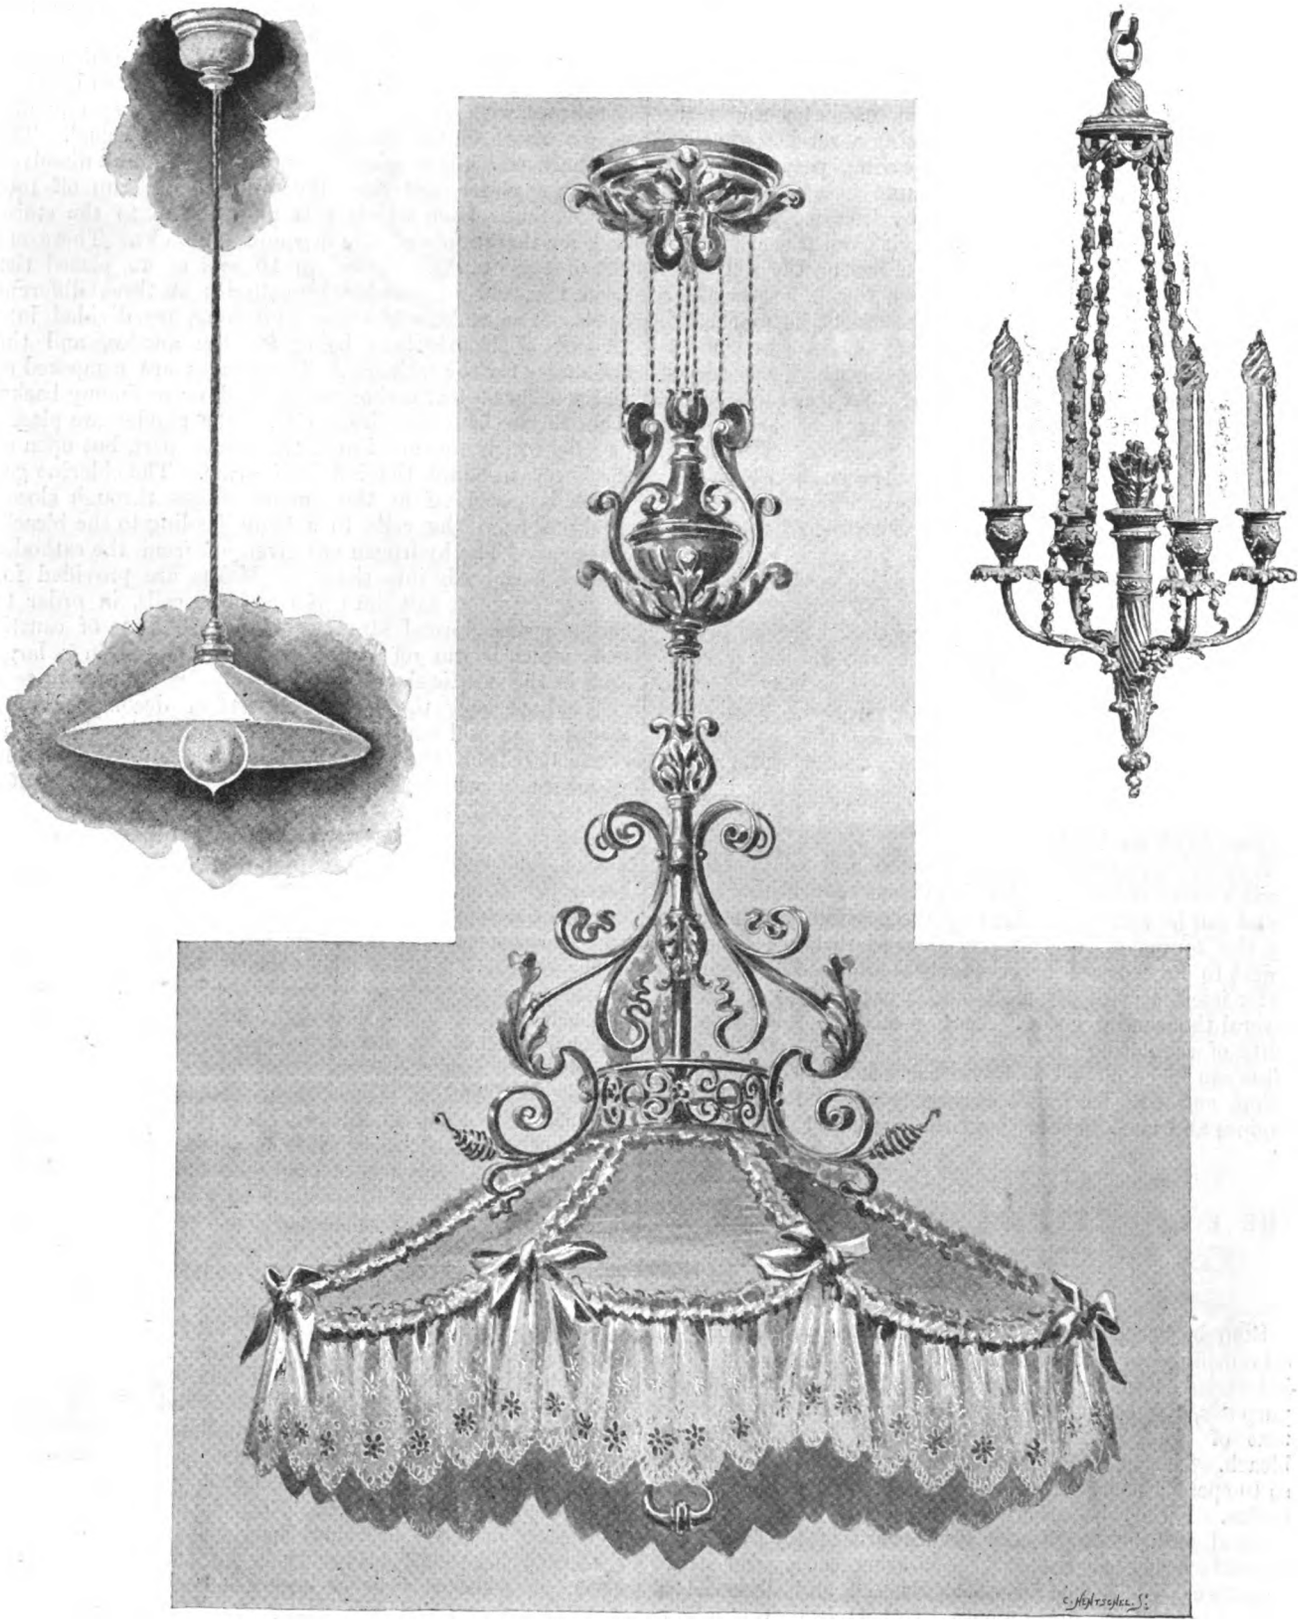
The present output of the works is about 100 tons of 35 per cent. bleaching powder and 60 tons of 70 per cent. white caustic soda per week from 60 tons of common salt. This is produced by the plant and apparatus we have described, which we recently were afforded the opportunity of inspecting, and with which we were much pleased.

Digitized by Google

That the products were of the highest quality was shown by their appearance, and was further manifested by the business which was being done as shown by the order-book. The business, moreover, is steadily increasing, so that arrangements have been made and plant and machinery ordered to treble the present production. The extended works are to be in operation this summer, and it is anticipated that they will have to be further increased to meet the growing demand for electrolytic alkali. Altogether the Electro-Chemical Company's works at St. Helens present a practical and highly satisfactory solution to the problem of the electrolytic production of caustic soda and bleach from common salt, and their success constitutes another triumph of electrical science.

NEW LIFE.

Few buildings once used for electrical enterprises have been abandoned to other uses due to failure. We are glad, therefore, to see that the old premises of Messrs. Woodhouse and Rawson, in Cannon-street, have been taken by the General Electric Company. These premises, of which the new entrance is in 88, Queen Victoria-street, were large enough for the old firm in their most prosperous days, and yet the General Electric Company are now using them for their fitting department only. The alterations, now practically completed, have converted these premises into the most convenient and extensive showrooms for electroliers



The General Electric Company's Fittings.

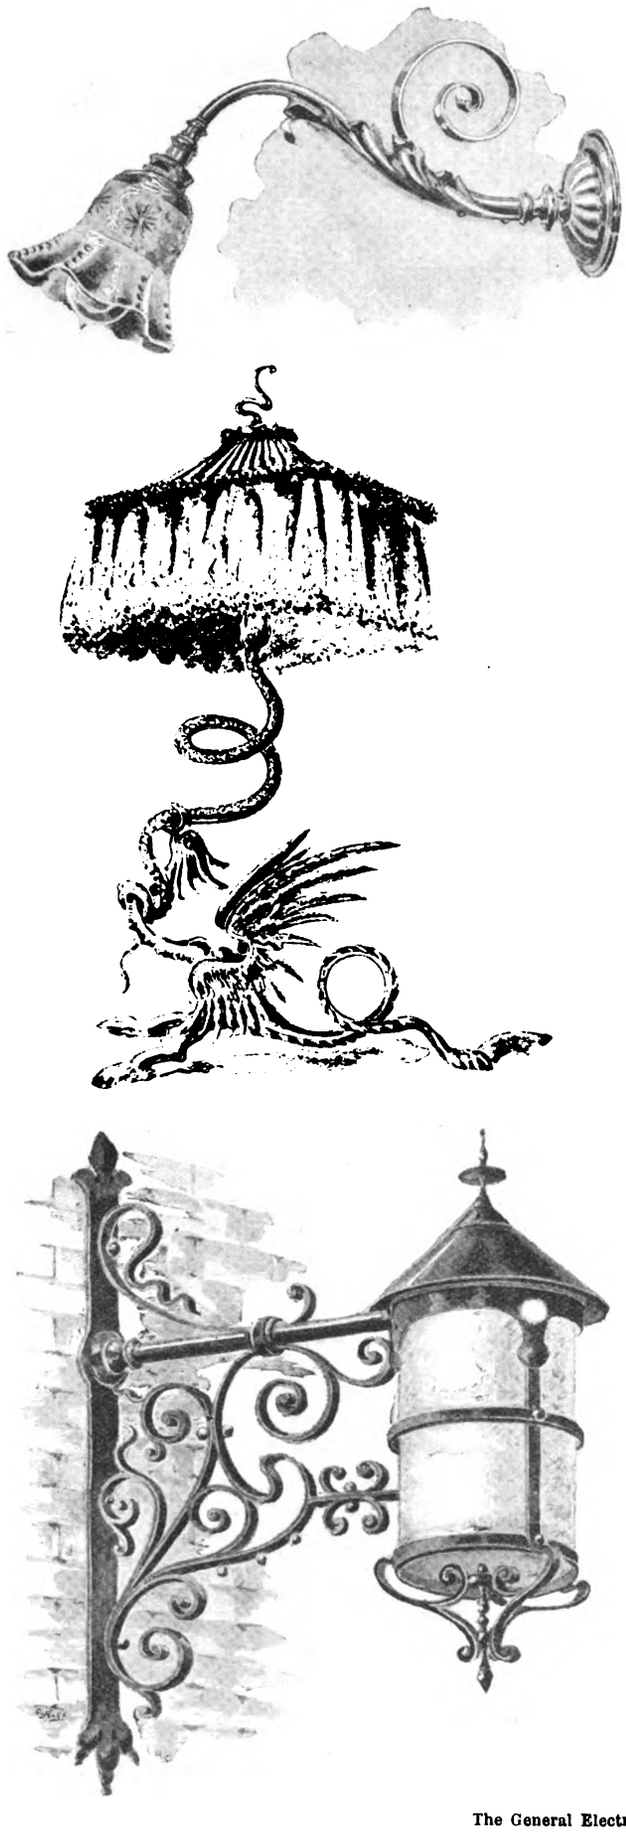
The Genera Electric Company's Fittings.

and electric fittings in the kingdom. Entering from Queen Victoria-street, the room just inside the lobby is used as an accessories department, where such necessary details as galleries, adapters, holders, cord grips, cord ornaments,

Digitized by Google

back-plates, etc., are stocked. The whole of the rest of the ground-floor forms one large showroom. This spacious department is decorated with taste, the walls being panelled and upholstered with dark-brown cloth. The panelling is also relieved with gold moulding. The ceiling is painted a terra-cotta colour and relieved with gold panelling. Dealing with the walls first, the fittings attached to the panels are arranged in accordance with the position in the company's new catalogue. This gives great facilities for identification. Every fitting is wired, and can be lighted by means of plugs and switches at the base of the panels. The fittings can thus be seen complete with lamps and shades, and as the common showroom fault of overcrowding has been avoided, a good idea of the general appearance of each article can be obtained. The whole of the ceiling is wired in two main circuits, so arranged and sub-divided that adjacent electroliers come on opposite sides of the three-wire system. This renders an equal division of the load on the main more probable. The plug and switch system on the ceiling is somewhat similar to that on the panels. The switches controlling the lights are conveniently placed in accessible positions on the walls. Two large iron columns supporting the building are the cause of a pleasing effect in the middle of the room. These columns have been encased with octangular wood panelling relieved with gold, and a series of steps at the base are used to display the small bronze pedestal fittings, etc. The floor space, which is most ample, is hence not cumbered by the usual collection of miscellaneous fittings liable to fall at the touch. The old entrance from Cannon-street is permanently closed, and the space in the lobby is used to display the various shades and glassware stocked.



The General Electric Company's Fittings.

This showroom is used entirely for the usual run of commercial goods, and these are everywhere arranged so

Digitized by Google

that comparisons between certain fittings of a given class can be easily made. Thus all the common types of single-light pendants and shades are placed together. The artistic fittings on view are too numerous for individual mention, but the illustrations given herewith will enable the reader to form an idea of the range covered. One adjustable pendant fitting with silk shade, for dining-room purposes, which has additional lamps attached to the counter-weight for lighting the room, is worthy of individual note.

Going up to the second floor, the special fittings are on view in a room specially constructed for the purpose. A well 12ft. diameter under a skylight has been fitted with a handsome dome of blue silk plush, surmounted by a canopy of silk. The scheme of colour throughout this showroom is the rich blue always found in the decorations of the Louis periods. The upholstering in this colour is relieved with cream panelling lined with gold. The fittings shown here include examples of all the different Louis styles, as well as examples of the Renaissance and Gothic types of decoration. A number of real and original bronzes, by noted authors, are also on view which are adapted for electric pedestals and hall-lighting ornaments. Small statuary, also arranged to carry small candle and flame lamps, are also shown on the tables in this showroom.

The rest of the space on this floor is used for the designing and drawing department. The second and third floors are used as stock-rooms, and the spacious basements hold the stock of glass shades, etc. These new premises, and the goods they contain, are well worthy of a visit from an electrical engineer.

ALTERNATE-CURRENT TRANSFORMERS.

BY DR. J. A. FLEMING, F.R.S.

Dr. Fleming delivered his third Cantor lecture on the above subject at the Society of Arts on Monday last. The lecture was commenced by a short description of the proposed units of magnetic induction. Dr. Fleming threw on the screen the statement of the relations of the weber to other physical quantities. Thus, if one turn of conductor having a resistance of one ohm is linked or unlinked with a magnetic field of one weber, one coulomb of electricity is produced. An experimental determination of the magnetic field between the poles of a permanent horseshoe magnet was then made by means of a ballistic galvanometer previously calibrated by a condenser discharge. The formula, in more convenient units, reads thus: microwebers × linkages = microcoulombs × ohms. The lecturer then went on to consider magnetomotive force, which equals $\frac{4\pi\alpha\tau}{10\ l}$ where α = the amperes in the coil of τ turns, and l = the length of the magnetic circuit in centimetres. A useful approximation is the statement that the magnetomotive force equals the ampere-turns per ½in. of circuit. Returning to the question of hysteresis and the different qualities of iron, Dr. Fleming described the iron-testers invented by Prof. Ewing, one of which was on view.

Referring to the influence of the form of the transformer on the shape hysteresis curve, two such examples were shown. The one was obtained on an old Ganz transformer in which the lozenge crosses the vertical lines at a considerable angle; the other, from a Westinghouse transformer, is nearly vertical. The alteration in the angle was shown to depend on the power factor of the transformer in question. Various constants for the hysteresis formulæ given last week depending on the quality of the iron used were then given before the lecturer went on to the question of the methods of testing transformers.

He passed over the well-known three-ammeter and the voltmeter methods of measuring power as too cumbersome and too liable to error for regular use. The voltmeter methods were then discussed, and Dr. Fleming referred to the necessity of keeping the construction of the instruments free from metal parts. The old story of the errors caused by metal cases was referred to, and an interesting experiment showed the effect of the eddy-current reaction on a suspended coil carrying an alternating current when a metallic plate was brought near it. It was also stated that even concentric coils of wire might appreciably alter the readings of an instrument. Hence care should be taken when using a Siemens dynamometer, as the idle coil, although on open circuit, has often an appreciable effect.

Dr. Fleming's non-inductive resistances were exhibited and explained, as were a number of practical details of the best methods of testing transformers. Where a subsidiary transformer is used to supply the shunt coils of the wattmeter, the lecturer stated that it should be only lightly loaded to ensure accurate results. Dr. Sumpner's differential method of testing large transformers was also explained, and the fact that the hysteresis loss decreases with the rise of temperature was referred to.

THE CONSULTANT'S CONFESSION.

I am the greatest consulting engineer
Because I solely consult—
My own interests.
I am he who must be obeyed,
He! he!
My word is law,
Good law!
Before my personality
Contractors quail
And vail.
I have unbounded faith in the reality of matter
And in my own self.
My *ego* is the *ego* of an unique being,
The *homo sapientissimus*,
Of which I am the sole representative.
I have no superfluity of ideas,
And those I have I make go further
Than any other man.
Some critics affirm that I am reaching
Second childhood;
While others declare that I have never left
The first,
Not having yet been weaned—
From contractors' brains;
But I can safely aver that my specifications
Refute their calumnies—
By their senility.
I can specify to order.
I can specify by the metre
In any metre.
I can specify in my sleep
Things that others never dreamt of,
Things they'd like to take a sight at,
So they sometimes tell me.
I am hated by all the gasworks;
But this is jealousy.
Does not my gas command a higher price than theirs?
My specification is unique,
For I can specify
The most inevitable fine
And the most uncertain bonus,
And make no extra charge.
My specification
Turns the contractors' hair grey.
My specification
Says more and means less than any other
At the price.
My specification
Is a certain cure—
For insomnia.
My last specification
Has kept a family for three years
In curl papers.
My specifications
Lick creation,
And I lick—
A corporation's boots.

Vibration and Conductivity.—Signor Murani, in *L'Elettricista*, describes experiments on the influences of vibration on the resistance of wires. To avoid the heating due to friction, the vibrations in a series of metallic wires were induced by an electromagnetic tuning-fork, wires of hardened iron, platinum, hard steel, hard copper, German silver, and manganin being tested, and in no case was any variation in the electric resistance detected by the most delicate methods. It is consequently concluded that the resistance of metallic wires is not altered by vibrations, all results to the contrary obtained by other observers notwithstanding.

TO CORRESPONDENTS.

All Rights Reserved. Secretaries and Managers of Companies are invited to furnish Notice of Meetings, Issue of New Shares, Installations, Contracts, and any information connected with Electrical Engineering which may be interesting to our readers. Inventors are informed that any account of their inventions submitted to us will receive our best consideration.

All communications intended for the Editor should be addressed C. H. W. Biggs, *139-140, Salisbury Court, Fleet Street, London, E.C. Anonymous communications will not be noticed.*

TO ADVERTISERS.

Advertisements should be addressed to the Publisher, 139-140, Salisbury Court, Fleet Street, E.C., and should reach him not later than noon of Thursday. **Special Terms** *for a series can be arranged on application.*

"SITUATIONS VACANT" and "WANT PLACES" Advertisements will be charged at THREE WORDS for ONE PENNY with a MINIMUM charge of SIXPENCE.

TO SUBSCRIBERS.

"The Electrical Engineer" *can be had by Order, from any Newsagent in Town or Country, and at the various Railway Stations; or it can, if preferred, be supplied direct from the Office on the following terms:*

	3 months.	6 months.	12 months.
United Kingdom	3s. 3d.	6s. 6d.	13s. 0d.
Other Places	4s. 11d.	9s. 9d.	19s. 6d.

(Post Free, Payable in Advance.)

Cheques, Post Office and Postal Orders for Subscription and Advertisements should be made payable to C. H. W. Biggs, *139-140, Salisbury Court, Fleet Street, London, and be crossed "Union Bank."*

BOUND VOLUMES.

Vol. XV. of new series of "The Electrical Engineer" can be had bound in blue cloth, gilt lettered, price 8s. 6d. Subscribers can have their own copies bound for 2s. 6d., or covers for binding can be obtained, price 2s.

PAPER PROFITS.

The late Lord Beaconsfield once classed statistics generally into three divisions, and his language in so doing was so impressive that doubtless all our readers will remember the characteristic headings. We feel much disposed to classify similarly the financial statements in the prospectus of the Town and Village Electric Light and Power Company, which has this week been so largely advertised. The statements in this prospectus are, we should say, generally correct, but the omission of other facts tends to put a wrong construction upon them. Thus, we do not doubt but that the eminent electrical authority quoted believes that the Parfitt system is useful for street-lighting with incandescent lamps, but we very much question if ever he would advocate its adoption for private lighting. A series system, as he states, has cheapened street-lighting for arc lamps, but the so-called grandmotherly care of the Board of Trade quite properly forbids the use of high tension on the lamps in consumers' premises. Hence we must conclude that the advantages claimed for the Parfitt system would be confined to street-lighting only. No private consumer could be connected to the series mains. Leaving, now, the technical side, we come to the following statement, that "although the Kingswood installation is for public lighting only, and bears the double expense of night duty and superintendence of plant by day without any income from private lighting, and at a contract price of less than 2½d. per Board of Trade unit (a much lower price than any public lighting undertaken elsewhere), the accounts for the two years ending April 26, 1895, show a gross profit of over 33 per cent. on the receipts. This profit is exclusive of any charge for depreciation, repairs, and renewals, or establishment expenses, items which, although heavy in proportion to the income of the partially-developed installation, will but slightly increase when the private lighting and consequent full development is completed; so that the percentage of such charges will then be very much reduced."

This is, we expect, a most truthful account of the financial state of the Kingswood installation, but the public would hardly gather from it that the gross profit of 33 per cent. is not enough to cover the charges for depreciation, repairs, renewals, and establishment expenses. The total of these charges in small stations is usually over 1¼d. per unit, which in the present case would result in a net loss of 20 per cent. The other conclusion from the report of the auditor, which is not corrected by any statement from Dr. Thompson, is that the gross profits, although showing 33 per cent., would be increased by the addition of private lighting. On the other hand, the facts of the case are, that to undertake private lighting, another system of mains must be provided at additional cost. The installation would then stand on the same footing as any other electric supply station, with the addition on the street-lighting mains on the Parfitt system. The street-lighting, however, could be just as easily supplied from the private supply mains, so that the Parfitt scheme becomes a useless additional expense. We do not consider it worth while to discuss here the doubtful question of the claimed

Digitized by Google

advantages for this system over other series methods of supply, because in the very best attempt the engine power required and the cost of generation are not appreciably lower than with parallel systems. What we do condemn is the practice of publishing gross profits and then omitting to give *contra* items, which not only would swamp the paper balance, but would convert it into a dead loss. We would call the attention of our readers again to the fact that street-lighting in England is practically carried out at a loss by all supply companies. An expert reporting on the lighting of Canterbury by electricity even goes so far as to reckon the cost of coal only when considering the amount to be charged for public lights. In this case he put that cost down at 1·35d. per unit. We do not consider this statement a fair one to put before untechnical councilmen, but it is not likely to cause such a waste of money as the statement in the above-mentioned prospectus. It will also be noted that the prospectus was issued and the dates of application so fixed that the technical Press could not effectively exert its right of criticism in the interests of the public.

CORRESPONDENCE.

"One man's word is no man's word,
Justice needs that both be heard."

THE NEW "RAYS."

SIR,—Will you kindly allow me to contribute a few remarks, through the medium of your columns, on that which forms the subject of Mr. Sydney F. Walker's letter in your last issue? I am, like many others I believe, searching for the true connection between the various manifestations of energy in the form of sound, heat, light, electricity, and magnetism. I have read Mr. Walker's letter with a great deal of interest, but some of the views put forward by that gentleman seem to require further elucidation; for instead of providing a more intimate connection between the phenomena of electricity and magnetism, there appears to be a wider gulf than ever between them. Why should they be placed so far apart in the scale of wave-lengths; and for what reason is electro-magnetism assigned a shorter wave-length even than the ultra-violet rays? It seems to lead to this reasoning: Can a current flowing through a solenoid magnetise its iron core—that is to say, instantly produce in it waves of the highest rate of vibration (leaving out the question of hysteresis) without the iron core going through the intermediate stages of sound, heat, and light? There must surely be a form of inertia wherever molecular motion is concerned, which even the hypothetical all-pervading ether being closed in by the said molecules cannot respond to instantaneously. And, again, the theory respecting the changes of wave-lengths which take place in a conductor as the current is increased does not seem to bear close investigation. Assuming for the moment the conclusions arrived at by Mr. Walker to be correct—*i.e.*, the electro-magnetic wave as having the shortest, and the electric wave the longest, periodicity: if we now consider the case of an electric current flowing along a conductor (or, as Mr. Walker puts it, a series of electric waves of a certain rate of vibration and the current is increased, being still confined to the same area), what is the result? The wave periods become condensed or shorter, passing through the stages of invisible heat, visible red, and at length to ultra-violet light. Now to logically carry out this reasoning a little further, increase the current. Should we not then obtain "pure magnetism" (if I may be allowed to use such a term), which I presume would be invisible? But if an electric current can be explained by the assumption of waves, why do these waves take the path of the conductor instead of the majority of them diverging into space, for it would naturally seem that the ether alone should offer less resistance to waves than the molecules of the conductor surrounded by ether.

One more point which to me seems obscure. Does a different rate of transmission affect the nature of the waves? Are not different wave-lengths and rates of transmission synonymous? Or can there be two or more rates of transmission for the same length of wave?

Tenterden, February 3, 1896. ALFRED H. AVERY.

USEFUL ELECTRIC LAMPS.

SIR,—I have read with but little patience a letter signed by one that chooses the *nom-de-plume* "Fair Play," and it is a palpable fact that his treatment of the matter renders this a misnomer. Anyone conversant with the subject knows that the opposite of fair play is amplified by your correspondent, who inveighs against English manufacturers, and further makes obviously personal reflections under the guise of a *nom-de-plume*. I cannot retaliate in kind, since it is derogatory to bandy words with one, who living in England, openly avows his predilection for foreign goods.

I may draw your attention to the fact that the article and advertisement referred to is based upon the report of the German commission, and that this report does not include a single exception in favour of any one of the German manufacturers; nor, to go further, not a single special make has been set down as a really good lamp. "Fair Play" desires to inform us that he knows a German firm turning out 15,000 lamps per day, and wishes us to infer therefrom that these lamps are actually good ones. I may, in the face of this statement, either take it *cum grano* or draw the inference that the special commission had none of these before them to test. I still hold the opinion that English-made lamps are superior in every point of efficiency to any imported from abroad.

My reason in replying to "Fair Play's" letter is to protest against the perversion of important trade matters, by casting unfounded doubts upon the fairness of the tests upon which the advertisements and articles referred to were based. Most of your readers are aware of the special commission appointed, consisting of central-station and other engineers, and they have condemned broadly the lamps of German manufacture—that is to say, condemning the goods made in their own country in unmistakable terms.

"Fair Play" evidently tries to confuse your readers by omitting any mention of the tribunal referred to, but convicts what he calls unfair tests without reason or logic. His vaunted output of 15,000 good lamps per day should surely be noticed by the commission instead of being obscurely advertised here under an obviously false pretence.—Yours, etc., FREDK. WALKER.

February 4, 1896.

SOUND CASTINGS FOR ELECTRICAL WORK.

SIR,—Referring to Mr. W. J. May's paper on "Sound Castings for Electrical Work," published in your issue of January 24, it would be interesting to know exactly what this "ferro-sodium" is and also where it may be procured. It seems impossible to get it from any of the chemical manufacturers of Glasgow. Perhaps Mr. May will kindly give this information.—Yours, etc., READER.

BARRACK LIGHTING.

SIR,—Would you kindly inform me, through the medium of your journal, whether any of the Government barracks are now lighted with electric light, using their own plant or taking a supply from a public supply station? Thanking you in anticipation—Yours, etc., A. HANDLEY.

[We know of no scheme for barrack lighting actually in use, but have heard of one or two proposed schemes. Perhaps our readers can give the information Mr. Handley requires.—ED. *E. E.*]

THE ARC LIGHT.*

BY PROF. SILVANUS P. THOMPSON, D.SC., F.R.S.

LECTURE III.

(Concluded from page 132.)

SOME RECENT LAMPS.

Of other feeding lamps with tilting mechanism there are several in existence. I examined a very nice one indeed some few months ago, the invention of M. Caneval, of Rouen—a shunt lamp with an escapement designed to work independently of the tilting of the mechanism.

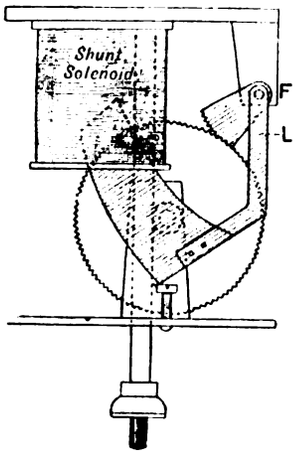

FIG. 30.

There are here two lamps of very simple construction, the invention of Mr. Akester, of London. Both are clutch lamps, and the clutch in this case works on the holder of the lower carbon rod, instead of the upper, while the clutch itself is peculiar. It consists of a little box with some small shot in it. When the small shot is compressed between the top and bottom it grips the rod, and will not let it go. When the pressure is released the shot will roll round, and the rod will slip through easily. There is no end to these mechanical devices for clamping and unclamping automatically by the operation of that which governs the lamp—viz., the electric magnetic mechanism.

Two or three other forms containing improvements in details remain to be mentioned. First, there is here a deservedly popular French lamp, the Briane. This is like the English lamps, but having only one wheel. That wheel has a kind of tooth or milling on the edge, and is governed by a small toothed

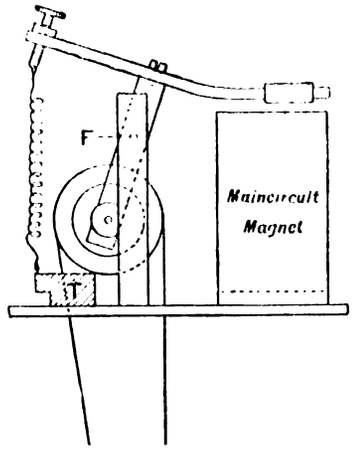

FIG. 31.

sector. That sector (Fig. 30) is fixed to a long crooked lever, having on its end a piece of iron, which can be sucked up into a shunt coil. The play of the lever is limited by a set-screw at the bottom. If the current round the shunt solenoid is strong enough, it will suck up this piece of iron and turn the wheel round a little. If the current is weak it will descend, and the wheel will turn the other way. Whenever the current through the shunt solenoid becomes very strong, the rise of this piece will carry the toothed sector out of contact, and the wheel will be free to turn. But on the descent of the carbon the current in the shunt coil will at once become weaker; whereupon the lever arm comes down again, and the wheel is once more caught. Naturally there will be wear and tear on these teeth; but the lamp seems to work very satisfactorily, both for continuous and alternating currents.

* Cantor lectures delivered before the Society of Arts.

The next picture (Fig. 31) relates to a lamp not worked by a shunt solenoid. It is called the Hard lamp. We find here, again, a single wheel on a tilting frame, the position of which is in this case governed by a main circuit magnet pulling at an armature and opposed by a spring. The wheel is allowed to turn, or is held against a small projecting piece at T. If the current in the main circuit is too strong, it is held fixed; if the arc burns away and the current gets weaker, the armature rises, the wheel is released, and feeding can occur.

THE "THOMSON 1893" LAMP."

In Fig. 32 is shown an American lamp. It is known as the "Thomson 1893" lamp, being the invention of Prof. Elihu Thomson, who has designed many successive forms since 1874.

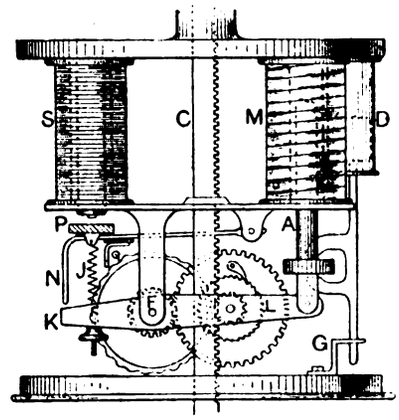

FIG. 32.

In this case a form has been arrived at which has some interesting features. M is a double solenoid, which carries the main current. The yoke, A, operates the lever, L, being, however, controlled by the dashpot, D. The lever, L, forms one side of a frame, pivoted at F, containing the wheelwork seen in the figure. The carbon-rod, C, gears with the first member of a train of wheel. The last member of the train will be seen to be a wheel with a wavy outline (the waves are much smaller and much more numerous than shown in the figure). The wavy rim is made of siiver, and against it there falls, when the lamp is working, an insulated detent, also made of silver. This detent is mounted on a lever, to which is also attached an iron strip, P, which forms the armature of the shunt coil, S. The shunt coil is somewhat sluggish in action, as it has its cores surrounded by a copper tube. The fine wire wound over this has a resistance of more than 400 ohms. The connection of the shunt is made through the silver rim and detent, so that when the detent is not in contact the shunt circuit is broken. The action of the lamp is as follows: When no current is passing, the lever, L, is down, and K being up supports N, so that the wheelwork is free and the carbons in contact. The current being turned on lifts L, and with it the carbon-rod, C, striking the arc, and at the same time allowing the detent to fall, thus closing the shunt circuit. When the arc burns long and S is strong enough, it raises the detent and the lamp feeds one tooth or wave of the silver rim, the current of S being momentarily broken. The sluggishness of S makes the action deliberate and allows the feeding to occur at variations of half a volt. Silver is an excellent metal for a contact such as occurs in this lamp, being better than platinum for the purpose. There is no pumping with this mechanism. A number of improvements in carbon-holders, dust-catchers, globe-shifters, etc., accompany the lamp. For series work a cut-out is provided, which is merely a high-resistance magnet as a shunt to the detent contact, and made still more sluggish than S, so that ordinary feeding actions do not bring it into operation, but the opening of the contact without feeding will give it time to act and close a shunt to the lamp. These lamps are also made to focus, and a modified type is employed with alternating currents.

The feature of the shunt acting as an electric bell vibrating arrangement was used some years ago in a lamp introduced by Gramme, which is but little known. The striking of the arc was accomplished by an electromagnet at the top of the lamp, and the feed occurred by the release of the last member of a train of clockwork by a lever which made a vibrating contact in the shunt-coil circuit. The lamp further resembled the new Thomson lamp in having the series and shunt coils acting independently, the former only to strike, and the latter only to feed.

THE WAX-WHEEL LAMP.

The next lamp which I exhibit is an entire novelty in the English market, though already in extensive use in America. In it all clutches, escapements, springs, and dashpots are eliminated, the feeding being accomplished by the heating effect in a shunt. To a rack on the upper carbon-rod is geared a spindle carrying between two ebonite cheeks a ring made of a white composition of wax. Into the edge of this ring is embedded

Digitized by Google

the head of a fixed pin, which therefore prevents the wax wheel from turning. Upon the upper part of the pin is wound a coil of German-silver wire, having a resistance of about 150 ohms, which is included along with an auxiliary resistance of some 800 more ohms in a shunt circuit. The current which flows through this shunt circuit, though small, is sufficient to warm the pin and cause it to soften the wax in its neighbourhood, thus permitting the wax wheel to turn round very slowly—in fact, about one revolution in two or three hours, but very uniformly. The melted wax solidifies at once after having passed the pin, so that the surface of the wax wheel is left even for the next revolution. The feeding is therefore continuous and very gradual. Should the arc grow long more current flows through the shunt, making the pin hotter and causing the feed to work quicker. The rate of feeding is found to be approximately proportional to the square of the voltage applied to the shunt. This lamp, the invention of Mr. S. E. Nutting, can be used with either alternating or continuous currents. The arc is struck from below by an electromagnet in the main circuit, placed at the bottom. In the latest pattern of this lamp there is an automatic rheostat to vary the resistance of the shunt circuit according to the temperature of the surrounding air; and an ingenious cut-out has been added for lamps designed to run in series.

Lamps for Optical Lanterns.

Since the distribution of electric current from lighting stations became general, much attention has been given to the production of small projector lamps suitable for use in the optical lantern. These are now fast replacing the limelight, and every month sees the introduction of some new forms. The principle of making the ends of the carbon abut against a solid projection, as shown in Fig. 33, is an old one, but it has been revived by Brockie, Scharnweber, and others in lamps intended for use in optical lanterns. The form of abutment usually preferred is that of three obliquely projecting claws or screws, which grip the coned surface of the carbon. For the negative carbon, a steel abutment serves excellently. For the positive carbon abutments are less satisfactory, as they are comparatively liable to be burned away by the arc.

There are on the table, thanks to the kindness of several exhibitors, some of these modern small projector lamps suitable for lantern work. First, I ought to mention the one that has done good service during my lectures—Mr. Davenport's own, of which there are two or three varieties here. That which I have been using in the lantern has an abutment pole below, with a spring to press the lower carbon against the abutting screws. There is a hand-feed behind to move the upper carbon; and there are little details of arrangement, as shown in Fig. 34, for centreing and raising the luminous point.

Fig. 33.

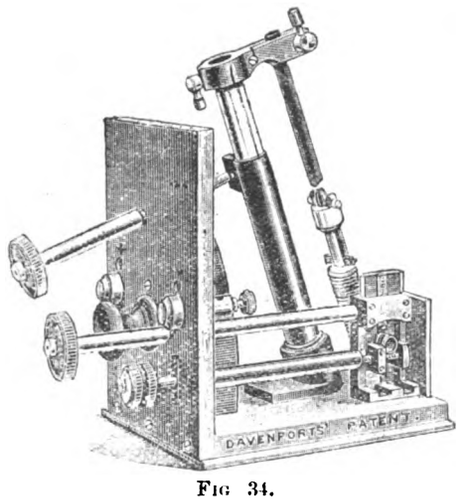

Fig. 34.

Then there are three lamps here made according to Major Holden's patent, kindly lent me by Messrs. Newton and Co., of Temple Bar. In these lamps abutment poles are used, either on the positive or negative carbons, or on both with sundry arrangements of mechanical value for changing the carbons and renewing them. Here, in the first example, are some curious contrivances to enable one to unclamp either carbon and put in a new one, as you put a new candle in a carriage lamp. In this case one has a fine hand adjustment on the lower carbon, and a coarse adjustment on the upper.

Here, again, is a somewhat similar type with hand adjustment above and below, if required. Having two sets of abutment poles, positive and negative, the carbons ought to approach at their proper rates, so that a very small amount of adjustment by hand ought to suffice. The third lamp (Fig. 35), which is of a squat pattern, is also Major Holden's. It has a device for centreing or raising and lowering the thing as a whole, and also for moving the lower carbon so as to lengthen out the arc or shorten it as desired.

Again, here is a little lamp devised by Mr. Borland, of Leeds. It has all the elements of an arc lamp in miniature—a coil to pull up a plunger and strike the arc, and a shunt coil to move another plunger to make the carbons approach one another. With carbons long enough to last four hours this lamp only weighs 3lb. I have found it to work exceedingly well on a continuous-current supply with an inverted arc, using as the lower pencil a soft-cored carbon. The upper carbon, of smaller diameter and uncored, should be set slightly in front of the lower.

A very simple hand lamp, with screw feed, by Mr. A. J. Beaumont, of York, has lately claimed some notice; but I have not had any experience with it.

Mr. Brockie has designed a very perfect small projector lamp with a vibrating clutch feed, in which, also, abutment stops are provided for the negative carbon; but it belongs in reality to the class of lamps with complex mechanism, and, therefore, can scarcely be classed with the simple lamps just mentioned.

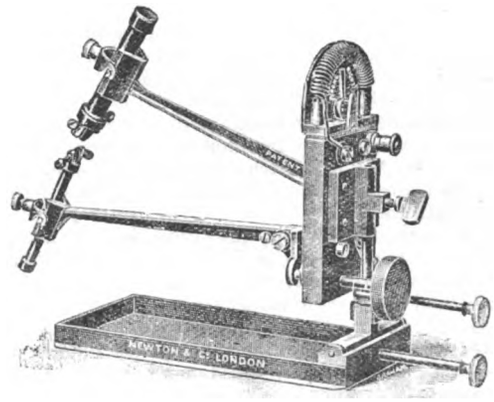

Fig. 35.

One thing has not yet been attained by the inventors of any of the automatic lamps—namely, the production of a lamp that, without any adjustment whatever, shall be capable of being connected up straight to the 100-volt mains of any lighting system, whether the supply be of the continuous or the alternate current sort. The fact is, the universal lamp, which will go anywhere with any sort of supply, has not yet been invented. Perhaps it never will come exactly in that form.

Lamps for 100-Volt Circuits.

There is another direction in which progress has been taking place during the past few years—viz., in the perfection of lamps for the special purpose of running two in series on the ordinary 100-volt mains with continuous current. It is a curious fact that lamps which will work excellently when there are a lot of them in series supplied with a continuous current of fixed value are often difficult to coax into good working when put two in series across 100-volt mains. Some lamps will not work at all. The inventor, however, has turned his attention to the question, and it is now often one of his most important claims that his lamp will work well under these conditions.

There is a somewhat similar problem how to make three lamps work in series when you have an alternating-current supply at 100 volts. They only want 30 volts each, and therefore there ought to be room for three in series across 100-volt mains. The successful solving of that problem surely must depend on some very simple thing. Now that we have methods of testing the nicety of feed, and of adjusting the volts at which the feed will occur, clearly the time ought not to be very distant when one can say that the problem of making lamps to work satisfactorily, two or three in series on 100-volt mains, shall have been really finally solved. Mr. Brockie has remarked to me that none of the old lamps which have glycerine dashpots to prevent the top carbon moving downwards quickly would ever perform this function, for if you would have two lamps to work satisfactorily, and not to go see-sawing one against the other, the one burning dull when the other is bright, they must be capable of dropping their carbons down into contact at the same instant, so that one shall not get down before the other, and strike its arc before the other is ready. They may move up slowly, but they must move down quickly. That is apparently one condition—possibly not the only condition—for the successful working of lamps in series.

Then I think I may conclude here, though time is all too brief for this review of progress since 1889, by saying that there are distinct lines of progress which have been traced in these six years, and that those lines of progress, although they may not yet have brought us everything we desire, nevertheless have witnessed the development of arc lighting into a condition where success has for almost every conceivable purpose been attained. It now remains only to perfect refinements for special purposes, such as those to which I have just alluded.

THE STANDARDS OF LIGHT.*

BY W. J. DIBDIN, F.I.C., F.C.S., ETC.

On December 21, 1888, I had the honour of reading before the Society of Arts a paper on the subject of the standards of light, in which paper I discussed the position of the question as it then stood, summing up briefly the results of the various enquiries conducted from time to time by authorities in this country and on the Continent. The position in which the question had then arrived may be shortly put thus: The authorities of the Board of Trade—the controlling authorities for gas-testing purposes in London—the gas interest generally, as represented by the Gas Institute and the British Association, had all joined in one condemnation of the existing candle, and in demanding an alteration; and, with one exception, that such alteration should consist in the adoption of Mr. Harcourt's pentane air gas-flame.

After careful consideration of these facts, an impartial observer would probably have drawn the conclusion that the time was then ripe for a change, and that legislation would follow without delay. Unfortunately, other counsels prevailed, and we have now arrived at a period seven years later, without the attainment of the alteration so earnestly desired and looked forward to by all those who have made the subject one of special study, and who daily experience the discomfort of having their best endeavours marred by the imperfect nature of the standard employed, as by Act of Parliament they are compelled to use the long since discredited candle instead of one of the known reliable substitutes.

In view of the uncertainty prevailing in the minds of the parliamentary experts of the Board of Trade rather than in that of their scientific advisers, a further series of enquiries was instituted by a committee appointed by that Board on December 23, 1891. The committee was composed of representatives of the two controlling authorities for gas testing in London—viz., the City and the London County Council; the three large gas companies—viz, the Gaslight and Coke, the South Metropolitan, and the Commercial Gas Companies; the gas referees; and two independent representatives of the Board of Trade. In connection with the apppointment of this committee, it is to be noted that it was not until the South Metropolitan Gas Company came forward with an offer to meet the expenses of the committee that it was constituted, as neither the Board of Trade nor the controlling authorities had funds at their disposal for that purpose. Probably this action on the part of a commercial company forms a stronger argument in favour of the long-desired alteration than can be put into words.

After three years of most patient work, during which all the points were carefully and exhaustively reviewed, that committee issued its report, and the question has consequently taken one more step forward, although, as a matter of fact, the scientific result is, to all intents and purposes, in much the same position—viz., the candles are (if possible) still more hopelessly condemned—and one of the proposed more reliable substitutes recommended for adoption in their place. Mr. Harcourt's pentane standard has again been vindicated as a reliable and exact standard; and for practical use in gas-testing the pentane-Argand, proposed by myself in 1886, has been chosen as a suitable substitute for candles in daily work.

It is to be hoped that the unanimous report of a committee expressly selected so as to include representatives of all the various interests concerned will result in speedy legislation, and thus at last put an end to a controversy which has been one of the vexed questions of the day for over 20 years. In the meantime, it will be desirable that the essential features of this last official report should be fully discussed, and, with that view, I venture to submit the following summarised account of the work of the committee as given in the report. The various points may be considered in the following order:

1. Unsatisfactory standard furnished by the flame of a sperm candle, by reason of the amount of light which it affords varying over a wide range, under conditions as to the manufacture of the candle, as to its mode of use, and as to the adventitious circumstances attending its use, which, as a whole, it is not possible to regulate and define.

2. The advisability of continuing to express, as heretofore, in official documents and reports, the quantity of light yielded by coal-gas burned under specified conditions, in terms of candle-light, the actual comparison, however, being made between the gaslight and some well-defined and constant light ascertained to be equal in quantity to, or a definite multiple of, the average light given by the standard sperm candle.

3. The conclusion that, in the present state of experience and knowledge, the source of light to be used as a standard by gas-testers generally must be produced by the process of combustion, and be in the nature of a flame.

4. That the one-candle light flame proposed by Mr. A. Vernon Harcourt does constitute a very exact standard, capable of being reproduced at any time without variation of illuminative value, and that this flame is a true representative of the average light furnished by the sperm candle flame constituting the present standard.

5. Inasmuch, however, as there is a practical advantage in comparing directly the light of such a coal-gas flame as is usually tested (being, that is, of about a 16-candle light value), with a light approximating somewhat in value thereto, the committee submitted to careful examination the flame of the 10-candle light pentane-Argand proposed by the author as a standard in 1886. This flame is produced by burning a mixture of air and pentane vapour from a suitable Argand burner provided with an opaque screen, by which the light from the upper portion of the flame is cut off. The screen being set at a definite height, the luminosity of this portion of the flame remains constant even under considerable variations owing to a compensating action affecting the lower or exposed portion of the flame.

6. The amount of light emitted by the lower portion of the flame is substantially equal to 10 times the average light of a standard sperm candle flame, or to 10 times the light of Mr. Harcourt's one-candle light pentane air-gas flame.

7. That any number of the Dibdin Argand burners may be produced, and may be depended upon to furnish a flame giving, when duly screened at the top, 10 times the average amount of light given by a sperm candle.

8. Then follows the recommendation that the pentane-air flame furnished by this pentane-Argand burner be accepted as giving the light of 10 standard candles, and that it be authorised and prescribed for official use in testing the illuminating power of the gas supplied by the London gas companies.

9. With a view to making some provision for future possible improvements and requirements, the committee further recommend that the gas referees be authorised, should they at any time see fit, to approve and certify for gas-testing any other flame based upon the 10-candle standard defined above which they may consider suitable for the purpose, whether produced in a like or unlike way, and having the same or a different multiple value; such other flame, however, not to be used for gas-testing unless approved by the Board of Trade, and unless the gas companies give their consent to its adoption as a standard.

10. The committee then proceeded to recommend that the illuminating power of coal-gas shall continue to be recorded, as heretofore, in terms of the light given by a specified number of cubic feet—to wit, five cubic feet—burnt per hour from the standard London Argand burner, but that the requirement that the gas shall actually be consumed at that rate be rescinded, so as to allow the gas referees to sanction a mode of testing in which the gas shall be burned at whatever rate is found requisite, in order that it may give a light equal to that of the prescribed number of candles, and in which the illuminative value of the gas shall be calculated as being inversely as the rate at which such gas had been burned during the testing, so as to give this amount of light.

The chief error in the amount of light emitted by a candle is due to variations in the character of the wick employed. Exhaustive experiments have shown that the number and size of the threads in the wick, the closeness of the plaiting of the strands, the pull on each strand during plaiting, the previous cleaning of the cotton used, the treatment of the wick by the manufacturer, and the extent to which the wick is stretched when set in the candle-mould by the workman, are all factors of considerable importance affecting the light which a candle gives. Various other conditions also affect the result, such as the length of time it has been burning, whether the "cup" of the candle is dry or contains melted sperm, the roughness or smoothness of the wick, the curvature of the wick, etc. Added to these difficulties, we have the impossibility of making candles which will burn 120 grains an hour. The gas referees' instructions allow the use of a candle burning within 5 per cent. of the prescribed amount, but even this does not overcome the trouble, as candles very frequently burn outside these limits, departures of even 10 to 20 per cent. being by no means unknown.

In Germany sperm candles have been abandoned for paraffin candles, made under the supervision of the authorities, and specially marked; but the same troubles are experienced as with the sperm candles.

The committee, therefore, unhesitatingly recommended the abolition of the candle as a standard of light, and the introduction of some more reliable unit.

The decision of the committee respecting the continuation of the practice of stating the quantity of light in terms of the candle will doubtless recommend itself to all persons interested in the question. The unit thus expressed is one which is well understood generally, and whilst being in itself convenient, represents a quantity of light which is practically the smallest used in daily life. It is only exceptional radiants, such as the arc light, concentrated by a lens, that emit larger multiples of this unit than a few hundred times its value, and no inconvenience can be experienced in such cases; whilst the introduction of a new term, such as the "carcel," would lead to unnecessary confusion.

The expression of opinion that the source of light to be used as a standard must be produced by the process of combustion, and be in the nature of a flame, is well advised in view of the experience of the past. As I pointed out in my previous paper in 1888, numerous investigations had been made as to the possibility of producing a constant light by a process of incandescence of solid bodies, notably platinum; but the unreliability of such methods was well illustrated by the researches of the British Association Committee, aided by the work of this society, through its secretary, and since that time no progress seems to have been made in this direction. The suggestion to obtain a constant light by means of the incandescent electric lamp has completely broken down, in consequence of the more or less rapid depreciation of the initial intensity, owing to the gradual discolouration of the interior surface of the glass globe.

The following series of special experiments on this point will serve to show the difficulty with which such a standard would have to contend. The tests were made when the current was practically constant:

Number of hours the lamp had been alight.	Illuminating power.
0	14·8
96	14·0
188	13·0
307	11·5
357	11·8
453	10·8
520	11·5
612	10·5
709	10·3
761	10·5

The loss of 5·4 per cent. in the first 100 hours might not be considered an insuperable difficulty, as a lamp could be renewed at more frequent intervals. Another practical difficulty, however, is the variation in voltage of the current, a loss of only 3 per cent. having been found to affect the quantity of light by as much as 27 per cent. From these facts it will be seen that the committee had good reasons for their decision.

The conclusion that Mr. A. Vernon Harcourt's pentane-air gas flame constitutes a very exact standard is only one more piece of evidence in favour of the admirable work of that gentleman. Although the particular form in which the pentane and air are to be employed, if the decision of the committee takes legal effect, has been varied by the introduction of the pentane-Argand burner, the thanks of the community are due to Mr. Harcourt for first calling attention to the standard combustible material thus adopted. Without his preliminary investigations in this direction, it is probable that the question would have still been further from solution than it is at present. It is, indeed, only due to that gentleman to place on record once more the altogether admirable work with which his name is associated.

It is to be noted that the work of the committee resulted in the discovery of a point in connection with the one-candle pentane-air gas flame which had been overlooked in certain previous investigations. This was that, when the flame was set by an observer who viewed the whole of the luminous portion the tip of the flame was set too high as compared with the settings made when the body of the flame was obscured by a screen. A number of experiments made to determine the error thus introduced gave a mean difference of 2·59 per cent. On applying this correction to those average results obtained by means of the pentane flame, when it was set without the use of a screen, the committee found the following values of the pentane-air gas flame as obtained at various periods by different observers who had compared this proposed standard with candles:

Observer.	Value in standard candles.	Date.
Mr. Vernon Harcourt	0·994	1879
Messrs. F. Livesey and W. Brown	0 990	1879
Mr. Harold B. Dixon	0 998	1881
Mr. Dibdin	0·998	1887
,, or, including all experiments	1 016	1887
British Association Committee	1 006	1888
Mr. Greville Williams (a)	1 008	1891
Mr. Greville Williams (b)	1 050	1891
Prof. Harold B. Dixon	0·998	1891 2

The mean value of all experiments made between 1878 and 1892 with the pentane unit against standard candles when thus corrected, ascribes a value of 1 007 to the pentane flame. If one abnormally high result be omitted, the value becomes 1·001.

Satisfactory as this result was, it was nevertheless felt that in order to reduce as far as possible any errors which atmospheric influences might introduce, it would be best to adopt for the daily testing of gas a standard burner giving a light nearly approaching that of the flame to be tested, which can be easily worked, and in which slight errors in manipulation shall not give rise to serious errors in the results. The 10-candle petane-Argand seemed to satisfy these conditions, and the committee undertook the requisite experiments to determine the point. The burner used was supplied by Messrs. Sugg and Co., and on standardising it under the prescribed conditions by the one-candle pentane-air gas unit, it was found to give a value of 10·004 candles. The preliminary experiments to ascertain if very extreme variations in the height of the flame affected the amount of light given out showed that, with the extreme limits possible, which could never be approached with the most careless manipulation, the deviation from the normal value would only raise the standard by 1·0 per cent. or decrease it by 6·2 per cent., this latter result being obtained when the flame was tailing above the top of the chimney! An extended series of observations was made to ascertain within what limits of height of flame the light passing under the screen of the standard burner remained constant. At the same time the effect of replacing the air with coal-gas was tried to see whether any, and, if so, what, difference would be caused thereby. The result showed that both with air and with coal-gas the 10-candle pentane-Argand gave practically uniform results with a flame burning between the limits of 2½in. and 4½in. in height, whilst if by any mischance these very wide extremes should be exceeded, the results obtained are slightly in favour of the gas being tested. In like manner, experiments made to ascertain whether the depth of pentane in the carburetter influenced the light by altering the amount of air space over the surface of the pentane resulted in showing that as long as there is sufficient pentane to cover properly the bottom of the carburetter, the results obtained will not vary, whilst they again established the fact that atmospheric air may be used instead of coal-gas as the carrying medium. Another most important point is that the temperature of the carburetter may vary about 40deg. F.—viz., from 40deg. to 80deg. F.—without influencing the value of the standard. The only alteration found was in one case, when the level of the pentane was too low; but when the carburetter was kept about half full of pentane the results were constant.

Testings were further made to ascertain what change, if any, the 10-candle pentane-Argand might undergo as the atmospheric pressure varies. From these the conclusion was drawn that the value of the standard is not materially affected by such variations of atmospheric pressure as commonly occur.

INSTITUTION OF ELECTRICAL ENGINEERS.

The following is a synopsis of a paper on the construction of a form of Wheatstone's bridge box to be read by Mr. Gustav J Lemmens at a students' meeting on Friday. February 7, 1896 :

Object of present paper. Cost of usual types of boxes, £10 to £50 Below £10 no boxes measure with greater accuracy than ½ per cent., and above £50 they may be considered as standards.

Dimensions of boxes. Peculiarity in proportional coils. Seventeen arm coils and a stretched wire. Overall dimension, $23 \times 9 \times 10\frac{3}{4}$ Nominal range, 0—200 megohms. Accuracy. Drawbacks. General consideration of errors due to (*a*) uncertainty of temperature, (*b*) faulty adjustment (these in the above-mentioned boxes amount combined to ·05 to ·1 per cent.) ; other sources of error, (*c*) imperfect contacts, (*d*) thermo-junctions. Temperature error and its cure. Usual method of ascertaining temperature faulty. Relative temperature of atmosphere, coils, and interior of box. Coils. Choice of material limited to German silver, platinum-silver platinoid, and manganin. Superiority of manganin. Comparison of properties :

	A.	B	C.	D.
Pure annealed copper	1·624	·388	3s. 4d.	—
German silver (Cu4. Ni2. Zn1)	20·9	·044	6·5d.	+15·5
Platinum silver (Pt2. Ag1)	24·36	·031	50s.	—
Platinoid (Cu4. Ni2 Zn1. W.) trace	32·8	·021	4·8d.	—
Manganin (Cu84. Mn12. Ni4)	42·0	·0025	3·5d.	+ 1·5
Iron	—	—	—	- 14·5
Other alloys in common use	—	—	—	+20 to 30

A = Specific resistance legal microhms per cubic centimetre at 0deg. C.
B = Temperature coefficient per cent. per 0deg. C. over ordinary range.
C = Cost of wire for 10-ohm coil of 22-mil wire D.S.C.
D = Thermo E M.F. against pure electrolytic copper in micro volts per 0deg. C

Dr. St. Lindeck on manganin. Temperature coefficient negligible for most purposes. Curve of temperature coefficient exhibited. Treatment and constancy of manganin.

Household oven suitable for annealing. Errors of adjustment in coils. Usual mode of adjustment. Specimen bobbin exhibited Disadvantages

Suggested improvements in methods of winding coils Apparatus for winding coils exhibited Shellac used instead of paraffin for insulating, probably on account of annealing. Reason for anneal ing. Process of adjusting coils. Suggested improvements Accuracy attained in first coil adjusted by this method = 02 per cent., with very little trouble in one-ohm coil. Further accuracy of coils ensured by device due to Prof Ayrton. Errors introduced by imperfection of contact. Usual form of plug : difficulties of construction and unreliability. Special form of mercury-cup proposed. Block must be made of copper, not brass. Device for securing against leakage of mercury.

Sizes of wire. Sizes usually employed Sizes proposed Accuracy of measurement depends on knowledge of temperature. Usual accuracy of coils ·05 to ·1 per cent. Standard of accuracy proposed = 005 per cent., allowing an uncertainty of temperature of 2deg. C. Emissivity of coils taken as ·00706 watt, or 001681 calorie per second, per square inch exposed per degree C. excess temperature. ∴ watts given to coil ÷ watts emitted per degree C. = 2deg. C. This temperature is never reached. List of sizes of wires, carrying capacity of each coil in amperes for given rise, volts at terminals, and time to acquire a rise of 95 per cent. of 2deg. C. exhibited. Specimen curves to latter exhibited. Calculations of carrying capacity and temperature curve.

Final details of box. Special tool for boring mercury-cups. Stretched wire, materials, manganin gilt, platinum-iridium or platinoid. Objection to gilt manganin lies in proximity to mercury. Method of obviating this difficulty. Means adopted for keeping wire accurate while in use.

KINGSTON-UPON-HULL ELECTRIC LIGHTING ACCOUNTS.

The accounts of the Electric Lighting Department for the year ended December 31, 1895, have been issued. The capital expenditure during the year amounted to £6 398. 2s. 4d , and the total expenditure to December 31, 1895, has reached the sum of £45,429. 16s. 1d. We give below the revenue account and general balance-sheet for the past year :

GENERAL BALANCE SHEET.

Liabilities	£	s.	d

LEGAL INTELLIGENCE.

ELECTRIC LAMP CASES.

Frazer v South.

In this case, tried on the 30th ult. in the Westminster County Court before his Honour Judge Lumley Smith Q.C., plaintiff, a dealer in electric appliances, carrying on business at Cecil court, Charing Cross-road, sued the defendant, Mr Harry South, an electrical engineer, of Garrick-street to recover the sum of £11 in respect of two electric lamps supplied to the order of the defendant in October last. The lamps were at first supplied on approbation, but the defendant kept them for six weeks, and after that time several applications were made for payment, but he took no notice, and the action was brought.

Mr. Wm. Adam Frazer was called, and said the goods were supplied to the defendant's manager on approbation As he did not return them within a reasonable time, an invoice was sent in in due course, but he took not the slightest notice of it

The defence was that the goods were never ordered by the defendant, but were simply ordered on approbation at the instance of Mr. Vernon Dowset, manager of the Tivoli Music Hall, on whose behalf defendant was acting.

Mr. Vernon Dowset was called, and said the defendant had the contract for supplying electric light at the Tivoli and at the request of the plaintiff he (witness) authorised him to try two of the lamps in question They were not found to be successful, however, and witness was under the impression that they had been returned.

The **Defendant** said that what he did in the matter was purely at the instigation of Mr. Dowset, and he never in any way made himself personally liable for payment of the plaintiff's claim.

His **Honour** said that if the defendant did not intend to be liable for payment he should have made it clear to the plaintiff. He had failed to do so, however, and judgment would be for the amount of the claim, with costs.

Francis v. Spilsbury.

This case was heard in the same court on the following day. The plaintiffs are electrical engineers carrying on business at Victoria street, Westminster, and they sued the defendants, who are dealers in electrical appliances, to recover the sum of £6 odd, which sum, it was alleged, had been over-paid in respect of a large number of Swan Edison lamps supplied. The plaintiffs' case was that they were engaged in installing the electric light at a London hospital, and for the purpose of carrying out the work they ordered several hundreds of lamps of various kinds from the defendants, who are agents for the Edison and Swan Company. The goods were duly delivered packed in a case, but upon their being unpacked it was found that there was a large number of lamps deficient. The defendants were acquainted of the fact, but in the meantime they pressed for payment of their account, and by an oversight a cheque was sent to them for the full amount. Subsequently several applications were made to them to complete the order, but they declined to recognise the fact that they had sent 75 lamps short, and consequently the plaintiffs had to go and purchase more lamps direct from Messrs Edison and Swan, with the result that so far as the 75 lamps in dispute were concerned they had been paid for twice over.

Mr. O'Brien was called, and said he was the engineer to the plaintiff firm, and had the work in question under his charge. In July last year he ordered several hundred lamps from the defendant firm, but upon their being unpacked it was found that there were 75 short. The defendants refused to make good the mistake, and consequently the plaintiffs had to go to Edisons and purchase more, and inasmuch as the defendants had been paid the full amount of their bill, the plaintiffs had had to pay twice over for the 75 lamps which were deficient.

The **Defendant** was called and said his firm were agents for the Edison and Swan Company, and upon receiving plaintiffs' order it was sent on to that firm to execute. He had made enquiries of Messrs. Edison and Swan, and had been assured by them that the goods were properly packed, and that the right number of lamps were enclosed in the case.

The packer and checker from Messrs Edison and Swan's firm were called, and both swore positively that when the case left their firm's premises it contained the proper number of lamps.

In giving judgment, his **Honour** said the facts of the case according to the evidence were very difficult to deal with, but on the

Digitized by Google

whole he thought that it was quite consistent to assume that the mistake in the packing arose on the premises of Messrs. Edison and Swan. The judgment, therefore, would be for the plaintiffs for the amount claimed, with costs.

COMPANIES' MEETINGS AND REPORTS.

ST. JAMES'S AND PALL MALL ELECTRIC LIGHT COMPANY, LIMITED.

The ordinary general meeting of this Company was held on Tuesday at the Carnaby-street central station, Golden-square. Mr. Eustace A. Balfour presided.

The annual report and statement of accounts were taken as read.

The **Chairman** said that before formally proposing the adoption of the report and accounts there were two or three observations he should like to make, chiefly in reference to the working of the Company since last the directors had the pleasure of meeting the shareholders. He thought they might fairly congratulate themselves on the result of the year's working. The Board proposed a dividend of 7¼ per cent. on the ordinary shares, as against 6½ per cent. last year and 4½ per cent. the year before that. He was glad to say that the hope he expressed last year, that there would be something to divide among the founders' shareholders, had been fulfilled. They proposed a dividend on the founders' shares of £2. 19s. 6d. per share. During the past year the number of lamps connected had been increased by 22 per cent., but what was still more satisfactory was the progress of their business during the present year. Since January 1 they had had applications for no less than 6,000 lamps, and in addition to that they had actually increased their gross revenue during the first four weeks of 1896 by £1,200. The actions instituted against the Company alleging nuisance from the plant at Mason's-yard station had been arranged, but the directors had arrived at the conclusion that it would be necessary to charge the whole of the expenses incurred and the cost of refitting the engines in use at the station to the revenue. That had been delayed as long as possible with a view of determining the best method of overcoming the difficulty and trouble. Unfortunately, no definite conclusion could be come to in time to avoid legal action in the matter, but the directors were fully satisfied that the fault was to be found in the engine itself, and that the engines must not vibrate During the last half-year more than half the engines had been sold at a considerable loss, but being satisfied with the new engines which had been put in, the directors had decided to sell the whole of the old engines, and so refit the whole of the machinery at Mason's-yard station. They expected that this would incur a further loss of about £1,500. At the same time, steps had also been taken at both the Company's stations to stop all possible complaint due to the emission of smoke or dust from the chimneys, and they felt confident of being able in future to carry on their business without causing any annoyance to their neighbours. In November a further issue of £20,000 of debenture stock was made to the shareholders, and was considerably over-subscribed for. The directors did not anticipate, unless unforeseen events occurred, that there would be any necessity for raising further capital during the present year. They expected to have an order from the parish of St. James to light the principal thoroughfares in the district, and they were quite prepared to light it. Last year they were able to announce that the cost of working had been reduced by ¾d. a unit, and great credit was due to the staff for having still further reduced the cost by ¼d. a unit. The directors had made efforts to come to an arrangement with the founders' shareholders, but unfortunately the offer made by the Board, subject, of course, to the approval of the ordinary shareholders, had not been unanimously accepted, and therefore the negotiations fell to the ground The Chairman announced that his brother, Mr. Gerald Balfour, M.P., had ceased to be a director, as, on his appointment as Irish Secretary, he did not feel himself justified in retaining his seat at the Board. In conclusion, he thanked the staff, especially Mr. Walker (general manager and secretary) and Mr. Dobson (chief engineer), for the zeal and ability they had shown in the Company's interests, and formally moved the adoption of the report and accounts.

Mr. Latimer Clark, vice-chairman, seconded the motion.

A **Shareholder** said he had hoped some arrangement would be come to with the holders of founders' shares. Did he understand that those holders were above price?

Mr. Fry said he took a most prominent position in trying to negotiate this matter, but he regretted to say their endeavours came to nothing. The proposal which emanated from the Board he considered most fair and reasonable, and if the Board had gone further in the matter he felt convinced that the ordinary shareholders would not have consented to greater terms. The holders of founders' shares, of course, had their rights, but he thought that in the interests of the Company it was essential that those shares should be done away with. The directors' hands would then be unfettered, and he strongly urged, even if a large price had to be paid, that some arrangement should be come to.

Dr. Ware thought the founders' shares were a millstone round the Company's neck, and he would be glad to see them paid off, of course, not at an exorbitant rate, but he would say even at an extravagant price.

The **Chairman** said he was entirely in sympathy with the desire to come to an arrangement with the founders' shareholders, but there was a point beyond which the shareholders, of course, would not go. In their offer the Board reached the very utmost limit they could possibly advise the shareholders to accept, and that being so they arrived at the end of the matter; but the offer was, of course, still open. The articles of association required that the offer must be accepted by the whole of the holders of founders' shares—there must not even be a minority of one; and as for the suggestion that they should alter the articles of association, that required as much unanimity among the founders' shareholders as the offer did. It was unfortunate, but it was so. In reply to questions, the Chairman said the terms proposed were the allotment of 80 ordinary shares at par for each founder's share. At the time the offer was made it was equivalent to £280 per founder's share, and at the present market value it would have been something like £400.

A **Shareholder** said he thought that was an extremely low offer; he thought they might offer considerably more than that.

The report was adopted.

Mr. Bennett Fitch, M.I.C.E., and Mr. Walter Leaf were re-elected directors; and Messrs. Deloitte, Dever, Griffiths, and Co. were re-elected auditors.

A vote of thanks to the chairman concluded the meeting.

GIANT'S CAUSEWAY AND PORTRUSH ELECTRIC TRAMWAY.

The annual report of the directors of this Company says: Your directors have to report a considerable increase in the receipts during the past year as compared with those of the year 1894. In the passenger traffic there has been an increase in the number of first-class passengers to the extent of 931, and an increase of 4,768 in the number of ordinary passengers, making a total of 99,616 compared with 93,917 in 1894. The receipts have consequently risen from £2,873. 13s. 11d. in 1894 to £3,107. 9s. 5d. in the past year. The goods and mineral traffic rose from 26 to 42 tons, while the corresponding receipts have risen from £12 5s. 1d. to £14. 8s. 7d. during the year; the miscellaneous receipts and those for parcels from £28. 7s. 5d. to £33. 18s. 6d.; so that the total receipts from the revenue account have been £3,156. 1s. 6d. as against £2,914. 6s. 5d. in 1894. On the other hand, there has been a considerable increase on the expenditure side of the account, which shows a total of £2,426. 5s. 2d., as against £2,189. 8s. 3d. in 1894. There is, however, a credit balance on the result of the year's working of £729. 16s. 4d., as against £724 18s. in 1894. The large expenditure on revenue account has been caused by a lawsuit in which the Company were engaged, and which could scarcely have been avoided without appearing to give a tacit consent to the establishment of a public right of way along a portion of the railway part of the line. A defendant was fined by the Bushmills bench of magistrates for a trespass on one portion of the railway, and on the same occasion he was prosecuted for an exactly similar trespass on another portion of the railway, when suddenly the question of a claim to a public right of way, not across, but along the line, was raised by a member of the bench, though the defendant had not put in an appearance, and was not represented, and the case was dismissed. Your directors sought to set this decision aside in the Queen's Bench, but they were defeated on the technical ground that a defendant could not be tried twice for a criminal offence, so that the real merits of the case, so far as they involved the question of a public right of way, were not tried at all, and it affords a remarkable travesty of the administration of justice in Ireland that it took four judges, four Queen's counsel, and two junior counsel, occupied for two days, with any amount of affidavits, to decide whether a trespassing pauper should or should not have been fined 2s. 6d., involving, as it did, a cost of over £260, of which the Company were required to pay £229 3s. 3d. Another large item in the expenditure of the year is that for "compensation"—£159. 1s. The greater of this was an instalment payable to the injured lady referred to in our last two reports, and £50 were paid for the funeral and other expenses connected with the death and removal to England of the unfortunate cyclist who got killed on the line through his own carelessness Your directors thought it better to be liberal in regard to this matter, but they steadily refused to acknowledge any liability in the way of damages, though at first threatened with an action. One more instalment of £100 remains due to be paid out of the income of the ensuing year to the aforesaid lady, and your directors hope that in future items under the heads "law costs" and "compensation" will disappear from their accounts, if they have again the good fortune in these respects which they enjoyed for so many previous years. The item for "maintenance of way and works" appears large—£290. 13s. 11d., as against £225. 6s. 4d. in 1894, and £178. 9s. 11d. in 1893. This has arisen from the necessity of making two new sidings, or passing places, on the line, and lengthening some of the others, so as to meet the rapidly increasing traffic, the number of passengers during the past year having risen to within 400 of 100,000. In spite of all the misfortunes enumerated above, the net balance to credit on the year's working has increased from £724. 18s. 2d. to £729. 16s. 4d., as already stated. Your directors have, therefore, every confidence in the future of the line, though they are still unable to give the shareholders any immediate benefit. One result, however, of the unfortunate accident above referred to has been that the Board of Trade, after an enquiry held in Portrush by Major Cardew, R.E., on their behalf, have required the Company to adopt the overhead system of electric current, instead of that by the present conductor rail, which is only 18in. above the ground. Your directors roughly estimate the cost of this change at £5,000, but the available electrical power

Digitized by Google

will be considerably increased. It is rather an anomalous state of affairs in Ireland that every facility for light railways, either by cheap money or by absolute gifts from the English Exchequer, should be given to those parts of Ireland which do nothing for themselves, and that interest at 4 per cent. should continue to be charged for loans in the North of Ireland, where private enterprise has done so much, and with so little return. It must be borne in mind that your line from Portrush to the Giant's Causeway has not only opened up the whole district, and developed the tourist traffic to that far famed region, but that it affords one of the best and cheapest outlets for the enjoyment and recreation of the working classes of Belfast and the other commercial towns in the North of Ireland. Under all the varying and untoward circumstances of the Company the interest of £400 a year has been regularly paid to the Board of Works, and even £225 of capital paid off to them, out of revenue, and your directors entertain the hope that the Government and the Treasury will advance sufficient additional capital at a lower rate of interest than that heretofore paid to enable the Company to carry out the requirements of the Board of Trade The number of miles run by steam power during the year has increased from 10,487 to 14 829, the cost being 10½d per mile: those run by electrical power have been reduced from 20,643 to 17,323, at a cost of 4d. per mile. The total number of miles run has increased from 31,130 to 32,152, and the cheapness of electricity as a locomotive power is still apparent.

YORKSHIRE HOUSE-TO-HOUSE ELECTRICITY COMPANY.

The ordinary general meeting of this Company was held on Tuesday at Leeds, Mr. Grosvenor Talbot presiding.

In moving the adoption of the report, a copy of which appeared in our last week's issue, the **Chairman** said the profit available for dividend from last year's trading amounted to £6,321, and they brought forward from last year's account £162 making a total of £6,483 to be dealt with. In July last they declared an interim dividend at the rate of 4 per cent. per annum, which took exactly £1,000. The directors now recommended a dividend at the rate of 6 per cent per annum for the half-year just ended, making 5 per cent. for the whole year. That required £1,665. 7s 7d. The directors also recommended that they should carry to the reserve fund for depreciation and other purposes the sum of £3,300, leaving a balance to carry forward of £517. 16s. 4d. The directors felt that this year, as well as a dividend at the rate of 5 per cent. per annum, they had been able to offer considerable advantages to the shareholders in the shape of new shares which had been allotted. All shareholders had as many new shares offered them at par as the number they then held, and as the £5 shares were now selling at £7 to £7. 7s., and those on which £1 had been paid were selling at £2 7s. 6d, they felt that that was equivalent to a very handsome bonus. They also felt that it was very desirable that they should accumulate a considerable reserve fund for depreciation and other purposes. Up to the present time they had no reason to regret a single step that they had taken in the erection of the plant and machinery, but there were possibilities in electrical science which they must always bear in mind, and which possibly might render advisable expensive alterations that they would more willingly entertain if they had in hand a considerable reserve Last year the business had been satisfactory. The total receipts had been £11.431, as compared with £7,457 in the previous year; and their expenses had been £4,617, as against £3,747 in 1894. The net profit was £6,780, as compared with £3,709 in 1894 Thus, the total revenue had increased by 57 per cent, and the expenses had only increased by 25 per cent., leaving a net profit of 82 per cent. more The cost of coal had been only £670 for the year, and had beaten the record per unit of any station in the United Kingdom. Since the report was issued the directors had signed an agreement for the purchase of the Britannia Mills, adjoining their offices, as they felt that the possession of such a property would be of enormous value to them in the future. For some years the property would remain in its present condition, but when it was necessary to make extensions the work could carried on more economically than on a new site, and a very expensive and complicated rearrangement of the system would be avoided. The premises in question were well let, and it would not be necessary to disturb the tenants; and after paying the interest on the purchase money a satisfactory balance would remain to the credit of the property. Proceeding to refer to the popularity of the system of lighting by electricity, Mr. Talbot remarked that there was now a sum of over £8 000,000 invested in electric light companies. When the Leeds company started supplying the current in 1893 there were 35 towns in the provinces using the light, and now there were 89. As to the question of new plant, he observed that the directors had ordered two vertical engines of 500 h.p., each running at 355 revolutions, with direct-coupled alternators. This involved to a certain extent a new departure, as there was no station in England where a plant was in existence similar in every way to what they required in Leeds, and running under such stringent conditions. The directors had, however, obtained such guarantees and assurances as satisfied them that the requirements would be carried out in their entirety; the new engines and alternators would run in parallel with the old plant, also by themselves alone when needed, and the whole plant would be practically noiseless.

Mr. A. G. Lupton seconded the motion, and it was carried, as were formal resolutions for the dividend and re-election of retiring directors, etc.

CONTRACTS FOR ELECTRICAL SUPPLIES

CONTRACTS OPEN.

Parma (Italy).—The municipal authorities of the city of Parma desire tenders by February 25 for the electric lighting of the city from June, 1897, to 1912.

Beziers.—Offers are wanted by February 15 for a concession for an electric tramway, about 8,800 metres (5½ miles) long. Particulars at the Mairie, Beziers, France.

Manuel.—Offers are wanted for the electric lighting of the town of Manuel, in the province of Valencia, Spain, for 15 years. Number of inhabitants, 1,500. Price suggested, 1,500 pesetas, payable monthly.

Belper.—The gas company are considering the setting up of an electric lighting plant, and electrical contractors can obtain information as to it on application to the Managing Director, Gas Company's Offices, Belper.

Teneriffe (Canary Islands).—Tenders are invited for the electric lighting of the town of Santa Cruz, Teneriffe, for a period of 35 years. Particulars can be obtained at the Ministerio de la Gobernacion, Madrid, and tenders must be delivered by February 29.

Brunn (Austria).—The Municipality desire offers for the construction and working of a central station for the supply of electric energy for lighting the town, for power, and, if required, for running a tramway. Tenders must be sent before March 31 to the Bürgermeister, Brünn, Austria, from whom particulars can be obtained.

Harrogate.—Tenders are invited for the various works required in the erection of electricity generating station on the Corporation farm, near Harrogate, for the Corporation. Plans and specifications may be seen and quantities obtained. Tenders are to be submitted by 10 a m. on 10th inst Mr. Samuel Stead, borough surveyor, Municipal Offices, Harrogate.

Brussels.—The Belgian State Railways are offering for tender the work necessary for the alteration of the conductors and wiring for the electric lighting of the Marbehan Station. The contract is part of a rearrangement of the water supply, and particulars are obtainable at the Bureau du Chef du Service, Arlon, Rue de la Station, 26 Tenders must be in by February 20.

Eston.—The Eston Urban District Council invite schemes for lighting the district by electricity. Such schemes to embrace (*a*) plan and estimated cost, (*b*) annual working cost and maintenance. Plan of the district may be seen and particulars obtained of Mr. T. W. Stainthorpe, A.M.I.C.E., district surveyor, Grangetown, Yorkshire, to whom the plans, etc., must be sent by May 1.

Rochdale.—The Paving Committee invite tenders for electric lighting plant required at the sewage works, Roch Mills. Plans may be seen, and specification and form of tender obtained, at the office of the borough surveyor, on payment of a deposit of £2, which will be refunded on the return of the documents and the receipt of a bona fide tender. Tenders, under cover, endorsed "Sewage Works Electric Lighting," must be delivered at the office of Mr. James Leach, deputy town clerk, Town Hall, Rochdale by noon on 12th inst.

Croydon.—Tenders are required for the erection of a chimney shaft and buildings to receive machinery for electric lighting proposed to be built in Factory-lane, Croydon, for the Corporation. The drawings, specification, and form of contract, prepared by Prof. Kennedy, F.R.S, may be seen at the borough engineer's office, 8, Katharine-street, Croydon, and bills of quantities, form of tender, and other particulars may be obtained on payment of £5, which will be returned to every person sending in a bona fide tender. Tenders to be sent to Mr. Saml Jacobs assistant town clerk, Municipal Offices, 8, Park-street, Croydon, by 11 a.m. on 14th inst., endorsed "Tender for Electric Lighting Buildings."

London, N.W.—The Vestry of St. John, Hampstead, invite tenders for the following, among other works and materials, for one or three years, at the option of the Vestry, from March 26: (17) coal and coke (including coal for electric lighting station); (23) oils for machinery at electric lighting station; (24) tools, implements, and other electrical engineers' stores; (25) carbons, lamps, and other stores for electric lighting station; (30) removing ashes from electric lighting station. Forms of tender may be had, and further particulars obtained, on application to the surveyor of the Vestry, Vestry Hall. Tenders, endorsed "Tender for ——" (as the case may be), are to be delivered to Mr. Arthur P. Johnson, vestry clerk, Vestry Hall, Hampstead, by 4 p.m. on February 12 No tender for items numbered 1 to 25 inclusive will be received unless the same be accompanied by £10 in cash or bank-notes (not to be enclosed) as an evidence that the tender is made bona fide, and the amount will be returned to each person whose tender is not accepted, but will be retained in the other case until the contract (and bond, if necessary) are duly signed. Each contractor will be required to enter into a written contract, and, with respect to certain contracts, to provide two good and sufficient sureties in such a sum as the Vestry may determine for the performance of contract. The expenses of preparing and stamping contracts (and bond where necessary) to be paid by the contractor.

RESULTS OF TENDERS.

Glasgow.—The India Rubber, Gutta Percha, and Telegraph Works Company, Limited, 8, Buchanan-street, Glasgow, have secured the contract for a complete installation of electrical machinery for the Glasgow Subway Company, Limited. The

Digitized by Google

contract includes four large high-speed engines and dynamos, 13 electric pumps, the lighting of 15 stations and trains, and the supply of power for the elevators.

Burriana.—For the electric lighting of Burriana for 9,000 pesetas a year there were two applications—viz., Señores Vincente Peyrats Rios and Leopoldo Davalos. The decision was adjourned.

BUSINESS NOTES.

Great Northern Telegraph Company.—For the month of January the receipts were £22,400.

Windsor.—Windsor Castle is being placed in direct telephonic communication with the Metropolis

Southwark (London).—It is proposed to light St. George's (Roman Catholic) Cathedral by electricity.

Islington.—The Lord Mayor has fixed Wednesday, March 4, as the day on which he will open the new electrical station.

Eastern Telegraph Company.—The receipts for the month of January were £78 886, as against £70,674 for the corresponding period of 1895.

Stafford.—The County Council Committee have presented an estimate and recommendation for the electric lighting of the judges' lodgings.

Brisbane.—The existing city tramways have been purchased by a London syndicate, which is converting them into an overhead electrical system.

Barmouth.—The District Council have passed a resolution approving of an application by a local company for permission to light the town with electricity.

Eccles.—The Town Council have resolved to take steps to test public opinion in the borough with regard to the advisableness of lighting the streets by electricity.

Eastern Extension Telegraph Company.—For the month of January the receipts show an increase of £8,738 as compared with the corresponding period of 1895.

Llandudno.—The District Council have engaged Mr. A H. Preece at a fee of 50 guineas to report upon the best scheme for lighting the town by electricity

Hove (Brighton).—The fire brigade are about to memorialise the Urban District Council, asking them to take such steps as are necessary to establish electric fire-alarms for the protection of the town.

Tobermory (Mull).—A scheme has been planned for lighting Tobermory, the capital of Mull, by electricity Aros Falls are proposed as the motive power, and £1,000 of capital is considered adequate.

Address.—Mr. P Speedy, formerly assistant engineer to Mr. A. H. Wood, A I.E.E, 39, Victoria-street, S.W., has set up in business as an electrical engineer and contractor at 55, Victoria-street, S.W.

Liverpool Overhead Railway.—The traffic receipts of this railway for the week ending February 2 amounted to £1,044 as compared with £924 in the corresponding week of the previous year being an increase of £120

Ayr.—The transformers having proved somewhat unsatisfactory, they are to be sent back to London and new ones put in their place. The street lamps have been meanwhile supplied from the low-tension cable instead of from the high-tension wires.

New Company.—The Electrical Appliances Syndicate. Limited, has been registered with a capital of £2,000 in £1 shares. Objects: to acquire any patents, inventions, etc., relating to improvements in electrical appliances, and to develop and work the same

Llanelly.—The Borough Council have decided to ask Mr. Howell to give an estimate of the cost of wiring the town hall, the Athenæum, the market, and several of the leading thoroughfares, and what the annual cost might be expected to be, say, for 10 years.

New Telegraph Cable to Germany.—The Post Office authorities have under consideration the laying of a new cable between this country and Germany to supplement the lines now in use, and thereby to accommodate the increasing traffic between London and Berlin.

Canterbury.—The report of Mr. Robert Hammond, M.I E.E., to whom the Town Council applied for advice regarding the proposal to introduce the electric light into Canterbury, has been received and printed, and was this week issued to the members of the Council.

Harrogate.—A cable for the public and private supply of the electric light has been laid in James street, and the motive power for the generators will be derived from refuse destructors which are intended to be erected on the property of the Corporation at the irrigation farm.

Wilmslow.—At a meeting of the District Council Mr Ross tried to reopen the question of electric lighting by moving that a former resolution postponing the discussion of the question until June be rescinded. After discussion, however, the motion was lost by five votes to four.

Lambeth (London).—The committee of the London County Council have approved the plans submitted on behalf of the Charing Cross and Strand Electricity Supply Corporation, Limited, for the construction of a generating station, iron coal-bunkers, and furnace chimney shaft at 85, Commercial-road.

City and South London Railway.—The returns for the week ended February 2 were £991, compared with £1,021 for the corresponding period of last year, being a decrease of £30. The total receipts for the half year terminating as above were £5,026, compared with £5,020 in the same period of the preceding year, being an increase of £6

Sheffield.—The Parliamentary Committee of the Corporation have been informed that the Sheffield, District, and Rotherham Tramways Company, who proposed to take over the tramway system in Sheffield, had decided to withdraw their Bill from Parliament for this session. The committee decided to enter into negotiations with the company now owning the tramway system.

Cardiff.—Mr. H. J. Hallett, the expert appointed by the Lighting Committee, has commenced his enquiry into the circumstances which led to the suspension by the manager (Mr. Appleby) of one of the assistant engineers employed in the electrical works. The enquiry was private, and, after hearing the statements on both sides, Mr. Hallett decided to visit the works and inspect the machinery.

Birmingham.—The Town Council have given formal sanction to the Central Tramways Company to substitute the electric overhead wire system for the horse traction upon the tramways leased by the committee to the company between Albert-street and Nechells Park-road, upon conditions set out in the Works Committee's report, or such modifications thereof as the committee may think necessary or advisable.

Paisley.—A fire occurred on Monday at Blackstoun Mineral Pit, near Paisley, the property of Messrs. Wm. Black and Sons, Limited. The outbreak originated in the electric machine-house, and afterwards spread to the engine-house. The latter building was entirely destroyed as was also the electric apparatus in the machine house. The total damage caused is estimated at about £1,000, which is understood to be covered by insurance.

Kidderminster.—A special meeting of the Town Council has been held to consider the question of the proposed electric tramway from Kidderminster to Stourport. The General Purposes Committee presented a report relative to the tramway scheme, and it was recommended that the Council, subject to some modification in the plans which the promoters of the Bill had agreed to make should approve of the Bill. The report was adopted.

Dover—At the last meeting of the Town Council, the clerk read a letter from the electric lighting company. asking that the acceptance of the contract with the gas company for the lighting of the whole of streets by incandescent burners might be deferred, at any rate so far as it concerned the streets in which their cables were laid for a fortnight or so, as they intended to submit an alternative scheme for lighting the streets by electric light at a less cost. The matter was deferred.

Edison and Swan United Electric Light Company, Limited.—The directors have resolved that a payment on account of the dividend of the current year be made at the rate of 5 per cent. per annum, less income-tax, on the A shares of the Company in respect of the half-year ended December 31, 1895. This will work out as follows: on the 89 261 partly-paid £5 shares, £3 paid, 1s 6d. per share; on the 17,139 fully-paid £5 shares 2s. 6d. per share. The dividend warrants will be issued on the 18th inst.

Electric Traction in Germany.—It has just been announced, at a meeting of Mayence merchants, that the South German Railway Company of Darmstadt, are going to work the tramways of Mayence and its suburbs by electricity. The same company are also seeking authority to construct and equip electric lines uniting Mayence, Biebrich, and Wiesbaden; Kastal Erbenheim, Nordenstadt, Delkenheim Wicker, and Hockheim-on-the-Main; and Mayence Laubenheim, Bodenheim, Nachenheim, Nierstein, and Oppenheim.

Extraordinary Development of Business.—During the month of January Messrs Siemens Bros. and Co. Limited, of 12, Queen Anne's-gate, London S W. received no less than 38 orders for machines having a total output of 4,200 kilowatts and with a horse power of about 5,700. Of these machines, 15 are for outputs of more than 200 kilowatts each These figures give some idea of the enormous amount of business that Messrs. Siemens are doing. and are an eloquent testimony to the high standard of their workmanship.

Pembroke.—A public meeting of ratepayers will be convened shortly to protest against the Corporation entering into any agreement with a syndicate, which is in course of formation, for the purpose of lighting the streets of Pembroke by electricity. The syndicate is understood to consist of local men, some of whom are members of the Corporation, and they expect to realise a profit of at least 25 per cent. The opponents of the proposal will advocate the desirability of the Corporation taking the lighting of the streets into their own hands.

National Telephone Company.—The directors have resolved, subject to final audit, to recommend the following dividends for the half year ending December 31: At the rate of 6 per cent. per annum, less income tax, on the amounts paid up on the first and second preference shares; at the rate of 5 per cent. per annum, less tax, on the amounts paid up on the third preference shares; at the rate of 6 per cent. per annum, free of tax, on the amounts paid up on the ordinary shares; carrying £35,000 to reserve and about £5,000 forward.

Cork.—The Town Council have decided to engage Mr E. Manville. of the firm of Messrs. Kincaid, Waller, and Manville, electrical engineers, to report, at a cost of £42, upon a suitable site for works and scheme for lighting the city by electricity, and with estimate of capital, cost of maintenance, and revenue. Mr.

Digitized by Google

Manville is also to report on the results of the working of other stations, so as to enable the Corporation to judge whether ir would be advisable for them to undertake the work themselves, ot to lease the provisional order now applied for to a private company

Pitlochry (Perthshire).—Prof. Forbes has submitted to the directors of the gas company a report and detailed estimate of the cost of the proposed scheme for introducing the electric light into Pitlochry. Prof. Forbes estimates that £4,000 would carry out the scheme, which provides for 3,000 lights of 16 c.p. or their equivalent, and states that if the light were fully used a charge equal to a rate of 2s. 6d. per 1,000 cubic feet of gas would yield a profit. Further consideration of the scheme was deferred until the precise terms on which the water power could be had are ascertained.

Fareham.—Mr. Chennell, Q C., having applied to the Queen's Bench on behalf of the Urban District Council for a further stay of execution of the judgment given in December last in favour of the Fareham Electric Light Company, Limited, Mr. Robson, who appeared for the company, consented to a stay for 14 days, intimating that his clients were willing to take interest at the rate of 4 per cent. on the amount of the contract. An order was accordingly made for a stay of 14 days. It is stated that the Local Government Board are willing to grant the Urban District Council permission to borrow the sum of money asked for in their first application, but that any other amount would require further consideration.

Chelmsford.—A letter was read at the last meeting of the Town Council from Messrs Crompton and Co., stating that if the Council favoured the idea they would be happy to forward the price they were prepared to accept for the new generating premises now in course of erection and the whole of the town-lighting plant. Messrs. Crompton further pointed out that the firm contemplated putting up other large works on a fresh site Naturally, these premises would be a benefit and improvement to Chelmsford in two ways, as the money received for the town lighting would be utilised for additional extension and the extra employment of labour. The letter was referred to the Lighting Committee, with instructions to fully investigate the matter and report thereon.

Appointments Open.—The Corporation of Edinburgh invite applications from gentlemen who have had a thorough training both as mechanical and electrical engineers for the post of resident engineer for the central electric light station. It is most desirable that candidates should have had practical experience in central-station working, and also if possible, in the laying of electric mains. Salary £400 per annum. A schedule of duties will be sent by the town clerk on application. All applications should be in the hands of Mr. Thomas Hunter, W.S , town clerk, City Chambers, Edinburgh, before the 17th inst.—We also publish particulars in our advertisement columns of a post as electrical engineer of some works in the country at a salary of £250 a year, with a percentage of the profits.

Leicester.—The Mayor announced at the Council meeting that he had received a letter from a gentleman named Hobbs, who resided on the South Coast of England, and who was trying to induce the Government to undertake the work of effecting telegraphic communication between lightships and the shore. Sir Israel Hart moved that the letter be referred to a committee for consideration, and said all who were interested in maritime matters knew the desirability of electric communication being established between lightships and the mainland. Mr. Hobbs had succeeded in doing it in the case of 50 out of the 250 stations round the coast, and his object was now to bring the question before Parliament with a view to inducing them to undertake the remainder of the work. Councillor Rowlett seconded and the motion was agreed to.

Douglas (Isle of Man).—The movement in favour of lighting the promenade and the principal streets by electricity seems likely to result in the installation of the electric light before next season. The only question to those who support electric lighting is whether it should be entrusted to a company who have tendered to light the front for £1,400 a year, or whether the light should be produced by the Corporation. The consensus of opinion is in favour of the latter. but it is doubtful whether the town would provide its own light, seeing that the initial cost would be about £44,000. A voluminous correspondence has been going on in the local Press on the subject between Mr. E. Berry and Mr. G. Gillmore, the former of whom advocates that if the town is to be lighted with electricity, the Corporation should do the work and take what profit there may be

Glasgow.—The accounts of the Corporation electric lighting department for the year ended December 31 last show that the revenue amounted to £3 611. 8s. 9d., and the expenditure to £1,356. 18s., leaving a balance to be carried to the revenue account of £2,254. 10s. 9d It is expected that the Council will reduce the price of the electric light by a penny per unit. A deputation from the Public Electric Lighting Committee has visited Edinburgh for the purpose of inspecting the electrical installation in the city. They were received by Councillor Mackenzie, convener, and several members of the Edinburgh Electric Light Committee. by whom they were shown over the station at Dewar place Subsequently they were entertained to dinner in the Rutland Hotel, under the presidency of the convener of the Edinburgh Electrical Committee

Derby.—The Electric Lighting Committee estimate that on account of the increasing demand for light it will be necessary to lay a heavy concentric cable in the place of the five pairs of small cables, at a cost of £3,430. Their other estimates are as follow: extension of high-tension feeder mains for Babington-lane, for lighting the technical college, £175; new transformer-chamber for the technical college, £55. 10s.; two 60-kilowatt transformers at £140 each, £280; electric lighting of Babington-lane by placing incandescent lamps in existing gas lamps, £170; six large low-tension switches at £5 each, for extra transformers, £30; estimated cost of making house service connections. including borough surveyor's charges, £310; cost of meters, £250; side tip wagons etc., £17. 10s.; one 1-h.p. motor, worm, and drum, for hauling coal, etc., out of coal-store, £50; sundries, such as holders, switches, lamps, and small cables, £77. 11s.; lathe, £50; service connections to March 31, 1896. £50.

Dublin.—A numerous deputation from the Ratepayers' Association waited on the Council at their last quarterly meeting with reference to the question of the extension of tramways in the city. Mr. Field M P., said that he was there in the interests of an opponent of monopoly, and spoke in an independent position. The classification of signatures to the memorial, it was important to say, included 17 public companies, 131 professional men, 86 merchants, 786 traders, 1,107 owners, lessees, and occupiers, and the total signatures were 5,153. There were 1,400 frontages in the routes traversed by the proposed extension, and not one objection from them had been lodged against the proposed southern tramways, but, on the other hand, nearly the whole number signed the memorial in favour of the Bill. He believed that the electric tram system had come to stay, and there was no amount of opposition that would succeed against it Several other gentlemen also spoke in favour of the Corporation Bill.

Ripon.—At the quarterly meeting of the City Council, the Mayor (the Marquis of Ripon, K G) stated that the Dean and Chapter had agreed to postpone for further consideration the question of lighting the cathedral with the electric light until their July Chapter meeting. They expected then to hear from the Corporation any offer they might have to make, and if accepted it would be with a view to the minster being lighted by October 1. That left the Corporation in the position of having made no offer, and stated no terms to the Dean and Chapter, and of having until their June meeting to carefully consider what steps to take in regard to the question of electric lighting. He was very glad that was the case, and he ventured to recommend that the Gas Committee should take the whole subject into their further and careful consideration, not merely the question of lighting the minster or any other particular section of the city but the whole question of electric lighting in the city, under the circumstances in which they now found themselves. He moved the adoption of the whole of the minutes of the Gas Committee, which were confirmed.

The Waterloo and City Railway.—The work in connection with this railway is being rapidly pushed forward, and considerably more than half the tunnelling work is finished. The line will be about a mile and a-half long, and already communication is completed between a point below the Cannon-street end of Queen Victoria street and another point below Stamford-street. and near the Waterloo-road. The station at Waterloo will be built among the arches underneath the existing South-Western Railway station, while the City station will be at the Mansion House end of Queen Victoria-street The whole of the ground beneath the Mansion House and Royal Exchange-square will be excavated. as the Central London Railway will have its station here. A ring tunnel is to be constructed just beneath the surface of the existing roadways and will communicate with the pavement by five stairways. The railway platforms will be about 58ft below the subways, and they will be connected with the offices by hydraulic lifts. A branch subway will lead to the station under Queen Victoria-street. and all these subways will be open to the public.

Sir Wm. Armstrong and Co., Limited.—The new Company has been registered with a capital of £4,000,000 divided into 200,000 4 per cent cumulative preference shares of £5 each and 3,000,000 £1 ordinary shares, to adopt and carry into effect the agreement expressed to be made between Sir W. G. Armstrong, Mitchell, and Co , Limited (incorporated 1882), and the Company, for the acquisition as a going concern of the business. The first directors are the Right Hon. Lord Armstrong, Sir A. Noble K.C.B., Admiral the Count Albini, William D. Cruddas, Colonel Henry C. S Dyer, Hon. E F. L. Gower, S W. A Noble, George W. Rendel Hamilton O. Rendel Right Hon. Lord Rendel, Henry F Swan, Josiah Vavasseur, Philip Watts, Percy G. B. Westmacott, and Lieut.-Gen. Charles W. Younghusband, C B. An extraordinary meeting of the shareholders of Armstrong, Mitchell, and Co. has been held in Newcastle for the purpose of taking final steps in the reconstruction scheme. Lord Armstrong, who presided, said it was only necessary to confirm the resolutions previously passed relative to the reconstruction, and the resolutions were confirmed accordingly.

Edinburgh.—The Plans and Works Committee of the Town Council have recommended that the police cells should be lighted by electricity. They have given Messrs Siemens and Co. the contract for the engines and dynamos at the electric lighting station, and to Mr. Sinclair the contract for the boilers, at the same price as formerly for similar plant. Councillor Johnston, in moving the adoption of the Gas and Electric Lighting Committee's report, said it was satisfactory to find that, notwithstanding the reduction of the price from 7d. to 6d., there was a favourable balance of £435. The committee recommended that the price should be still further reduced from 6d. to 5d., and they trusted that the reduction would have the effect of increasing the demand for the use of electricity in the city. The committee had likewise thought it advisable to reduce by one-half the charge for meters, which was rather heavy on consumers. Electric lighting had been so successful that the committee had had under consideration the question of still further extending the works at the station, and

Digitized by Google

as regards this they would bring up a report as soon as possible. The report was adopted.

Bolton.—The following proceedings of the Gas and Streets Joint Committee have been approved by the Streets Committee: The sub-committee considered the question of adopting a system of electric traction for the Corporation tramways, and it was resolved that the borough surveyor and the electrical engineer be requested to prepare and present a report upon (1) the probable cost of the installation of the overhead electric driving power of the tramways; (2) the comparative working cost as between horse traction and electric traction; (3) the financial position of the Corporation with regard to the sinking fund on the first cost of the permanent way of the tramways and the additional cost of the overhead electric traction system; (4) the amount of the annual payment for sinking fund and interest combined, and the rent the Corporation would have to receive to make the new system a financial success; (5) the advantages the Corporation and the public might reasonably expect by the adoption of the electric traction; and (6) their general opinion upon any other points thought desirable to be brought before the Corporation on the subject, and that they be authorised to take such steps as they may deem necessary for obtaining the information requisite for the purposes of their report.

Anglo-American Telegraph Company.—The report of the directors of this Company, to be submitted to the meeting to day, states that the total receipts from July 1 to December 31 1895 including the balance of £831 brought forward from the last account, amounted to £165,589. The traffic receipts show an increase of £15 764, as compared with the corresponding period of last year. The total expenses of the half year, including the repair of cables, etc, as shown by the revenue account, amounted to £54,795, being a decrease of £1,056. The directors, under the powers conferred upon them by the articles of association, have, before declaring the net profits, set apart the sum of £12,000 to the renewal fund, leaving a balance of £98 794 Interim quarterly dividends of 10s. per cent. on the ordinary stock, and £1 per cent. on the preferred stock, were paid on November 1 absorbing £35.000, leaving £63,794, out of which the directors recommend final dividends of 18s. per cent on the ordinary stock, and £1. 16s. per cent. on the preferred stock, amounting to £63,000, making a total distribution for the year ended December 31 of £2 9s. per cent. on the ordinary stock and £4. 18s. per cent. on the preferred stock, leaving £794 to be carried forward to the next account The Company's repairing ss. "Minia" has been employed during the past half year in the repair of the 1873 cable, broken off the coast of Ireland, and of three cables between Newfoundland, Cape Breton, and the United States. She has also been employed by the Direct United States Cable Company for the repair of cables belonging to that company. Proceedings in the French lawsuit are still pending.

Leeds.—The Lamp Committee of the Leeds Corporation have decided to erect about 60 new ordinary lamps in different parts of the city. These are to be chiefly placed at Headingley, East Hunslet, Holbeck, and in the east and north wards. The large lamp now being erected in the City-square is to be lighted by electricity. At the top of the post there is to be a large arc light, which will be switched off every evening at 11 o'clock. At the same time the smaller incandescent lamps which are to be fixed on the two arms of the post will be switched on. The committee think this an admirable way of exercising economy. Some people had been bold enough to suggest that the structure would look more pleasing with four arms, but the committee reply that four large incandescent lamps would require as much electricity as an arc light, and therefore they don't see where their desired economy would come in At the Leeds County Court an action has been heard in which William Strafford Milestone, oil and paint merchant, Dock street, Leeds, sought to recover £10 damages from the National Telephone Company for trespass. Mr. Middleton, barrister (instructed by Mr. W. H. Forster), appeared for the plaintiff, and Mr. Middlebrook for the defendants. The plaintiff's case was that on August 15 last the defendants' men invaded his premises in his absence and proceeded to fix a telephone wire. On the plaintiff arriving and remonstrating with them, the foreman admitted that he had made a mistake and should have gone next door. Plaintiff had some valuable young homing pigeons, which were frightened away. His Honour found that the pigeons, which were worth 10s, had been lost, and he gave a verdict for five guineas, and certified for counsel.

Peterborough.—The Electric Lighting Committee of the Town Council have considered very fully the electric lighting question. At their last meeting they decided that the Corporation should apply to the Local Government Board for sanction to borrow the sum of £20,000 for the purpose of carrying out the scheme of electric lighting in the scheduled area of the borough. An amendment had been moved to this resolution, but was lost. The purport of the amendment was that having regard to the suggested great increase beyond the original amount estimated, the Corporation should offer to dispose of their powers under the provisional order to a company. The committee's action came before Council at their last meeting for approval. Alderman Percival said he objected to the resolution on the ground that the undertaking had not met with sufficient commendation, that the estimates were not reliable, the scheme was likely to incur a much larger expense than had been estimated, and, further, that the proposal in itself was very unfair to the general body of ratepayers. They proposed to borrow £20,000 upon the faith of the estimates of two gentlemen whose original estimate for the work was £12,000, which increased to £14,000, and jumped up to £20 000, with the information that these were not to be considered close estimates, or even estimates that were likely to be acted upon, because other alterations would be made. Mr. J. Hunting said in Peterborough they had had quite enough experience of the effects of monopolies, and they did not want the town to suffer by allowing a company to take over electric lighting. The estimates had been prepared by their engineer, and in all other cases they had been able to confide in his work. The minute of the committee was adopted by 11 votes to 6.

Preston.—There was a lively discussion at the Council meeting on the Streets and Buildings Committee's report, which contained the following recommendations: That the schedules of bills from this committee amounting to £2,152. 15s. 7d., £1,955. 10s. 9d., and £72. 19s. 4d., be passed for payment. That 30 electric arc lamps be placed in Lancaster-road, Corporation-street, Cheapside, Friargate, Lune-street, Fleet-street, Birley-street, Market-street, Orchard-street, Fishergate-hill, and Fishergate, as shown on the plan now submitted, and that the same be lighted by the National Electric Supply Company, Limited, together with the arc lamps at present in Fishergate, making a full total of 42, on the terms set forth in the company's letters on January 14 and 17, 1896—viz, to light the arc lamps of 500 c.p. each for 3,535 hours per annum for the sum of £14. 10s. each per annum, the company to find the lamps and carbons, clean and trim the same, and turn the lamps on and off Councillor Pearson, in moving the adoption of the report, said that, assuming all things to be equal, and that gas lamps were to be lighted 3,335 hours, the cost then would be £565. 18s 9d., or the difference between electricity and gas would be £43. 7s. 5d. But when they came to examine the candle-power they saw an immense difference. The 42 arc lamps, each of 500 c.p., would give a total candle-power of 21,000. The gas lamps, assuming that each gave 36 c.p., would only give a total of 3,406, so that they should have something like 17,540 additional candle power by electricity, and at a cost of £43. 7s. 3d. This practically meant that they got six times the quantity of light from the electric arc lamps. Eventually the report was adopted by 18 votes to 11.

Town and Village Company.—Under the title of the Town and Village Electric Light and Power Company, Limited (Parfitt's Patents) a company has been formed, with a capital of £100,000, divided into 19,800 ordinary shares of £5 each and 1,000 founders' shares of £1 each, for the purpose of acquiring letters patent granted to Messrs G. J. and G. J. T. J. Parfitt for the United Kingdom, for "an improved method of electric lighting in series, and apparatus therefor," together with the freehold land, plant erected thereon, stock-in-trade, and existing contracts of a syndicate now working the system; letters patent in respect of the same invention for the United States of America, the Empire of Germany, and the Dominion of Canada; and letters patent granted to Mr. G. J. T. J. Parfitt for the United Kingdom for "indicating light failures in electric lighting circuits, and apparatus therefor." The purchase price has been fixed by the vendor at £31,000, payable as to £8,200 in cash, £20,000 in fully-paid ordinary shares, £1,000 in fully-paid founders' shares and the balance of £1,800 in cash or ordinary shares, at the option of the Company. Of the ordinary shares 15,440 are offered to the public at par. In reference to this, the *Financial News* says: "If the Company succeeds in raising the capital it requires, we shall probably see before long a very considerable extension of electric lighting in provincial towns and villages. The Company proposes to acquire and work the Parfitt patents, which have been tried with success at Keynsham and Kingswood, and which, according to Prof. Silvanus P. Thompson, are both economical and effective. The Board of Trade return shows that the lighting of Kingswood is the cheapest in the United Kingdom, the rate made being only 2½d. per unit, and the cost being cheaper than gas."

Blackburn.—The town clerk (Mr. R. E. Fox) has issued his report upon the legal position of the Corporation, and as to the general effect of the tramway company's proposal: that the Corporation should, upon terms to be arranged, put down at their own expense the necessary plant for supplying the tramway company with electricity, and should also, at their own expense carry out the necessary works in bonding the tramway rails and erecting posts and other apparatus, and also provide electrical tramcars. The town clerk says that subject to the consent of the Local Government Board the Corporation have to borrow the capital necessary to enable them to put down the requisite machinery for providing the trams with electricity, but, seeing this does not apply to the purchase of tramcars, he does not think the Council should entertain that proposal. He has had an interview with the chairman of the tramway company, who "does not think there will be any insuperable difficulty on the part of the company in raising the necessary funds for this purpose themselves." The capital required by the Corporation is put at £13,000, and, taking the term of repayment as 15 years, the annual interest and sinking fund would be £1,089. In the opinion of Mr. Lacey the cost to the Corporation of production of electricity, including capital expenditure, should not exceed 2 5d. per unit, and that the total cost of working to the company would be 6d. per annum per mile, reducible by an increase of traffic. Assuming that the company were supplied by the Corporation with electricity at cost price, the annual cost to the company would be £4,725, while the average annual cost to them during the last three years has been about £6,187 showing a net annual saving to the company on electricity of £1,462 per annum.

Belfast.—The following report has been discussed by the Corporation: "The Belfast Street Tramway Company are promoting a Bill in Parliament authorising the use on their tramways of

Digitized by Google

mechanical power, including electrical power, either carried in the carriages or generated in or applied from stations, steam power, locomotive, or stationary, and haulage by means of wire ropes, cables, or chains, or other appliances for the purpose of moving carriages and trucks, also for the laying down, construction, and erection of all machinery, plant, and works requisite for this purpose. Your committee are of opinion that such powers would seriously affect the interests of the ratepayers, and having had the report of the town clerk on the Bill (copy of which is appended hereto) before them, they have instructed him to have a petition presented against the Bill. Your committee consider it very desirable that the best information procurable on the subject of the electric traction in connection with street tramways should be obtained for the guidance of the Council, and they have, therefore, appointed the Lord Mayor, Alderman M'Connell (chairman of the Improvement Committee), and Councillor Andrews (chairman of the Electric Committee), with the town clerk and surveyor, to visit some of the chief cities and towns on the Continent where electric traction is used on street tramways, and to ascertain full particulars thereof, and to report to the Council thereon. The tramway company have also given notice of an application to the Privy Council for an order authorising the doubling of all their lines. The matter will require the careful consideration of the Council when the application comes before them, and should before that receive attention from the Law and Improvement Committees. Your committee have had interviews with several deputations from the districts proposed to be added to the city under the Bill promoted by the Council; but as definite arrangements have not yet been come to, they are not in a position to report the result, but hope soon to do so." The report was adopted, with the addition of the names of Alderman Lawther and Mr. M'Cowen (the electrical engineer of the city) to the deputation.

Liverpool.—At a meeting of the Waterloo District Council Councillor Killey moved, "That an agreement be entered into with the electric light company now promoting a Bill to enable them to supply the district with the electric light, embodying the terms agreed upon between the Parliamentary Committee of the Council and the company." Councillor Killey said they had secured very favourable terms, much better than those originally proposed by the company. The maximum price to be charged to ordinary consumers had been reduced from 1s. to 9d. per unit, the number of streets proposed to be lighted had been increased, a revision of prices would be made every three years, no site for a generating station could be utilised without the approval of the Council, and the charge for electricity for public purposes was fixed at two-thirds of the price charged to ordinary consumers. The resolution was passed. Mr. Charles Rettie has written to the *Journal of Commerce*, saying that at the last meeting of the tramways company the chairman made a remark that they had received an estimate to run the cars in Liverpool on the storage system, but as they wanted 7d. per car mile it was out of the question to adopt electricity on these tramways, as the cost of the horse-cars was only 5d. Mr. Rettie states that, though the above is quite correct, it is not generally known that the contractors were only asked to run 12 cars. If they had been asked to run the whole of the cars, which at that time were 245 in number, they could have run them far cheaper than by horses. The heavy gradients, he says, certainly make the working experiences of the tramway system greater than at Manchester and Glasgow, which places are very flat, but that is all the more reason why electricity should be used in a place like Liverpool for the tramways in preference to any other system. At a meeting of the Waterloo Parish Council, the deputy clerk said a letter had been receive from the County Council concerning the Ashton, Hyde, and District Electric Tramway, stating that they had been in communication with the Cheshire County Council with reference to the order sought to be obtained by the company, especially in regard to article 17, which related to the company having power to lay such posts and overhead electric wires in the streets as might be necessary for the working of the tramway. The construction of the tramway would affect many county bridges and roads, and the County Council, before taking steps to oppose the order, would be glad to have the opinion of the Waterloo Council upon it. It was decided to reply that, as the tramways would be of so much use to the inhabitants, they saw no reason for modifying the scheme.

Maidstone.—The Town Council have decided to dispose of their provisional order to a company. On March 14, 1894, the following resolution was adopted: "That this authority take the requisite proceedings to carry out the Maidstone Electric Lighting Order, 1892, by transferring the same to a private company on terms to be arranged by this authority, and sanctioned by the Board of Trade." At the last meeting Mr. Walter Cox moved the rescission of this resolution, and said it would be desirable they should keep the order in their own hands. He maintained that this was desirable, not only in the interest of the present ratepayers, but in the interest of those who would follow them. It was not right to yield up to a public company the order, as they would thus be creating a monopoly, and it would be a monopoly giving up all control of the order to a public company. He pointed to the Dover company and Rochester, the former of which, notwithstanding what he had mentioned about bartering with the shares, etc., were able to pay 20 per cent. dividend. He maintained that the scheme could be made to pay, for electricity was now out of its experimental stage. He was not asking them to carry out the order themselves at present, but simply to hold their hands so that they would be free to act at any time. It was decided by almost a unanimous vote to obtain the order, and he hoped by a unanimous vote that day they would decide to keep it. Mr. Corke seconded the resolution. Mr. Baker spoke against it, and said he was talking to an electrician the previous day, and he told him that electricity had not fully developed yet, and if they decided to carry out the order now they would have to do everything fresh at some future time. Considerable discussion took place on the resolution, which was, however, lost by 12 votes to 10. The consideration of the Electric Lighting Committee's report was deferred till next meeting. A company is being promoted by Mr. King who proposes to use the electricity not only for lighting, but for driving purposes. For the district he proposes to light, the works will cost about £25,000 or £30,000, the area of supply extending from Sittingbourne road to Barming and Tovil. The order embraces the whole of Maidstone, but the compulsory area comprises only High-street, Bank street, Week-street (as far as St. Faith-street), St. Faith-street, and along the Fair Meadow. The figure he proposes is about 6d. per unit at the commencement. The current will be conducted along underground wires and worked on the three wire system, probably under the new Board of Trade Act, which permits a house supply at the rate of 200 volts.

Bedford.—The Electric Lighting Committee have reported to the Town Council: "(*a*) That the work of public lighting is proceeding satisfactorily, and they hope that by the date arranged the standards will have been erected and the lamps lighted. The committee propose to have the gas standards, in the area in which electric standards have been placed, removed, and they recommend that it be left in their hands to make all arrangements for this purpose and to carry them into effect. (*b*) That a letter has been received from Messrs Sharman and Trethewy calling attention to the manner in which the electric cables were being laid, and that in River street the gas-mains were exposed, and saying that the gas company would not consider themselves responsible for any danger or damage that might be caused. The committee recommend that the gas company be requested (1) to permit the authority to take a tracing of their maps showing the position of the existing gas-mains, service pipes, and other underground works; (2) to give to the authority not less than three days' notice in pursuance of the Bedford Electric Lighting Order, 1890, before commencing to dig or make any trench for laying down or constructing any new mains or pipes or other works near to which any lines or works of the authority have been placed so as to protect from injury every main, pipe electric line, or work, and for securing access thereto. The electrical engineer has been considerably hampered with the street work owing to his not having a copy of the said map to refer to and also to the fact that he has in many instances discovered considerable underground leakage from the gas-pipes, etc., necessitating the immediate attention of the gas company. (*c*) That they have considered the question of extending the electric mains during the present year, and recommend that the authority borrow a further instalment of £12 000 on account of the loan of £27,000 already sanctioned for carrying out the following scheme: Public lighting only—St. Mary's, St. John's, all streets east side of Hitchin Railway, £1,000 Private lighting only—Bromham-road, Union-street, Ashburnham road (northern half) Goldington-road (to Bower-street), Rothesay road and gardens, De Parys-avenue (northern part). Park-avenue, Embankment (Newnham road to Bushmead-avenue) Kimbolton-road (to St. Augustine's-road), £8,750; machinery at central station, £2,500; contingencies, £250. Total estimated cost £12 500." Some debate followed on the consideration of this report, and with regard to Clause (*c*), Alderman Richards explained that it was necessary to prepare for private lighting before the street lighting. The public lighting could be easily carried out afterwards. Mr. Miller pointed out that the proposed expenditure would bring up the total to £40,000, and few of the ratepayers knew this. Although he acknowledged Mr. Johnston as a capable, practical man, yet he thought it would give more confidence to the ratepayers if the authority consulted an experienced electrical engineer as to whether they were proceeding on the right lines. He suggested that the matter should be held over until the committee presented a statement to show whether the electric light was being worked profitably. On the other hand, Mr. Taylor thought the light should be extended all over the town. The Clerk said the authority were bound to publish a full statement of the accounts relative to the electric lighting once a year, and they would have to be published before March 25. Alderman Richards said there would still be £4,500 left out of the loan sanctioned by the Local Government Board. It had been impossible to prepare a balance-sheet at present, but it would be submitted at the earliest opportunity. The report was adopted.

PROVISIONAL PATENTS, 1896.

JANUARY 27.

1848. Improvements in electric velocipedes and other vehicles electrically driven. Charles Adams-Randall, 1, The Avenue, Bedford Park, London.

1860. Improvements in the method of and means for protecting electric lamp fittings from corrosion and for preventing "short-circuiting." Joseph Lomax Kendal, 5, John Dalton street Manchester.

1867. Improvements in apparatus for straining electrical conductors in culverts. Sydney William Baynes, 33, Haverstock hill, London.

1888. Improvements in dynamo-electric machines. Sebastian Ziani de Ferranti, 27, Charterhouse-square, London.

Digitized by Google

1905. Improvements in furnace-blasts, and in process and in means or apparatus for electro-thermally treating materials, for the reduction of metals, production of carbides, acetylene, cyanogen, cyanides, nitrides, and the fixation of nitrogen. Hudson Maxim, 45, Southampton-buildings, Chancery lane, London.

1927. Improvements in electric railway systems. Moses Lindley Wood, 31, Southampton buildings, Chancery-lane, London.

JANUARY 28.

1958. Improvements in and relating to electric gas-lighters and extinguishers and the like. James Tarbotton Armstrong and Carl Gustaf Georg Braunerhjelm, 64, Aldersgate-street, London. (Complete specification.)

1963. A new or improved electrical switch. Samuel Glover, 70, Market-street, Manchester.

1979. Improvements in conduits for conductors of electricity. William Henry Lane, 52, Halliford-street, Essex-road, Islington, London.

1992. Improvements in electric arc lamps. Ernest John Bagnall and George Arnold, 18 Buckingham-street, Strand, London. (Complete specification.)

2003. Improvements in telegraph repeaters. Henry Harris Lake, 45, Southampton-buildings, Chancery-lane, London. (Benjamin Frederick Merritt, United States.) (Complete specification.)

2029. An improvement in electric glow lamps. Richard Bruno Roxby, 53, Chancery-lane, London.

2043. Improvements in multiple telegraphy. Thomas Bullitt Dixon, 18, Southampton buildings, Chancery-lane, London (Date applied for under Patents etc. Act, 1883 Sec 103, September 12 1895, being date of application in United States.) (Complete specification.)

JANUARY 29

2051. Improvements in electrical resistance thermometers. Henry Robert John Burstall and Henry Frederick William Burstall, 76 King's-road, Camden-road London

2053. Improvements in so-called unipolar dynamos for generating continuous electric currents, applicable also to continuous-current motors and continuous-current transformers. Leopold William Heath, 21, Brunswick street, Chorlton on Medlock, Manchester.

2056. Improvements in and connected with magneto-electric machines for electrically lighting cycles and other vehicles. Robert Bryan Hayme-, Henry Edward Charles Walcott, John Bruce Collier, and Edwin George Bryant, Upper Terrace road, Bournemouth

2074. Improvements in the construction of lamp and bracket reflecters for electric, gas, and other lights. John Parker, Sunbridge chambers Bradford.

2106. Improvements in lightning dischargers for electrical installations. Siemens Bros and Co., Limited, 28 Southampton-buildings, Chancery-lane, London. (Siemens and Halske, Germany.)

2107. Improvements in telephones. John Imray, 28, South ampton-buildings, Chancery-lane, London. (La Société Anonyme pour la transmission de la force par l'Electricité, France.)

JANUARY 30.

2161. Improvements in apparatus for conveying electric current from overhead conductors to motors on tramways or like vehicles. Philip Dawson, 47, Lincoln's-inn-fields, London.

2176. Preserving meat by the help of electricity. Adel Barreto Pinto, 97, Newgate-street, London. (Complete specification.)

2194. Improved means, applicable for use in electric arc lighting, for regulating the distance between the carbon points. Otto Bondy and Albert Jordan, 191, Fleet-street, London.

2197. An improvement in the preparation of electrolysed chloride solutions for disinfecting and like purposes. Eugene Hermite, Edward James Paterson, and Charles Friend Cooper 28 Southampton-buildings, Chancery-lane, London.

2199. Improvements in apparatus for transforming alternating into continuous electrical currents, or conversely. John Imray, 28, Southampton-buildings, Chancery-lane, London. (La Société Anonyme pour la transmission de la force par l'Electricité, France.)

2224. Improvements in prepayment mechanism for electrical or other meters. Charles Orme Bastian and Herbert Cecil Hodges, 31, Southampton buildings, Chancery-lane, London.

JANUARY 31.

2248. Improvements in electrical cut-outs. Hugo Hirst, 88, Queen Victoria-street, London.

2254. New or improved electrical appliance for extracting broken drills from boreholes. Frederick Walker and Walter Callis Sanderson, The Arcade, Barnsley.

2285. An improved method of manufacturing refined bitumen for asphalte, electrical, and other purposes. Charles William Bradshaw and Herbert Antonio Henry Moore, 40, Chancery-lane, London.

2249. Improvements in and connected with fuses for electrical cut-outs. Hugo Hirst, 88, Queen Victoria street, London.

FEBRUARY 1.

2324. An improved electric coupling. John Henry Tucker, 16, Oozells-street, Birmingham.

2328. Improvements in hanging lamps for gas, oil, or electric light. Joseph Benjamin Bruce, Ernest-street, Holloway Head Birmingham.

2335. Improvements applicable to electric meters. William McWhirter, 87, St. Vincent-street, Glasgow.

2337. Improved means for use in working apparatus by electricity. Gaston Emmanuel Sautter and Henri Harlé, 47, Lincoln's-inn fields, London.

2348. Improvements in electric switches. Jan Meines Huisman and Henry Charles Gover, 62, St. Vincent street, Glasgow.

2382. Improvements in dynamometers. Henry Harris Lake, 45, Southampton-buildings, Chancery-lane, London. (George Washington Lewin, United States.) (Complete specification.)

NOTES.

Indian Lighting Rules.—The Electric Lighting Bill passed by the Bengal Legislative Council has received the assent of the Governor-General in Council, and the new Act as well as the draft rules have been published in the *Calcutta Gazette*.

Electricity v. Steam.—According to the New York *Electrical Engineer*, the Cleveland, Akron, and Columbus Railroad Company has taken off its road four passenger trains on account of the electric line competition between Cleveland and Akron.

Anniversary.—Lord Kelvin will shortly attain the fiftieth anniversary of his induction to the Chair of Natural Philosophy in Glasgow University, and steps are being taken to celebrate the jubilee in such fashion as will mark the high appreciation in which the venerable physicist is held.

Amazon Telegraph Cable.—The cable communication between Para and Manaos, the capital of the province of Amazonas, has been successfully completed, and messages of congratulation have been exchanged between the directorate of the Amazon Telegraph Company in London and the Brazilian Government.

Finsbury Technical College.—The students of the City and Guilds Technical College, Leonard-street, Finsbury, will hold their biennial conversazione on Thursday, February 20, when Prof. Silvanus P. Thompson, D.Sc., F.R.S., will lecture on "Invisible Light and its Photography." The programme also includes a concert and dance, while the whole of the college not used in the entertainment is to be given up to exhibits of model machinery, electrical appliances, and chemical manufactures.

Safety Device.—The *Electric Railway Gazette* contains a description of a device designed to prevent accidents which has been invented by Mr. A. K. Bonta, chief engineer of the North Hudson County Railway Company, of Hoboken, New Jersey. The principle is the arrangement about the steam-engines of a system of air-pipes provided with glass air-tubes, which, when broken, allow the compressed air to escape. The reduction of pressure then brings into action a valve, and shuts off steam from the engines. The pressure is maintained in the air-tubes by a pump of the Westinghouse air-brake type.

Telephoning a Wreck.—When the American liner "St. Paul" went ashore at Long Branch, the New York and New Jersey Telephone Company promptly fitted a telephone line from the shore to the stranded ship. The New York *Electrical Review* describes the line, which was part of an emergency stock kept by the company, and states that conversation was successfully maintained and business was brisk over the line. The "St. Paul" was entered in the company's directory as "No. 125 Long Branch." The above may be taken as a fair example of what private enterprise will do.

American Trolley Patents.—The United States Circuit Court of Appeals, on reviewing Judge Coxe's Elmira decision relating to the Van Depoele patent on overhead trolley devices, has given a judgment reversing some of the points sustained by Judge Coxe. The claims for a combination with an overhead conductor arranged to receive a travelling underneath contact of a switching device secured to and depending from the conductor, have been declared void, owing to lack of novelty. The claims embracing among their constituents an overhead wire and a grooved contact device or devices, and the claims relating to the trailing trolley and relative arrangement of trolley switches and branch switches, are sustained.

Electric Towage.—A full text of the report of the State authorities as to the electric towage experiments made recently on the Erie Canal is printed in the *Western Electrician*, and gives further details than have hitherto been available. It is stated that the tests were not made under the best conditions, the E.M.F. varying considerably, and the power developed by the motor averaging only about one-third of its capacity. Nevertheless the results go a long way towards demonstrating that electric towage is practicable and full of promise in point of economy. With the vessel used the average speed was 2·5 miles per hour, requiring 8·5 e.h.p. for the 117·5 tons towed, and the price is worked out to be far short of the present cost of towage.

Society of Chemical Industry.—At a meeting of the Nottingham section of this society, Mr. L. Archbutt, F.I.C., made a communication on the ignition of sawdust by nitric acid, in which the author gave an account of experiments made to find out what danger attaches to the usual way of packing bottles containing this acid in sawdust when delivered for transit to the railway company. On a complete breakage, in one case, ignition occurred readily, the mass of sawdust bursting into flames, and in all cases, even with comparatively weak acids, danger was apparent. Mr. Archbutt said that he would recommend the use of kieselguhr, or some similar absorbent material, for the safe packing of bottles containing dangerous acids. No doubt this would be the best way if everyone stored kieselguhr, but they do not. On an emergency, why not try sand?

Construction Rules in the States.—The meeting of the representatives of various American electrical associations who have been invited by the National Electric Light Association to consider the adoption of a standard set of rules for electrical construction and operation is to take place on March 18. The bodies asked to send delegates are the American Institute of Electrical Engineers, the American Street Railway Association, the National Board of Fire Underwriters, the International Fire Chiefs' Association, the American Institute of Architects, the American Bell Telephone Company, the Western Union Telegraph Company, the Postal Telegraph Company, the General Electric Company, and the Westinghouse Company. The delegates are to form a committee with a view to securing the promulgation and enforcement of one standard set of rules for electrical construction and operation.

Niobium Filament Lamp.—Inventors show no inclination to rest satisfied with carbon as the material for incandescent lamp filaments, and the New York *Electrical Engineer* describes a new lamp due to Mr. J. W. Aylsworth, of Newark, New Jersey. In this case the incandescent conductor is made from such refractory metals as niobium, tantalum, molybdenum, titanium, or zirconium, and the method by which the filament is prepared consists in heating a base or support in the vapour of a volatile halogen compound of the element which it is desired to deposit, simultaneously mixing with the vapour a reducing gas, such as hydrogen. Mr. Aylsworth has succeeded in depositing in this manner tantalum, niobium, molybdenum, titanium, and zirconium, continuing the process in each instance until the carbon core or other conducting filament is surrounded by the metal. It is stated that a niobium lamp prepared in this manner has been run on test for some months past and shows very high efficiency and long life.

East of Scotland Engineers.—At the meeting of the East of Scotland Engineering Association at Edinburgh,

Digitized by Google

Prof. Armstrong in the chair, Mr. A. R. Bennett read a paper, in which he remarked that several important facts connected with the telephone question had recently been presented in a manner which advocates of the existing state of matters in the United Kingdom had not seen their way to challenge. These facts included the smaller rate of subscription paid in foreign countries to that in the United Kingdom; that the greatest degrees of development were attained by means of local enterprise; that the telephone was put to more numerous uses abroad than in this country; and that competition between two telephone companies within the same area had a stimulating effect on the growth of telephone work. He argued that the policy of the Post Office did not tend to improve matters, and then showed how easily private companies might be formed.—Mr. D. M. Stevenson has also been enforcing somewhat similar views before the Glasgow Chamber of Commerce.

Electric Fish.—M. d'Arsonval has communicated to the Société française de Physique the results of his experiments with the electric ray. The curve of the discharge is very similar to that of the contraction of a muscle—namely, a rapid increase of the ordinates followed by a slower decrease. But the curve contains indentations showing that really there are several discharges—the usual number is eight—with a total duration of ·1 to ·15 of a second. With an open circuit a difference of potential exceeding 300 volts can be measured between the dorsal and ventral surfaces of the electric organ, but measurements of the discharge indicate a much lower effective voltage. The discharge can only be repeated a few times in succession, after which a period of rest is necessary. The analogy between the cells of the electric organ and the elements of a voltaic pile is apparent only. No electric effect is obtainable without a muscular contraction, and M. d'Arsonval considers the cause must be sought in a variation of the contact surfaces in the cells of which the organ is composed, and he refers to some experiments of M. Lippmann on this point.

Endowment of Research.—In connection with recent electrical researches at the Bengal Presidency College Laboratory, the Provincial Government has made a grant of Rs.1,000 to defray the cost of a more elaborate form of apparatus devised by Prof. J. C. Bose for his experiments. The Government has also established a permanent "science research fund" for the continuation of these researches. An astronomical observatory will shortly be constructed, where the splendid telescope by Grubb, recently presented to the physical laboratory by his Highness the Maharaja of Tippera, will be installed. An important work undertaken by Mr. Bose is the continuous record of the variation of three elements of terrestrial magnetism. The construction of a complete magnetic observatory equipped with the latest pattern of Kew instruments has been sanctioned by the Government, and will be soon taken in hand by the Public Works Department. The frequency and intensity of magnetic storms, and their connection with terrestrial and solar disturbances, will be among the problems that will be specially studied. The absolute value of the horizontal magnetic force of Calcutta is being determined from a series of observations extending over the past three years.

The Patent Office.—Mr. Kenric Murray, secretary of the London Chamber of Commerce, has written to Sir Henry Reader Lack, the Comptroller-General of the Patent and Trades Mark Office, calling attention to the fact that the librarian of the Patent Office of the United States of America is making a collection of illustrated and other trade catalogues, price-lists, circulars, and similar publications for reference by those instituting enquiries in regard to patents, designs, and trade marks, or making use of the Patent Office library, and suggesting that such a collection of records at the English Patent Office would be exceedingly valuable, as by this means there would be permanently preserved an enormous amount of extremely useful material which might on occasion elucidate the meaning of many trade terms and usages. Sir H. R. Lack has replied as follows: "I beg to acknowledge the receipt of your letter of the 27th inst., suggesting, on behalf of the London Chamber of Commerce, that a collection of illustrated and other trade catalogues, price-lists, and similar publications should be made and filed in the Patent Office library, and, in reply, to inform you that the nucleus of such a collection was formed some 20 years ago, and has since that date been gradually extended. In view, however, of the suggestion of the London Chamber of Commerce, I shall be happy to consider how far it may be possible to render this collection more complete and to make it more easily accessible for public reference."

France.—From the statistics of electric lighting and power stations in France compiled and published by *L'Industrie Electrique*, it appears that at the end of 1894 the number of these stations, excluding those in Paris, was 328; by the close of 1895 it had risen to 438. Of these, 378 furnished returns as to horse-power; the highest figures being for steam, 26,802 h.p. at 126 stations. Producer gas is used at six stations, furnishing 208 h.p.; and ordinary gas at 13 stations, giving 1,605. There is one 12-h.p. petroleum plant. The number of water-power stations exceeds that of steam, being 182, but the aggregate horse-power is only 11,665 h.p. There are 48 mixed plants. Alternating currents do not at first sight make a very good show, since these are used only at 75 stations, and to an aggregate of 14,927 h.p., as against 295 stations and 31,955 h.p. for continuous currents. Four stations use polyphase currents to an aggregate of 850 h.p. It must, however, be noted that many of the stations returned are very small ones; and consequently a comparison with, say, the electric supply companies and corporations in England would be quite fallacious. With the addition of the Paris stations and those from which returns could not be obtained, it is estimated that the whole of the French generating stations would show an aggregate of 65,000 h.p. With reference to stations in progress or projected, our contemporary gives up the attempt to tabulate them, with the remark that "they are too numerous."

Choosing a Motor.—Dr. G. H. Zahn, writing on this subject in the *Western Electrician*, discusses the various points which should be considered in the selection of a machine. It should be noted at what load a motor commences to spark, at what load the temperature rises abnormally, what the efficiency is at different loads, and at what speed it runs. It is most important to consider whether the motor is to be run generally at full load or at less than its full load; in the former case the efficiency curve should have its maximum at full load, and in the latter at about the usual load at which it is to be run. In reference to the use of generators as motors, Dr. Zahn remarks that "it is generally known that a good generator will give good results if used as a motor. This holds good if the machine be running under suitable conditions, as considered above—*i.e.*, if it be chosen with a view to the kind of work to be performed and its efficiency at different portions of the load. But if a lighting dynamo is used as a motor its available brake horse-power will be some 30 per cent. less than the belt horse-power to run it as a generator, and the speed will be about 10 per cent. less than that given for the dynamo. The nature and conditions of the work the motors have to do are so various that they cannot

Digitized by Google

be standardised in the same way that the lighting dynamos can. There are three classes of lighting dynamos, according to the winding of the magnets—the series, shunt, and compound-wound machines. But there are many ways of winding the field magnets of motors, each adapted to a particular purpose." It is added that small multipolar machines have no advantage over bipolar ones.

Motorcarts.—The Self-Propelled Traffic Association desire to point out that they are in no way connected with the newly-formed Motorcar Club. The president of the association is Sir David Salomons, Bart., and among an influential council the names may be noted of Sir Frederick Bramwell, Bart., Sir Albert K. Rollit, M.P., Right Hon. G. Shaw-Lefevre, Prof. Boys, Messrs. A. Siemens, Rucker, and G. J. Jacobs (president of the Institute of British Carriage Manufacturers). The association sent an influential deputation to Mr. Chaplin on Wednesday upon the subject of amending the Locomotive Act, or of introducing a new Bill to facilitate locomotion on highways, when Sir David Salomons pointed out to the right hon. gentleman that horseless carriages had recently been introduced on the Continent with great advantage to agriculture, and explained that it was only the state of the present law that hindered their adoption here. Mr. Thornton, of the London County Council, said the Highways Committee of that body were very anxious that these vehicles should be introduced into the Metropolis, as they would be a great boon in congested thoroughfares, seeing that they would take up much less space than carriages drawn by horses. Mr. Chaplin stated that he was fully in sympathy with everything said by the deputation. A Bill was now being prepared by the Local Government Board, and he hoped, with the assistance of Mr. Russell, to carry it without opposition through the House this session. In connection with this subject, it may be added that the *Imperial Institute Journal* states that arrangements have been made for holding an international exhibition of motor carriages at the institute from May to August next. The latest developments of motor carriages supplied by the agencies of oil, steam, electricity, or compressed air will be shown. The allotment of space and the control of the display will be undertaken by the Motorcar Club.

Electricity in Collieries.—At a meeting of the South Staffordshire and East Worcestershire Institute of Mining Engineers, Mr. I. Meachem, jun., supplemented his paper read at a former meeting on "The Electric Power Plant at Haden Hill Colliery." He said the installation had now been at work about six months, and it was possible to judge of its merits. The total cost of the installation was £2,289, while a steam plant would cost £1,089 less, but, on the other hand, they had the advantage of light and a saving of £73 per annum in candles, and a saving of £30 per annum in the lights on the bank. Altogether there was a saving of £102 per annum. The result of the change, according to their sheets, showed a net reduction of cost equal to 3½d. per ton, or on the output £40 a week. They had therefore every reason to be satisfied with the result of the experiment. Mr. Henry Lea, who opened the discussion, said he had inspected the Haden Hill installation. The working of the underground plant certainly was everything that could be desired. The simplicity of the arrangements and the ease of control were very striking. There was, of course, the absence of heat and leakage of steam and condensed water, which would have been met with if there had been a steam-engine in the mine doing the same work. The Chairman said he had yet to be convinced, although he had a 60-h.p. plant in work, that steam-engines fixed on the surface and ropes taken down the shafts could be beaten. In reply to the chairman, Mr. Meachem said that the cost of labour in connection with the installation was ·47d. per ton. Mr. Brown said there was no doubt electricity would not compete with rope haulage for short distances, but where long distances had to be dealt with electric haulage was a considerable advantage. It was quite possible to prevent the dangers arising from sparking, even though the machine might be sparking in the midst of explosive gases. Motors were now made so that they could work with them wherever they could work with a safety-lamp.

Technical Education.—We have received this year's (1896) programme of the Technical College, Exhibition-road, South Kensington, in connection with the City and Guilds of London Institute. It may be noted that the college continues to maintain its reputation, and that the number of students applying annually for admission largely exceeds the number than can be taken. It follows that the matriculation examination, which is held on September 21 this year, is not a matter of form, as is too often the case in kindred institutions; and only those students likely to profit by the course of education are allowed to pass, so that a high standard is maintained. The number of scholarships to be competed for on matriculation is increasing. These consist of one Clothworkers' scholarship of £60 per annum and free education; three Institute's scholarships, each covering the cost of education; one Siemens's Memorial scholarship of £50 per annum for three years—this is awarded every third year, the next award being in 1897; one Mitchell scholarship of £40 per annum with free education, to be awarded to holders of Mitchell scholarship at the Central Foundation School or at the Finsbury College. There are also five Clothworkers' scholarships, each tenable for five years for boys from a public scholarship, of which the last three years can be passed at the Central Institution. There are also a number of scholarships, premiums, medals, etc., which can be gained by students while at the college. The diploma of associateship is not granted indiscriminately to all the students who pass through the course. Thus we see that since 1887 only 187 diplomas have been granted, while some 154 students, who have either not completed their course or have not reached the requisite standard, have received first or second class certificates. This not only encourages ability and enforces diligence on the part of the students, but completely discountenances the idea that it is only necessary to secure attendance on a three years' course in order to make a competent engineer out of anybody.

Institution of Civil Engineers.—At last Tuesday's meeting Mr. A. E. Hunt, M.I.C.E., read a paper on the manufacture of aluminium by the Pittsburgh Reduction Company at Niagara Falls. Mr. Hunt said the Hall process, which was that adopted by the Pittsburgh Reduction Company, involved the direct electrolysis of the sesqui-oxide, alumina, dissolved in a molten bath of the mixed fluorides of aluminium, calcium, and sodium. One cubic foot of the solvent would serve for an hourly production of one pound of metallic aluminium, the bath used being capable of dissolving one-third of its own weight of alumina. The electrical energy required for extracting this amount of metal was 3,730 watt-hours for the decomposition of the alumina, with a further supply to maintain the bath at the temperature necessary for the molten condition. The fluorides remained unchanged, so that the operation was continuous. The bath was made either from a mixture of fluorspar and cryolite, or from the artificial fluorides; and it might be fused in a separate vessel when starting work, or in the bath by the current itself. Alumina was added at frequent intervals to prevent too great a variation in the resistance of the bath, and the aluminium,

Digitized by Google

as it was produced, was syphoned from beneath the layer of fluoride, where it collected, without interference with the progress of the operations. The oxygen of the alumina was liberated at the carbon anode, which, at the temperature of the bath (980deg. C.) oxidised to carbon monoxide. Outside the bath this was burnt at once to carbon dioxide, and was allowed to escape into the working apartment. The carbon anodes were consumed at nearly the same rate as the aluminium was produced, the amount being about two-thirds of the quantity actually used. The difference of potential theoretically necessary for the separation of the constituents of alumina was about 2·8 volts, but a greater difference was due to the resistance of the bath. The pots employed were of iron with carbon linings, but these could be dispensed with if a high degree of purity was not required. The chief impurities in the finished product were silicon and iron. These were derived from the alumina as well as from the carbon anodes. Aluminium could be produced containing 99¾ per cent. of the pure metal, and was regularly delivered with 99 per cent. The electrolytic baths were joined in series, and all the copper connections were necessarily very heavy on account of the large currents employed.

Acetylene.—M. E. Hospitalier, of the Paris Ecole de Physique et de Chemie, has delivered a lecture on "Calcium Carbide and Acetylene" before the Société International des Electriciens, which is reproduced in full in *L'Industrie Electrique*, and summarised in other French papers. M. Hospitalier notices the difference between the figures of M. Moissan, who, using a current of 350 amperes at 70 volts, works out 40 kilowatt-hours per kilogramme of carbide produced, and those of Mr. Wilson, who, using an industrial plant, obtains the same amount with 1·6 kilowatt-hours, and remarks that the present price charged for the carbide by the Aluminium Industrie Aktien-Gesellschaft at Neuhausen is 400fr. per ton. Either direct or alternating currents can be used to produce the carbide—M. Hospitalier considers the latter preferable—and it is at present manufactured in quantity in America by the Electric Gas Company, in Germany by the Carbid at Berlin, in Switzerland by the Aluminium Aktien-Gesellschaft at Neuhausen, and in France at Froges and Vallorbes. In reference to the properties of the gas, the conclusion is confirmed that it is not in any respect poisonous as was at one time supposed. It is, of course, not respirable, but a mixture in as large a proportion as 40 per cent. appeared to have had no harmful effects on animals breathing it so long as care was taken that a sufficient quantity of oxygen was present. According to Berthelot, however, acetylene is an endothermic gas, and is liable to spontaneous decomposition by a detonator, a question which would have to be considered before it is laid in pipes all over a town like ordinary gas. Although acetylene attacks silver and copper with the formation of explosive compounds, it is without action on iron, lead, and tin, and at ordinary temperatures does not seem to attack sensibly either zinc, brass, or bronze. It follows, therefore, that ordinary gas piping and fittings can be used with acetylene. It is concluded that acetylene produced from calcium carbide will never prove a formidable competitor with gasworks or electric lighting. But the facility with which it can be produced and transported in a liquid state, under pressure, allows of the development of acetylene lighting in country houses, pleasure resorts, and factories situated at a distance from towns. The central electric lighting stations might make up their day load by the manufacture of either calcium carbide or liquefied acetylene for sale beyond the district served by their mains, the result being equivalent to the transport and distribution of electric energy to a distance. It is, however, desirable that the central stations should take up this business without losing time, because M. Hospitalier thinks that there is a considerable probability that calcium carbide may soon be obtained by an exclusively metallurgical process, and possibly as a by-product.

The New Photography.—Mr. Campbell Swinton, assisted by Mr. Stanton, gave a demonstration of photography by means of the Röntgen radiations before the Royal Photographical Society on Tuesday last. The conditions in Hanover-square not being convenient for the use of the Tesla coil apparatus formerly described, Mr. Swinton on this occasion used a Ruhmkorff coil giving a 1½in. spark, and took the usual pictures of metallic objects enclosed in cases, and the human hand, the results being developed on the premises and subsequently exhibited in a lantern. Much interest was displayed in the subject, and the room was inconveniently crowded. With his Tesla coil Mr. Swinton stated that he had succeeded in reducing the exposure for the living hand to 55 seconds, and he is pursuing investigations with a view to bringing the exposure necessary in this kind of work within more reasonable limits. With the Ruhmkorff coil, of course, longer exposures were necessary. One "wrinkle" may be noted, and that is, wherever possible, a series of short exposures should be given instead of a long continuous one, as the glass opposite the cathode becomes very hot under the action of the discharge, and there is great danger of destroying the tube. The succession of short discharges gives time for the tube to cool. At the conclusion of the demonstration there was some discussion, Mr. Gifford remarking that, so far as his experience went, it made no difference to the result whether "rapid" or "ordinary" photographic plates were used. An experiment also described by Mr. Gifford is also interesting from a theoretical point of view. On placing on the sensitised plate pieces of uranium and ordinary glass, Mr. Gifford found that the fluorescing uranium glass appeared more opaque to the new rays than the common glass. The obvious explanation is that a certain amount of the energy of the ray is absorbed to produce the fluorescence, but the experiment ought at once to put an end to the theory, which was started in Germany simultaneously with their discovery, that the action of the rays on the silver salt is indirect, and is due to an (invisible) fluorescence of the glass back. Captain Abney, the new president of the society, was present at the demonstration, but confined his observations to a protest against calling the new process "photography. From this it may be inferred that he does not consider the rays to be of the same character as light rays. On the same principle, objection might be taken to calling the new radiations the "X" rays until their longitudinal vibration is definitely established. Much interest continues to be taken in the subject, both in England and on the Continent. Prof. Wittmann, of the Technical High School, Budapest, is reported to have succeeded in reducing the time of exposure for obtaining well-defined photographs to three minutes in ordinary cases, and to 30 seconds under very favourable conditions. His method is permanently to connect the mercury pump with the vacuum tube. Most applications of the new discovery appear to be surgical, but at Berlin the new radiation photographs have been used to distinguish real from imitation pearls, while the Vienna War Office has ordered a series of experiments to be carried out in the Government gun factory at the Vienna Arsenal for testing the homogeneousness of castings for gun tubes by the use of the new rays. As metals are more opaque than any other substances to these radiations, great success in this direction is hardly to be hoped for.

THE TELEPHONING OF RAILWAYS.

BY J. PIGG.

Considerable attention has at different times been given to the most suitable methods of arrangement for the telephone service of large towns, and spirited debates have frequently taken place respecting the arrangements most likely to produce an efficient service. The writer, however, is not aware that any suggestions have been put forward publicly for the most efficient arrangement of telephone circuits in their adaptation to the special requirements of the railway service.

Of the suitability of the telephone for a very large amount of railway work there can be no question whatever. As a means of communication, it is immeasurably superior to the single-needle telegraph instrument, the predominant type on railways, in that it is quicker, allows greater detail of arrangement, and enables the communicants to come directly together without the intervention of a third party. The use of the telephone for the great variety of detail arrangement required by railway work has advanced of late years more rapidly than that of any other instrument, and the total number in use for railway work must form a respectable proportion of the total number in use for all purposes. Whilst this is undoubtedly the case, it would be unsafe to predict that the use of the telephone in rail way management has reached its maximum. Rather, it would appear as if it was, to use a somewhat well-worn simile, as yet "in its infancy."

To anyone acquainted with the means taken to obtain telephonic communication, and the results accruing, a question naturally arises as to whether the arrangements made are the best that can be devised to obtain the maximum benefit from the circuits erected, and also whether these arrangements are such as to readily co-operate to the best advantage with the extension of the telephone that seems inevitable. Whilst it is true to a very great extent that those who are to work any given telephone circuit are best able to specify the points requiring to be connected, yet it is inevitable that individual arrangements are not likely to be conducive to general effectiveness. It is, perhaps, in consequence of this that the arrangement of railway telephone circuits has been allowed to settle itself to suit purely local requirements, and the maximum capacity of the circuits, as a means of general communication, has up to the present been ignored, to the manifest disadvantage of the general service.

The executive work of a railway is carried on in departments, each of which is under one head, who is assisted by divisional superintendents located at different points in the system, and who, again, are assisted by subordinate officials located at different points in the divisions. In this way almost every department is represented at each of the more important centres of traffic. The work of each department is to a great extent distinct, but, necessarily, the work of each must be carried out in conjunction with that of other departments, whilst much of the work is stereotyped and of a local character only, yet, without going into details, it will be readily seen that the necessity for quick communication between (*a*) officials of the same department in the same locality; (*b*) officials of different departments in the same locality; (*c*) officials of the same department in different localities; (*d*) officials of different departments in different localities, will frequently arise, and much valuable time may be lost for want of adequate means of communication. Hence, in railway work there seems to be four distinct classes of communication to be provided for. Those under the first two heads may, for reference, be termed "local," the third "departmental," and the fourth "inter-departmental," although it is evident that no strict division on these lines can be made, since, in the "local" division, "departmental" and "inter-departmental" working is found.

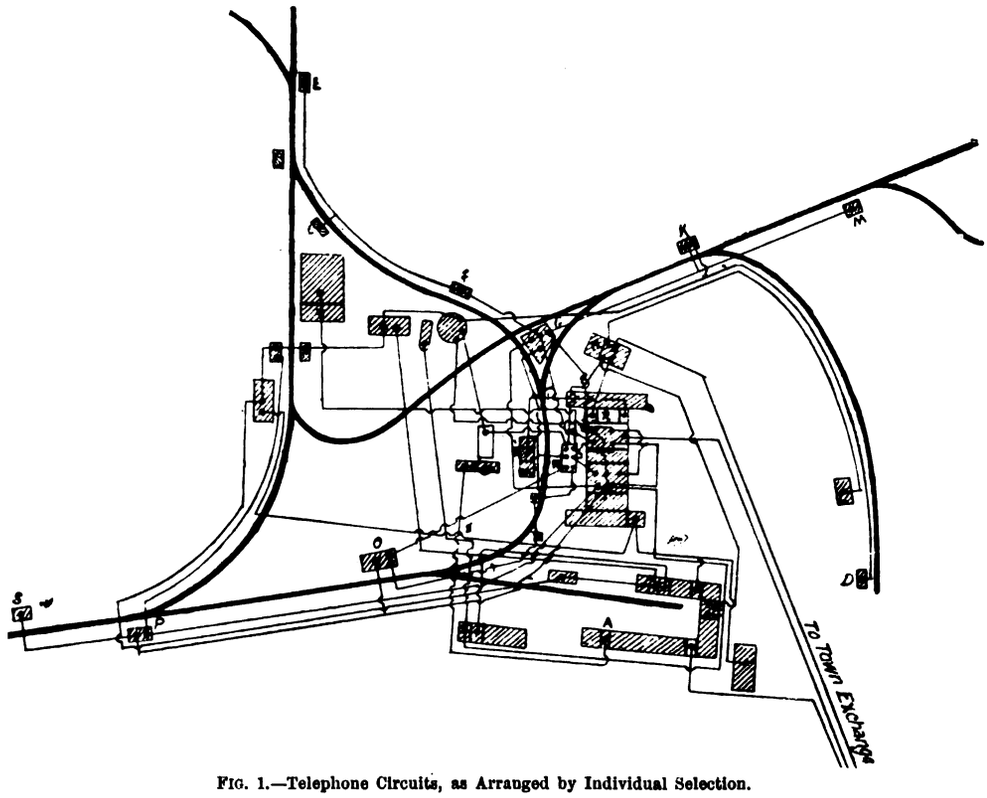

FIG. 1.—Telephone Circuits, as Arranged by Individual Selection.

Considerable progress has already been made in providing telephonic communication of a "local" character in the more important centres of traffic, and in connecting local collecting and distributing areas, but little progress has been made in the other divisions, chiefly owing, no doubt, to the fact that hitherto telephones have been installed on the initiative of some department which felt the need of such accommodation, and the calling points selected to suit the needs of that department alone. The usual course pursued is, when the head of a department recognises the necessity for quicker means of communication, for that department to secure the erection of a circuit calling at such points as its business may require.

If the circuit, when erected, can be used for other purposes than those of the department concerned in its erection, well and good; if not, further arrangements must be made. As a means of facilitating the business of any one department, such an arrangement is eminently practical and businesslike, but since the different circuits so erected do not all centre in one place, and are not arranged for inter-connection, the full value of the circuits in obtaining communication between *all* points

Digitized by Google

provided with telephones is not always obtained even in "local" working.

As an instance of the results accruing from the unchecked individual selection of routes and calling points to suit special work, without co-operation for the greatest possible utility, consider the case shown in the diagram, Fig. 1, which may be taken as an actual example. Within a radius of a little over a mile there are 70 telephones installed on 21 circuits, the number of telephones on a circuit varying from two to nine, and the number in any one room from six to one. The arrangement of the instruments in any room is such that in few cases can conversation be carried on simultaneously by two persons in the same room without great inconvenience and discomfort. Besides this, no circuit is capable of being connected to another circuit, and any interchange of business between officials on different circuits must be done by transmission, where this is possible by the two circuits meeting at some common point. If circuits do not meet, then communication is not possible, though *both* are provided with telephones. An examination of the diagram shows that something very like a special training is needed for an official in one department to discover how he may communicate with another with the least amount of trouble to himself. Add to this the amount of ringing resulting in any room where a number of telephones are fixed, or in any office connected to a circuit with a number of other stations on it, and one ceases to wonder at the unanimity with which the higher officials determine that telephonic communication is more important for their subordinates than for themselves. Perhaps, not the least apparent defect shown by the diagram is seen in the number of points connected with the town exchange.

To the writer it has always appeared that the best method of arranging the telephone circuits of a railway consisted in an adaptation of the exchange system in use for the public service, in which all the "local" circuits at any centre would meet at a common point and be arranged to allow of connections being made between the different circuits as might be necessary. Such circuits need not be, as in the public service, connected to one point and the exchange only, as, in railway work, the need for strict privacy does not exist to the same extent. Such circuits might, as now, consist of three or four stations, communication between which might be carried on independent of the exchange, and attention called by such codes of signals as are now in use. When communication was required between points on different circuits, the connection would be made by the exchange, who would restore the circuits to their usual arrangement when the communication was finished. Such arrangements could not fail to have the most beneficial results on the working of the traffic and the making of detail arrangements, and, besides, would effect a considerable saving in the number of instruments required, and, by reducing the annoyance consequent on the constant ringing of a number of bells in an office, would do much to make the telephone more popular in quarters where it is at present looked upon as an unmitigated nuisance.

If Fig. 1 is contrasted with Fig. 2, which is the telephone system of Fig. 1 as it could be arranged and worked on the exchange system, due regard having been paid to circuits required for extra special purposes, a marked difference will be noted. The total number of instruments required is now only 47, or nearly 33 per cent. less than with the existing arrangement, whilst, in striking contrast to the arrangement shown in Fig. 1, every official provided with a telephone is capable of being put in direct communication with every other official similarly provided, and each telephone on the railway company's exchange is capable of being connected to the town exchange, although only one connection is needed instead of three as before.

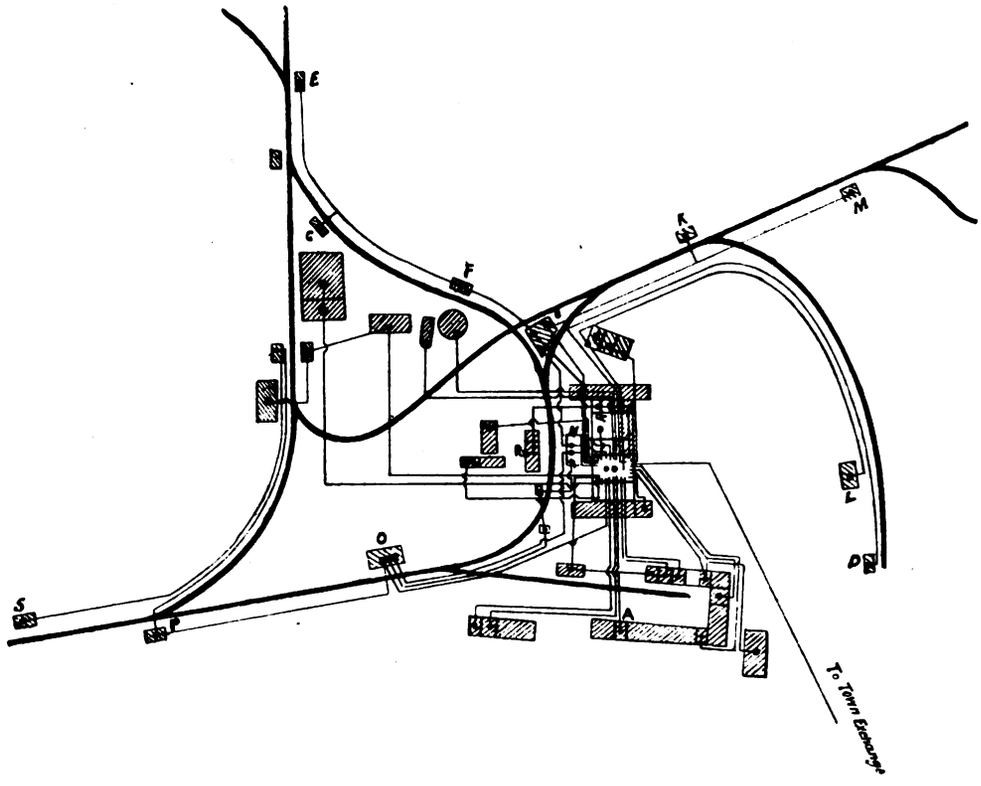

FIG. 2.—Telephone Circuits, Arranged for Complete Inter-communication.

A further application of the exchange system to "departmental" and "inter-departmental" working would be effected by the erection of trunk wires between the headquarters of the divisional superintendents. Each trunk wire would terminate in the local exchange at each end, and would be available for connecting together any of the circuits at those places. By judicious selection of the routes of the trunk wires all the divisions might, as shown for a particular case by Fig. 3, be brought into telephonic connection without much trouble or expense. By these arrangements railway managers would be provided with means of communication such as have never yet been available, either by their telegraph or telephone systems, and the organisation of the latter on some such basis as that outlined would do much to relieve the former from its present congested condition.

All this is, of course, very elementary and common knowledge, and the managers of telephone systems are entitled to smile complacently on reading of the direction in which the railway telephone service is trending, yet the

Digitized by Google

fact that such a state of things exists is sufficient apology for calling attention to it. Every year of delay will add to the intricacy of the service and increase the expense of reorganisation when the present system has become intolerable. Such an arrangement, or rearrangement, as that suggested will never be obtained under the existing method of procedure, since the officials of the different departments are naturally most interested in their own business, and not fully cognisant with the requirements of or what is being done by their colleagues in other departments. It is therefore necessary that the work of organisation should be undertaken by some independent official who could consult with all parties as to their requirements, and who, having knowledge of all that was being done in that direction, would be able to concentrate the whole to the best advantage. Such official would naturally be the company's electrical engineer, since he is concerned in the erection of all circuits, and he alone has knowledge of all the arrangements being made. From his advantageous position the electrical engineer would be able to arrange the circuits to a maximum of efficiency at a minimum of cost, and, as will be seen from the foregoing, it is very desirable that he should have a freer hand in making circuit arrangements.

The great bugbear of railway telephony is caused by the complex phenomena which, whilst comprising the action of neighbouring circuits, earth currents, magnetic changes, atmospheric changes, and the distortion of the earth's field

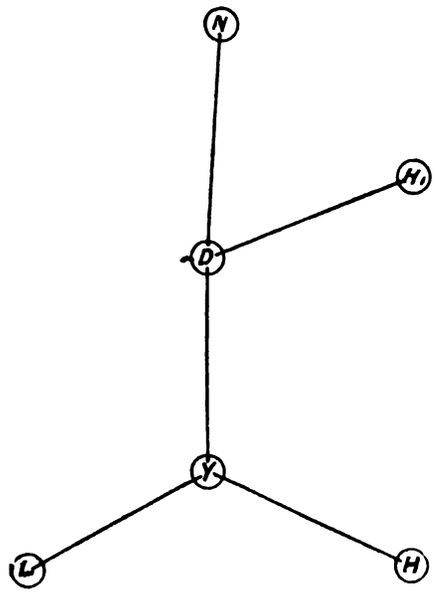

FIG. 3.—Arrangement of Trunk Wires.

by rapidly-moving large masses of iron at varying distances in the vicinity of the wires, are all summed up in the general term "inductive disturbance." This disturbance, whilst at all times annoying, becomes on some lines, and at certain times of the day, so great as to almost prevent the use of the circuit. In the early days of telephony, railway officials were so delighted with the ease and speed of working that a comparatively small defect such as this was overlooked or condoned in consideration of the numerous other advantages the instrument possessed over those to which they had been previously accustomed. With greater familiarity and more extended working the defect made itself more apparent, and the complaints on this head are now frequent and plain.

Whilst much may be done by intelligent adjustment of the instruments, yet the only remedy worth the name consists in doubling the circuits and twisting the wires. Railway electrical engineers have, with some exceptions, been somewhat tardy in recognising the need for these special arrangements, and some are said to look with grave displeasure on any proposal to double any troublesome circuit, to say nothing about twisting the wires. Whether this disinclination arises from a desire to preserve the geometrical symmetry of the wires on their lines, known as the "regulation," or to some other reason, it is nevertheless certain that they will in the near future be obliged to bring themselves into alignment with their more advanced *confrères* on this matter.

CITY AND GUILDS OF LONDON INSTITUTE.

LECTURE XXIV.

(Specially Contributed.)

Hot-Wire Voltmeters.—A pretty experiment that is frequently shown is to take a conductor of wire made of alternate pieces of copper and platinum. When the circuit is completed the platinum sections of the conductor soon rise to a red heat, thus giving visible evidence of the heat-producing properties of an electric current. The platinum sections, if of the same length and sectional area as the copper sections, have a much higher resistance than the copper sections, and it seems as if this heat is generated and radiated at the sections of high resistance. This is not so: it is generated and radiated at all parts of the conductor, but the temperature of the part of higher resistance increases much more rapidly than the temperature of the part of lower resistance. Suppose, instead of alternate sections of the same length, we took alternate sections of the same resistance, then the same amount of heat would be generated in each section; but we shall not get the same visible results, for the surface area of the mass of copper which has the same resistance as a section of platinum is very large compared with the surface area of the platinum. The larger the surface area the larger the area for radiation and the less the rise in temperature. The temperature rises till the heat radiated equals the amount of heat generated. We have found by experiment that a current of an ampere through an ohm resistance produces 0·24 heat unit per second—that is, each ohm of wire will heat 0·24 gramme of water through 1deg. C. per second, which is about 0·13̇ of a gramme through 1deg. F. per second. If the current is doubled the heat generated is *four* times as great, for the heat generated is proportional to the square of the current, hence

1 ampere through 1 ohm gives 0·24 heat unit per second;
2 amperes through 1 ohm give 4 × 0·24 = ·96 heat units per second;
3 amperes through 1 ohm give 9 × 0·24 = 2·16 heat units per second.

The heat generated is directly proportional to the resistance, hence doubling the resistance means doubling the heat generated.

1 ampere through 1 ohm gives 0·24 heat unit per second;
2 amperes through 1 ohm give 4 × 0·24 = ·96 heat units per second;
2 amperes through 2 ohms give 2 × 4 × 0·24 = 1·92 units per second.

Hence we may use the formula,

$$\text{Heat generated} = 0{\cdot}24 \times C^2 \times R \times t \text{ heat units,}$$

where C = current in amperes;
R = resistance in ohms;
t = time in seconds.

The Calorimeter.—The apparatus used for determining the heat generated in a wire carrying a current is

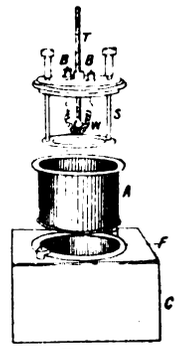

FIG. 1.

called a calorimeter. Fig. 1 shows the apparatus. Many precautions, of course, and great care have to be taken to obtain accuracy. The wire, W, is placed in the vessel, A, containing a badly-conducting liquid, such as refined coal-oil, or alcohol, or water. The current is conducted to W

Digitized by Google

by the binding screws, B B. The voltage between B B is measured, as is the current, and, knowing these, the resistance of W is easily found. T is a thermometer to show the rise in temperature, and S is a stirrer to mix the liquid and obtain uniform temperature. The vessel, C, containing the liquid is placed in a felt wrapper, F, and this again in a box filled with loosely-packed sawdust or similar non-conducting material to prevent loss by radiation. Suppose vessel A and stirrer, S, of brass, and to weigh 200 grammes. It requires 0·093 heat unit to heat one gramme brass 1deg. C., so to raise vessel and stirrer 1deg. C. requires $0{\cdot}093 \times 200 = 18{\cdot}6$ heat-units. If A contains x grammes of water, and temperature rises T degrees in t seconds, then x T heat units have been given to the water, and the total heat generated is $18{\cdot}6\,T + x\,T$ units.

If the formula given above is correct, then

$$0{\cdot}24\,C^2 \times R \times t = 18{\cdot}6\,T + x\,T.$$

The heat unit above taken may be called the gramme-degree, and it takes 424·5 of these to make a unit = a gramme-metre—that is, one gramme lifted the height of a metre, which is a work unit often used instead of a foot-pound. We have seen that 33,000 foot-pounds per minute, or 550 foot-pounds per second, are equivalent to 1 h.p., and 76 kilogramme-metres per second are also equal to a horse-power; hence, whether we use the gramme-degree Centigrade heat unit, or the pound-degree Centigrade, or Fahrenheit, we can get the horse-power. If our unit is the heat required to raise 1lb. of water from 0deg. C. to 1deg. C., then the constant 0·24 given above must be changed to 0·0315, and the formula written

$$\text{Heat generated} = 0{\cdot}0315\,C^2 \times R \times t \text{ heat units.}$$

According to Joule the mechanical equivalent of heat is, using C. degrees, 1,390 (Prof. Ayrton in order to get round numbers, I suppose, uses 1,400), so that

$$W \text{ (foot-pounds)} = 1{,}390 \times 0{\cdot}0315\,C^2 \times R \times t;$$
$$= 43{\cdot}78\,C^2\,R\,t \text{ (say, } 43{\cdot}8\ C^2\,R\,t).$$

But

$$C = C\,\frac{E}{R};$$

so that we can write $= 43{\cdot}78\,C\,E\,t$ (say, $43{\cdot}8\,C\,E\,t$).

(If 1,400 is used instead of 1,390 then 43·8 will become 44·25, which is more incorrect, because 1,390 is nearer the truer number, 1,389·6, than is 1,400, and there is no use to be more incorrect than the nearest whole number.)

Example.—Suppose a wire having a resistance of one ohm carries a current of 10 amperes, what is the loss in horse-power?

Heat units generated and lost (radiated) per second $= 40{\cdot}2 \times 10^2 \times 1 = 24$.

Work units (gramme-metres) per second $= 24 \times 424{\cdot}55 = 10{,}189{\cdot}2$.

10,189·29 gramme-metres = 10·1892 kilogramme-metres.

76 kilogramme-metres per second = 1 h.p.

$$\therefore \frac{10{\cdot}1892}{76} = 0{\cdot}134 \text{ h.p.};$$

that is, 0·134 h.p. is lost by the dissipation of energy in such a wire.

If the current was 30 amperes instead of 10 amperes, the loss would be not *three* but *nine* times as great; because the loss, or the heat generated, varies as the square of the current.

Example.—If four amperes flow through a resistance of 4½ ohms for 20 minutes, how many foot-pounds of work are done?—(Ayrton.)

Prof. Ayrton gives the formula,

$$44{\cdot}25 \times C^2 R;$$

and the answer, 63,720.

According to the above the formula should be

$$43{\cdot}8\,C^2 R;$$

and the answer,

$$43{\cdot}8 \times 4^2 \times 4\tfrac{1}{2} \times 20 = 63{,}072;$$

the difference being caused solely and wholly by the approximation to 1,389·6 being taken in the first case as 1,400, and in the second, and I think the more correct, as 1,390. I call attention to this serious state of things, and especially from a student's point of view. The laxity of authors in choosing approximations should be regulated, and upon no account should a student lose marks because he uses another constant than that favoured by an examiner.

Expansion by Heat—All bodies expand when heated. It has been seen that a current passing through a wire heats that wire. Therefore the wire will expand. We need only trouble here about the linear expansion—that is, the expansion in length, or the elongation due to the heat. It is found that if a bar of iron, for example, be raised in temperature, its elongation per degree of temperature is very nearly uniform at all ordinary temperatures. Thus, if we take a bar of iron a foot long and raise its temperature 1deg. C., and carefully measure the elongation (call it x), the length of the bar at the higher temperature will be 1ft. $+ x$ the elongation. If we raise the bar two degrees its length will be 1ft. $+ 2x$; if we raise it three degrees, its length will be 1ft. $+ 3x$, and so on, if the temperature is raised n degrees the increase of length is nx.

The number representing the extension in length is called the coefficient of expansion. Thus if the coefficient of expansion of iron is 0·000012, then a bar of iron

1 foot in length raised 1deg. C becomes 1·000012ft. in length;

1 yard in length raised 1deg. C becomes 1·000012 yards in length;

1 mile in length raised 1deg. C becomes 1·000012 miles in length.

I need not repeat this at length, but one more example must suffice. If the bar of iron is raised 20deg. C. in temperature, then

1 foot in length raised 20deg. C. becomes

$$1 + 20\ (\cdot000012) \text{ feet in length.}$$
$$= 1{\cdot}000240 \text{ feet in length.}$$

Coefficients of Expansion for 1deg. C. (Kohlrausch).

Aluminium ...	0·000023	Brass	0·000019
Lead.....	0·000029	German silver ...	0·000018
Iron	0·000012	Platinum	0·000009
Glass	0·0000085	Platinum-iridium .	0·000009
Gold.....	0·000015	Silver	0·000019
Copper.....	0·000017	Zinc.....	0·000029
Vulcanite.....	0·00008	Tin	0·000023

Before leaving this table, let me just direct attention to the similarity between the coefficients for glass, platinum, and platinum-iridium, as, practically, advantage has been taken of this fact in the manufacture of incandescent lamps.

So far as instruments are concerned, it is easily seen that the elongation of a wire due to heat generated varies as the square of the current, and so can be used as a measure of pressure—that is, can be utilised as a voltmeter. No satisfactory ammeter has been made upon this principle. These instruments are used both for direct and alternate current circuits.

Cardew's Voltmeter.—Major Cardew was the first to take advantage of the heating properties of the current in the design of a voltmeter. If a wire, W W (Fig. 2), be

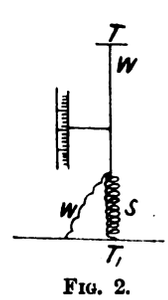

Fig. 2.

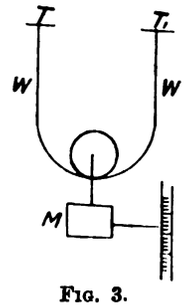

Fig. 3.

fixed as shown between the terminals, T T_1, fastened, say, to T_1 through a spring, S, and a current be sent through it, the spring will take up the elongation which will be shown by the pointer, P, on the scale. Another way of getting the elongation due to rise in temperature shown would be by an arrangement as in Fig. 3, where T T_1 are the terminals, W W the wire. The wire carries the weight, M, which, again, carries a pointer, P. Any extension of the wire is shown by the pointer on the scale.

Digitized by Google

Do not forget the wire rises in temperature only so long as the radiation is less than the generation. The wire will not elongate when the radiation and generation are equal; but then its length is constant. Fig. 4 shows a form of Cardew's voltmeter. In it some 13ft. of platinum-silver wire, 0·0025in. in diameter, is stretched between the two terminals. Follow the course of the wire. Commencing at the screw terminal T, it

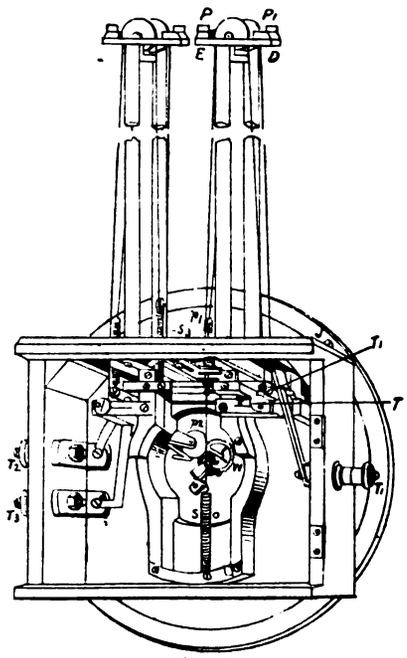

FIG. 4.

goes over pulley P, down under p, back over P_1, and down to terminal T_1. The pulley p is connected by a fine flexible thread, which goes once round the pulley p_2 to the spring, S. Thus the wire is kept stretched by the pull of the spring, S, and if it lengthens, the thread around the pulley p_2 turns the pulley which carries on its axle another toothed wheel, W, which works a pinion carrying a pointer. The terminals T T_1 are connected to outside terminals, T_2 T_3. The action of the current is to raise the temperature of the wire, which lengthens. The increase in length is taken up by the spring, which action turns the wheel p_2, the toothed wheel, W, and thus moves pinion and pointer. The movement of the pointer is shown on a scale on the face of the instrument. In the more recent instruments a duplicate wire is placed similarly to the one just described, and this second wire is so arranged that it can be placed in series with the first, so doubling the range of the instrument. The dial face in the instrument with a duplicate wire is graduated for two sets of observations—the one when one wire is used, the other when both are used in series. The fine wires are protected by tubes, and the whole apparatus encased to prevent errors from outside thermal influences. The scale divisions are made from experiment. It is hardly necessary to point out that it is the extension of one half of the wire only that influences the deflection of the pointer. It is not necessary to measure the extension of the whole wire, which would simply be twice or four times greater as one or both sets of wire were used. The extra length of wire used is to obtain resistance; this will be understood by referring back to what has been said about the resistance of ammeters and voltmeters.

The Acme Voltmeter.—This is another form of hot-wire instrument made in America. I am indebted to Mr. Wiener for the description. In Fig. 5, B_1 shows a fixed support to the wire, A, which at the other end goes to the phosphor-bronze spring, C. The wire, A, is 0·0012in. diameter and 6·5in. long. At D, midway between B_1 and C, it is connected to a phosphor-bronze strip rolled flat from a wire 0·0015in. diameter, which passes round the index shaft, E, engaging with the two pins, F F, attached to the collar, G, and on to the spring, S. The strip, D, is connected to A through a piece of glass as an insulator, which carries a platinum hook. It is easily seen that under a current A extends, and is bent by the pull of spring, S, through D. The pull is shown by the index. The two wires A_1 A_1 are the same length as A, but are not acted upon by the current. They serve an important function, however, in restraining C from taking up the expansion of A due to current, and allowing it to take up expansion from any other cause. In other words, they allow C to follow external changes of temperature, and thus com-

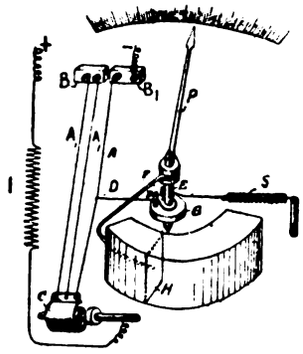

FIG. 5.

pensate for any deviation in the zero position of the pointer for varying temperatures. To make the instrument dead-beat, a vane, H, acting in an air-chamber, is attached to the pointer shaft.

Other instruments of this kind are made, but enough have been described to show how they work and the principle under under which they can be used as voltmeters.

THE STANDARDS OF LIGHT.*

BY W. J. DIBDIN, F.I.C., F.C.S., ETC.

(Concluded from page 159.)

The important point of uniformity was then tested. For this purpose Mr. Sugg was requested to make two dozen of the burners, which were distributed amongst members of the committee, who found that they all gave results practically identical with one another, showing that no difficulty will be experienced in producing a number of these burners suited to serve as standards.

In order to ascertain whether the burner first submitted was capable of modification so as to simplify its construction without affecting the constancy of the light emitted by the flame when at various heights, a number of experiments were made, with the result that the committee arrived at the conclusion that the 10-candle pentane-Argand would, with a slight modification, be in every respect a trustworthy standard when supplied with atmospheric air carrying the vapour of pentane supplied by the carburetter provided. The modification alluded to consisted in the substitution of a rectilinear for a curvilinear solid cone for greater convenience and certainty in measurement, and defining the distance at which it is to be fixed below the centre opening of the burner.

The following description of the 10-candle pentane-Argand air-gas standard, as recommended by the committee for use in gas testing, is given in Section IX. of the appendix to the report of the committee:

Description of Dibdin's 10 Candle Pentane-Argand Air Gas Standard, as recommended by the Committee for use in Gas Testing.—The apparatus used in producing this standard of light consists of two separate portions—viz., the burner and the carburetter. The burner is a specially constructed tri-current Argand burner, the annular steatite ring being perforated with 42 holes, each hole being 0·71 millimetre in diameter. The three air currents are: (1) the central current rising inside the steatite to the inner portion of the flame; (2) a current rising outside the steatite, and caused to impinge upon the flame by an inner metal perforated and incurved cone, the top of which is level with the top of the steatite; (3) an outer current rising on the outside of the above cone, and between that cone and the glass chimney. The inner perforated cone is punctured with 10 apertures 0·25in. in diameter, which are provided for the purpose of equalising the two outer currents of air as may be required to suit the height of the flame. The glass chimney is carried in the groove provided on the outer cone, which answers the purpose of a gallery, the dimensions of the chimney being 6in. high and 1½in. inside diameter. The top of the flame should be maintained as nearly as possible at 3in. above the steatite, this point being indicated by the wires crossing the blue glass screens carried on each side of the burner on the metal supports. The flame is steadied by the small air-directing cone situated centrally beneath the steatite, the apex being 0·03in. below the metal support carrying the steatite. On the side of

* Paper read before the Society of Arts,

Digitized by Google

the burner to be presented to the photometer disc a metal screen 8½in. in height is placed and screwed securely to the base-plate. The middle portion of this screen is cut away, so as to leave above the top of the steatite burner an opening 2·15in. in height and 1·4in. in width, the lower portion of this opening being exactly level with the top of the steatite. The light emitted horizontally through this opening by the flame produced by the combustion of the gaseous mixture of atmospheric air and pentane formed in the carburetter described below is used as the standard of light. It is equal to the light emitted by 10 parliamentary sperm candles. The lower portion of the screen has an opening, 1in. wide by 2·3in. in height, to allow free access of air to the under portion of the burner. The various dimensions and arrangements of the parts are more particularly described in the following table of measurements. The position of the burner in relation to the photometer disc is to be fixed by the burner fitting gastight into a faced joint attached to the photometer at the required point; and the burner is to be set at such a height that the centre of the illuminated disc and the bottom edge of the cut-off shall be in the same horizontal plane. The length of the connection between the burner and the carburetter may be varied, but should not be more than 5ft. The centre of the flame is to be immediately over the terminal point of the photometer bar. The carburetter for the 10-candle pentane-Argand consists of a circular vessel constructed of tinned plate:

Diameter ..... 203·2mm. = 8in.
Depth..... 50·8mm. = 2in.

Having a spiral division 25·4mm. = 1in. in width. This division is made by soldering in a spiral strip of metal 4ft. 6in. in length and 2in. wide, gastight, to the underside of the top of the carburetter, so that when the top is fixed on the bottom of the strip comes close to the bottom of the vessel and is sealed by the pentane, so that the air has to pass over pentane for a distance of about 4ft. 6in., and becomes thoroughly saturated. At the end of the spiral division, near the side of the carburetter, a bird fountain is fixed for charging the carburetter and keeping it charged at a constant level with liquid pentane. The lower end of the inlet fountain tube is closed, and rests upon the bottom of the tank. Through the side of the tube, which is $\frac{4}{10}$ths of an inch (10·1mm.) in diameter, 16 holes 1mm. in diameter are bored close to the bottom, and through these the pentane enters the carburetter. At one side of the inlet tube, and 1in. from the lower end, a small tube 33mm. in diameter and 20mm. in length is connected thereto and turned upwards. The fountain inlet tube is carried up through the top of the carburetter, and continued in the form of a bulb having a capacity of about 200 cubic centimetres. Stop-cocks are provided at the top and bottom of the bulb for convenience in filling with pentane, and the portion above the upper stop-cock is opened out in a funnel shape for the same purpose. When the carburetter is being charged, the gas must be extinguished to avoid the risk of the vapour firing and causing an explosion. The inlet for gas or air is at the side of the carburetter, and at one terminal of the spiral division, the outlet being placed in the centre of the vessel, so that the air or gas may travel over the liquid pentane throughout the whole length of the spiral division, and thus become fully charged with the volatile vapour of the pentane. When using this standard, the pentane must be visible in the fountain bulb.

Measurements of Mr. Dibdin's 10-Candle Pentane-Argand Burner.

Number of holes	42	
	mm.	in.
Diameter of holes	0·71	= 0·028
Inside diameter of steatite	9·90	= 0·390
Outside diameter of steatite.....	19·05	= 0·750
Diameter of inside of metal cone at top	23·62	= 0·930
Chimney length.....	152·4	= 6·000
Chimney inside diameter.....	38·1	= 1·500
Height of cut-off	54·61	= 2·150

The centre of the flame to be immediately over the terminal of the photometer bar.

This form of standard has been modified so as to yield a light of one or two candles, as desired; also 16 candles. In the case of the burner yielding one or two candles, as required, the flame may be used in two ways, either with or without the screen, or "cut-off." If without the screen it is equal to 1·0 candle when the flame is 1·25in. in height, and to 2·0 candles when 2·30in. in height. In either of these cases, of course, there is no "allowable variation" in the height of the flame. When the screen is employed, however, the value of one candle is obtained, when the screen is set 0·92in. above the burner, and the height of the flame is kept within from 1·5in. to 2·0in., thus having an allowable variation in height of ½in. The value of 2·0 candles is obtained when the screen is set 1·64in. above the burner, and the height of the flame is kept within from 3in. to 4½in., thus having an allowable variation of 1½in.; the chimney employed with this standard being 4·5in. by 1·25in. inside measure.

The term "allowable variation" is used merely to indicate the tolerance of the burner in unskilful hands, so that if by a mistake or error of judgment the height of the flame is not fixed to the mean point, but is anywhere within the limits of the allowable variation, the results will not, for all practical purposes, be vitiated. In exact work, however, it is always to be understood that the height of the flame should be that indicated in each case as the mean of the "allowable variation"—viz., with the one-candle screened flame, 1·75in.—and with the two-candle screened flame, 3·75in. In like manner, the allowable variation of the 10-candle pentane-Argand is from 2·5in. to 5in., and that of the 16-candle pentane-Argand from 3·5in. to 7in.

The pentane employed to produce the air-gas used in Mr. Harcourt's one-candle standard, and in the carburetter of the 10-candle pentane-Argand, was obtained by purifying light petroleum by the successive action of sulphuric acid and soda solution, and then distilling at 60deg. C., at 55deg. C., and twice at 50deg. C. It was, however, considered important to obtain samples of pure isopentane from other sources in order to ascertain if the air-gas prepared from them would give the same amount of illumination as with the normal pentane. For this purpose a sample of so-called pure isopentane was obtained from Berlin, but on examination proved to be unsatisfactory. Accordingly, Prof. T. E. Thorpe was requested to have a sample of pure isopentane prepared. This task he kindly undertook, and with the assistance of Mr. A. Greeves three specimens were made and submitted to the committee. The method used was, shortly, as follows: The mixture of active and inactive amyl alcohols, obtained by the purification of fusel oil boiling from 120deg. to 132deg. C. under a pressure of 760mm., was converted into a mixture of iodides, which was then reduced to isopentane by means of the zinc-copper couple. Three samples were thus prepared from German, Scotch, and Irish fusel oils, all the conditions being strictly comparable. These were handed to the committee and experimented upon both with the one-candle pentane flame and the 10-candle pentane-Argand. In the case of the former it was found that rather more light was yielded by the isopentane than by the normal pentane obtained from petroleum. In the case of the 10-candle pentane-Argand, however, identical results were obtained with either sample, this, doubtless, being due to the remarkable compensating action of the flame yielded by that burner in a manner similar to the compensating action which takes place when air is replaced with coal-gas as the medium for driving forward the vapour of the liquid pentane in the carburetter. This result points to the conclusion that the pentane-Argand enables either of these combustible materials to be employed without any practical difference in the amount of light passing under the screen and employed as a standard; hence, should there be at any future time a suspicion that commercial pentane has altered in respect of its illuminating value, it can always be standardised by an appeal to the light of the pentane-Argand burner fed with air carburetted with pure isopentane.

An important question having been raised by Mr. John Methven as to the effect of the humidity of the atmosphere upon the amount of light emitted by a luminous flame, the committee gave the matter very careful consideration, and a prolonged series of experiments was undertaken by the secretary, Prof. Vivian B. Lewes, F.I.C., to elucidate the matter.

Mr. Methven had found that when the temperature was practically constant, candles gave per 120 grains of sperm consumed a light equal to 1·104 as compared with a constant source of light (Methven screen), and that this was increased to 1·196 when the air in which the candles were burning was dried. This difference in the light value he considered to be due entirely to the removal of the moisture, as the temperature remained the same. He also found that when air saturated with moisture at increasing temperatures is supplied to a flame, the light value rapidly diminished, so that between the temperatures of 50deg. F. and 75deg. F. a diminution of 10 per cent. takes place in the light emitted by an Argand flame burning five cubic feet of gas per hour, while with a flat flame a reduction of 12·2 per cent. took place, and with a gas flame from a two-candle burner a loss of 13 per cent. was found within the same range of temperature.

Mr. Methven ascribed these differences to the different power of the flames to battle with the aqueous vapour. The result of the committee's experiments was that, although by abnormally saturating or drying the air supplied to a flame, variations as great as those obtained by Mr. Methven undoubtedly occur, yet that in a well-ventilated testing-room, with the temperature kept within a narrow range, no such great differences are to be found. These conclusions were also supported by the experience of Mr. Vernon Harcourt, Mr. Greville Williams, and Mr. W. C. Young; and it did not therefore appear to be necessary to take this otherwise important point into consideration in connection with the enquiry, especially as the value of the standard recommended was so close to that of the light to be tested, and thus any variation in the one would be balanced by that in the other.

In view of the definite results obtained the recommendation of the committee to the effect that the gas referees should be authorised, should they at any time see fit, to approve and certify for gas-testing any other flame based upon the 10-candle pentane-Argand would appear to be unnecessary, as opening the door to alterations from time to time, and thus again reopening the question which all desire so earnestly to see settled. The provision, however, that no alteration should be so made without the sanction of the Board of Trade and the gas companies would provide a safeguard against any interference with the standard on trivial grounds, is well advised. But undoubtedly the other parties to the contract—viz., the controlling authorities, as representatives of the public—should be equally repre-

Digitized by Google

sented with the gas companies, and doubtless this will be provided for in any Act legalising the present proposed alteration. In that case no objection can be raised to the clause, and the advantage gained would be that in case the advance of knowledge should place at the hands of the operator a still more convenient and reliable process, it would not be necessary to incur the delay and expense of another Act of Parliament, the needful authority for the change being merely a notification of the gas referees to that effect.

In this connection I have much pleasure in calling attention to a form of 10-candle pentane burner proposed by Mr. A. Vernon Harcourt, in which the pentane is burnt after the manner of petroleum, in that the vapour is raised to the metal burner by the agency of a cotton wick, the air supply being admitted to the burner from outside as in the case of the P_2 one-candle lamp of that gentleman. With reference to this suggestion, I am unable to speak in the absence of experience with it in practice; but whether in regard to this or any other method which may be proposed hereafter I have only one wish, and that is that the public should have the benefit of the best available means of producing a standard light, and that whenever a better system than the pentane-Argand is found I shall be one of the first to advocate its use. Sixteen years ago I advocated the adoption of the Keats lamp; seven years later I found that the Harcourt one-candle standard gave better results in the hands of various operators than the apparently more delicate Keats system, and I used my best endeavours to obtain its adoption. Now that it is universally admitted that the pentane-Argand which I have since elaborated so as to provide a good working instrument as well as an accurate standard is by far the most desirable form, if not the only practical one acceptable to all parties, I desire that its use shall be legalised; and that, in order that there shall be no "dog-in-the-manger" policy, the machinery should be provided by means of which any improvement of the present best-known method may be legalised without the cumbrous "Act of Parliament" having to be called into requisition.

To many it may seem to be a matter of regret that the question of the method of burning the gas to be tested should have been imported into the question, as tending to complicate the simple question of the standard of light, especially as it is a question of how far any benefit would arise to the public generally by such a change—the possibility, indeed, being that it would tend solely in favour of the sellers of gas rather than the users. As, however, the gas companies were urgent in representing the desirability of this point, as appears from the notes of the interview which the committee had with the representatives of the Incorporated Institution of Gas Engineers and the Incorporated Gas Institute, such an alteration as proposed—viz., "That the requirement that the gas shall actually be consumed at the rate of five cubic feet of gas be rescinded, so as to allow the gas referees to sanction a mode of testing in which the gas shall be burned at whatever rate is found requisite, in order that it may give a light equal to that of the prescribed number of candles;" or, in the words of the gas representatives, "that the rate of the consumption of gas to be tested be adjusted as nearly as practicable to the maximum efficiency of the various standard burners"—does in effect upset the existing bargain between the gas companies and the public, as repeatedly sanctioned by Parliament. The simple substitution of a reliable for an unreliable standard is a question which does not affect the existing contract, whereas the committee afford no evidence of an experimental character to warrant the further change thus proposed.

Having thus fully considered the most recent work in this connection in England, it will not be without interest to discuss the most modern work on the Continent on the subject. This is contained in the report of the Dutch Gas Association on photometry which was issued in 1894. The report is an able and exhaustive account of a special enquiry upon the whole question of photometry as applied to the estimation of the illuminating power of coal-gas, and especially so with regard to the standard of light. After a careful *résumé* of the work hitherto accomplished in this direction, the committee of the association arrived at the conclusion that none of the existing proposals met all the requirements of an ideal standard, and, consequently, proceeded to devise a method which they considered fully answered all purposes. It is to be noted that their report contains no reference to the pentane-Argand, which does not appear to have attracted their attention, although it has now been before the public for nearly 10 years, but in a less prominent form than it has now assumed in consequence of the work of the Board of Trade committee.

The lamp designed by the Dutch Association is based upon the one-candle pentane lamp, known as the P_2 lamp, of Mr. Vernon Harcourt, in which that gentleman employed the device, first introduced by myself, of cutting off the top portion of the flame by means of a screen, in a similar manner to that employed in the pentane-Argand. Instead of using pentane for the fuel a mixture of 9 of benzol to 100 of sulphuric ether is preferred. Experiments showed that between 7·7 and 11·2 parts of benzol the effective variation of the light is only 1 per cent.; whilst between 8·5 and 10·2 parts it is only 0·1 per cent., and the light is therefore practically constant when the benzol varies between 8·5 and 10·2 parts to 100 of ether. This mixture, made up with ether of specific gravity of 0·7215 and benzol of specific gravity of 0·886, had a specific gravity of 0·7335, all at 15deg. C.; but it was found that after 33 per cent. of the contents of the reservoir had been burned away, the residue retained exactly the original specific gravity of 0·7335. The mixture had, therefore, evaporated as a whole, and could thus be used as a standard fuel for the lamp. Various experiments with pure and impure ether showed that no difficulty could be experienced in daily work from casual impurities, although pure ether is recommended for use in standard instruments. Using this arrangement as a standard the Dutch Committee found that the amyl-acetate lamp = 0·9213 candle, = 0·8333 German candle; the English candle = 1·0854 amyl-acetate lamp, = 0·9045 German candle; German candle = 1·2 amyl-acetate lamp, = 1·1053 English candle. Three specimens of the carcel lamp were tested with the average result that the carcel is equal to 9·631 English candles, which agrees with the Kirkham and Suggs's experiments in 1869, who found the carcel to equal 9·6 candles; and the tests made by myself, in 1885, when comparing it with the Keats lamp, the result being 9·61. A series of tests against the one-candle pentane air-gas flame made at the same time as those with Keats's lamp gave a mean result of 9·35, which, however, corrected for the method of setting the pentane then employed, as above described, by the factor 2·59 per cent., a correction only discovered seven years later, gives a result equal to 9·63. These remarkable coincidences of the results of different observers at widely different periods, and by equally widely different methods, are not a little satisfactory in many respects, and serve to show the nature of the work which can be accomplished when a sufficiently large number of experiments are made to eliminate the accidental errors due to isolated tests.

From the above *résumé* of the position of the question of providing a substitute, acceptable to all parties, for the present legal candle, it will be seen that all that remains to be done is for Parliament to sanction the proposed change; and by thus legalising the pentane-Argand bring to a conclusion a question which has gradually ripened until it would seem as if the last word had been said; and there is nothing to delay the closing scene by parliamentary action. Sufficient time has elapsed since the publication of the report of the committee for thorough trial of the new standard, and there should be now no question as to the result. It is to be hoped that the discussion of the facts which I have ventured to place before the society will be such as to strengthen the hands of the Board of Trade when dealing with the matter during the ensuing session of Parliament.

DISCUSSION.

Mr. A. Vernon Harcourt, F R S, said he could add but very little to what Mr. Dibdin had said; for if he had been asked to give a paper on this subject, having in his recollection the work of the committee on which both Mr. Dibdin and himself had been engaged for two years, it would have borne a great likeness to the one they had heard; and there were only one or two points on which he should wish to make any addition. Perhaps it would have been wiser if the committee had limited itself to the matters referred to it, and only made a recommendation as to the standard of light; but it did make a recommendation as to a nearly related subject, which affected the actual use of the standard in testing the illuminating power of gas. The recommendation was that, instead of the gas being tested at the uniform rate of five cubic feet per hour at the standard burner which had been prescribed for testing purposes, it should be burned at such a rate as would give from that burner a uniform light of 16 candles. Working in that way the test might still be regarded as giving the illuminating power of the gas by assuming that the quantity of gas required to give a certain amount of light varied inversely with the quality of the gas. That was substantially true; and if the recommendation were adopted there would be the advantage that the quality of the gas would be judged precisely from the consumers' point of view. Such a mode of testing would correspond more nearly than the present, with the effect on the consumer of a variation in the quality of gas, and it would do more justice to those who supplied it. He would add that he personally tried some of the experiments with Mr. Dibdin's burner and found that under widely varying conditions the amount of light given out in the photometer was practically constant.

Mr. J Methven said he had been watching the behaviour of this pentane standard of Mr. Dibdin during the last few months, and had compared it against candles. He had had half a dozen operators at work, who had made 500 separate experiments, and it was found, as the result of the average, that the power of the burner was equal to 10·283 candles. Of course it ought to be equal to 10, and he was glad to have the opportunity of stating the result of these experiments, because, naturally, an increase of nearly 3 per cent. on the 10-candle was almost equal to half a candle on 16-candle gas, and inasmuch as the extra enrichment of half a candle would cost the gas companies of London about a halfpenny, it was obvious how they would be affected by that additional value being put on the standard. It seemed rather hard on gas com-

Digitized by Google

panies to have to submit to the introduction of a standard which was nearly 3 per cent. higher than the result of experiments on 500 candles. Mr. Dibdin seemed rather to regret that the committee had introduced any alterations in the mode of consuming the gas to be tested, but he thought they had not gone far enough, because one very important matter in settling the question of these standards was to determine the photometer in which they were to be used. Without casting any reflection on the manner in which the committee made their experiments, he thought the importance of the subject required that further investigation should be made before a new standard was introduced.

Mr. J. Cadett said he had used the pentane-Argand, both the 2 c.p. and the 10 c.p, during the last two years as a standard for photographic purposes. In such cases they did not expect to work to three places of decimals of a candle, but as far as they could observe, using ordinary care, they were quite unable to notice any difference in testing with the pentane-Argand.

Mr. Lloyd said that everyone was interested in having a thoroughly reliable standard, but he held that it was better to take the improved standards as they were invented than to defer giving up the candles until perfection had been reached.

Colonel Allan Cunningham, R E., thought they had had brought before them a standard of light which he hoped would have a wider use than the testing of pure gas only. It might be used to test the illuminating qualities of petroleum, etc., or for photographic exposures or other scientific purposes. He thought that in testing this standard burner more attention should have been paid to the effects of varying pressure of the atmosphere. This could be ascertained by comparing the burner with an incandescent lamp, which, being enclosed, was not affected by change of pressure.

Mr. Campbell said that the effect of the presence of carbonic acid in the air had not been touched on. From experiments in Germany he believed that the influence of CO_2 was great. The addition of 1 part in 1,000 made a difference, he believed, of 7 per cent. in the amylacetate standard.

Mr. Grafton referred to some former experiments of Mr. Dibdin, which seemed to show that his light was equal to 16·7 candles by Mr. Harcourt's one-candle standard and Mr. Methven's two-candle standard. He personally had conducted some 3,000 tests, and could not get it to average 10 candles.

Mr. Lacey said he had used this standard ever since it was first mooted in his ordinary daily work, and had found it very convenient and accurate. He thought the accuracy and uniformity of more importance than any small error in actually candle-power. He preferred a 10-candle standard to a 16-candle one.

Mr. C. E. Hearson asked if pentane could be readily obtained, and whether there would be any difficulty with regard to its carriage, on account of its inflammatory nature.

Mr. Dibdin, in reply, said he had found no difficulty in procuring pentane, and it generally came by carrier, as it was no more dangerous than ordinary benzolene or ether, and many other things which were systematically conveyed about the country. Taking the points raised in order, Mr. Methven said an average of 500 experiments gave a value of 10·283 candles for this standard. Against this he had to place his own experiments, which numbered about 2,000, and those made by the members of the committee and others must have amounted to about 10,000, so that there were about 12,000 against 500. He could not cavil at Mr. Methven's results, but an average derived from 10,000 or 12,000 experiments must outweigh an average of 500. The question of photometers could now be settled without going to Parliament, because the referees had full powers, and he believed it was understood that when the standard was settled the referees would once for all prescribe the photometer. His own experience was that if a photometer were well ventilated it did not matter whether you had a bit of wood at the back or a velvet curtain, or something in front or at the ends, so long as you screened the eye of the observer from lights and avoided reflection from extraneous surfaces on the screen. The cabinet work did not matter. He preferred to burn lights in the open, but it did not matter much; but to surround your lights with upholstery did not seem to him the best way of doing it. When you had candles burning in a heated box, with insufficient ventilation, you could make them do whatever you liked. That was exactly what has been done in some of the experiments referred to by Mr. Methven. In some of his results he got an average of 16·3 as the value of a certain flame with the Methven two-candle screen and the Harcourt one-candle pentane flame, as against 17·0 as an average of all the results with candles. But that average of 17 0 was raised by including certain results which were obtained in a room purposely heated to a temperature of over 90deg., and the candles behaved in such a way owing to the rapid volatilisation of the sperm that they began to smoke, and gave less light. Thus the value of the gas consumed was made to appear higher, and in many cases the 16·3 average flame, when tested by the candle, appeared to be up to 18 or 19 candles. In taking the average he excluded all those results which came over 17·5. Thus, the Harcourt lamp and the Methven screen agreed, and the candles, including tests which were obviously incorrect, gave results 0·4 too high. He was obliged to Mr. Cadett and Mr. Lacey for their support. Colonel Cunningham seemed to have an idea of carrying a standard of light all over the world, which was a grand idea, but the committee of the Board of Trade recommended the adoption of this standard simply as a working standard for testing London gas, not as an absolute unit of light to be used everywhere. What would be the variation at an elevation of 7,000ft., or down in a mine, he had not had an opportunity of trying, but Mr. Vernon Harcourt had made some experiments with the one-candle unit on the tep of Ben Nevis against the light of an incandescent electric lamp, and he believed that the variation was very little, if any. If that were the case, probably the same result would be found with the 10-candle standard, as the same argument applied. The effects of dust and fog were eliminated to a great extent by the fact that the distance between the standard and the light to be tested was usually very small, so that the fog would have to be very considerable before any readable difference would be introduced. Mr. Grafton also raised the point that his chimneys were not always nicely ground at right angles, but if anyone choose to purchase something which was not what it ought to be, they must take the responsibility. He was glad to hear Mr. Lacey recognise the fact that the committee had done their best to arrive at a practical solution of the question. He thought the tone of the meeting was such as to justify the decision at which the committee had arrived.

The **Chairman**, in proposing a vote of thanks to Mr. Dibdin, said anybody who had ever had to work at photometry with candles would agree that the sooner this standard was got rid of the better. He hoped the discussion might help to educate members of Parliament, so that they might soon have a satisfactory standard for testing London gas.

The vote of thanks was carried unanimously, and the meeting adjourned.

ALTERNATE-CURRENT TRANSFORMERS.

BY DR. J. A. FLEMING, F.R.S.

The last lecture of the set of four on the above subject was delivered on Monday, and Dr. Fleming found a difficulty in completing the range of the syllabus in the limited time at his disposal. The details of testing transformers were not quite completed in the last lecture, so the measurement of the resistances of the copper circuit was the first subject referred to. Dr. Fleming advised that, when measuring the resistance of the primary winding with a Wheatstone bridge, the secondary circuit should be short-circuited to reduce the self-induction effects. He also recommended that the low resistance of the secondary windings should be measured by the potentiometer method. The measurement should be made both when the transformer was cold and also after a long period of load. The variation of resistance would then give a good indication of the actual temperature rise in the body of the transformer. Having obtained thus the copper losses and also the iron loss, a curve of total loss at any load could be constructed which would be useful in computing the all-day efficiency of a transformer with a given load curve. The lecturer went back to the subject of fall of potential on full load. He explained that the total loss of pressure was made up of two components—*i.e.*, the copper drop and the drop due to magnetic leakage. The following diagram shows an excellent method of determining the total drop, but it necessitates the use of two transformers. As will be seen, it is a differential method, and

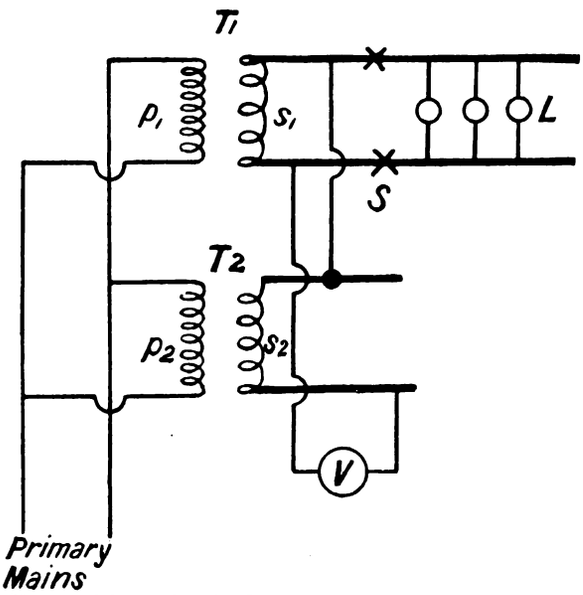

Diagram of Connections for Testing Total Drop in Transformers.

hence a small alteration in the pressure on the mains will not affect the reading much. The voltmeter used must be an electrostatic one, and must be capable of reading from one volt upwards. A delicate electrostatic instrument designed by Messrs. Ayrton and Mather was recommended for the purpose. Referring to the leakage question, Dr. Fleming said that a mercury thermometer would give indications of magnetic leakage, as the eddy currents in the mercury would cause an apparently high temperature as compared with a spirit thermometer. The action of peaked E.M.F. curve was stated to increase the leakage effects, although the same curve tended to reduce the hysteresis loss. A few examples of the use of magnetic leakage to obtain a constant current from constant pressure were given by illustrations of the Thomson-Houston constant-current transformer,

Digitized by Google

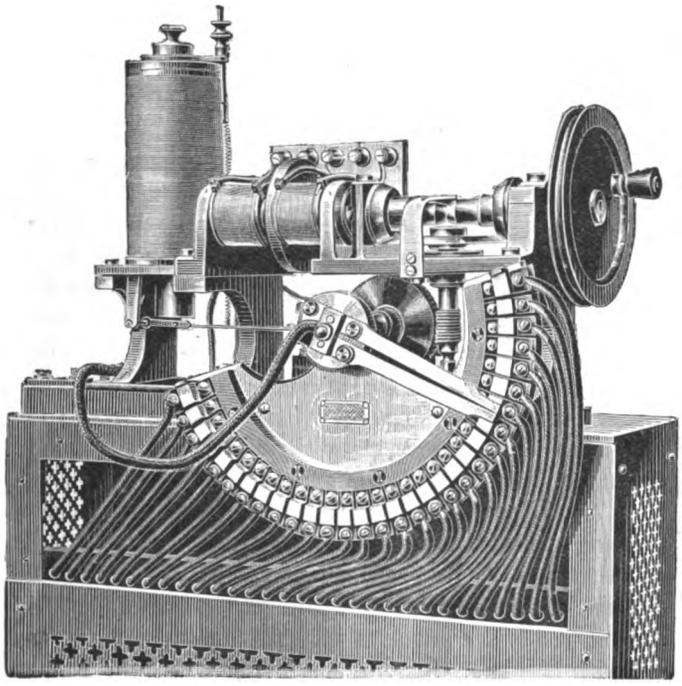
etc. The lecturer then dealt very briefly with the interesting subject of the alteration of the hysteresis loss with time. Unfortunately, the time at his disposal prevented him giving more than a few general remarks, from which no definite conclusions could be drawn.

The next subject—*i.e.*, that of resonance effects in alternating circuits containing capacity and self-induction—also suffered very much from the limited time. Some interesting analogies were shown, and from them the now well-known conclusions that no alternating-current circuit should be suddenly interrupted or made were discussed. Then, after briefly referring to the skin effect in large conductors, whereby the resistance to alternating currents becomes larger than that due to ohmic resistance only, the lecturer closed the series of lectures with a few general remarks.

A hearty vote of thanks, proposed by the Chairman (Sir H. Trueman Wood), was then given to Dr. Fleming.

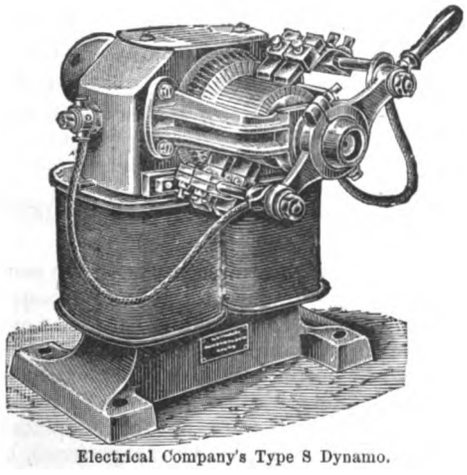
THE ELECTRICAL COMPANY, LIMITED.

The price-list of dynamos and motors issued for 1896 by the Electrical Company, Limited, of 122, Charing Cross-road, W.C., consists of about 55 large square pages, giving in tabular form such information as to the machines manu-



Electrical Company's Automatic Regulator.

factured by the company that when the requirements and conditions are given it is a simple matter to find the machine to fit them. The dynamos and motors are classed by types quoted by letters, and an illustration of each type heads the page. The machines of the same type



Electrical Company's Type S Dynamo.

are then arranged vertically, according to their E.M.F., while the successive columns, read horizontally, give the current, speed, consumption, weight, price, and other details as to accessories required. The list is most methodical in its arrangement, the book presenting the appearance of a succession of tables; and it is noteworthy that the weights and dimensions throughout are given in the metric system. Nearly half the book is concerned with continuous-current machines, this section closing with two pages devoted to directly-coupled engines and dynamos. Small motors for drills, sewing machines, fans, etc., follow, and are succeeded by regulators, resistances, couplings, etc., alternating-current, three-phase, and single-phase motors coming at the end of the list. We reproduce above the illustrations of the company's type "S" dynamo and their automatic regulator.

WHAT, WHEN, AND WHERE.

Institution of Civil Engineers.

February 14, 8 p.m.—Students' meeting. "The Construction of the Molong to Forbes Railway, New South Wales," by Sidney Thow, Stud.Inst.C.E.

February 18, 8 p.m.—Ordinary meeting. Paper to be further discussed. "The Manufacture of Aluminium by Electrolysis, and the Plant at Niagara for its Extraction," by A. E. Hunt, M.I.C.E.

Institution of Electrical Engineers.

February 21, 8 p.m.—At 28, Victoria-street. Students' meeting. "Some Central-Station Experience," by W. Fennell (student)

Royal Institution of Great Britain.

February 21, 9 p.m.—At Albemarle-street, Piccadilly. "The Past, Present, and Future Water Supply of London," by Edwd. Frankland, D.C.L., LL.D., F.R.S., M.R.I.

Society of Arts.

February 17, 8 p.m.—At John-street, Adelphi. "The Chemistry of Metals and Alloys Employed for Building and Decorative Purposes," by Prof. J. M. Thomson, F.R.S.E. (first of three lectures).

February 18, 8 p m.—Foreign and Colonial Section. "The Development of Electrical Traction Apparatus," by H. F. Parshall (General Electric Company, U.S.A).

Royal Meteorological Society.

February 19, 7.30 p.m.—At 25, Great George-street, Westminster. "Report on the Phenological Observations for 1895," by E. Mawley, F.R.H.S., president; "Notes on the Recent Unusually High Barometer Readings in the British Isles," by Robert H. Scott, M A., F R S.; "Turner's Representations of Lightning," by R. Inwards, F.R.Met.Soc., F.R.A.S.

Physical Society.

February 14.—Annual general meeting. "The Determination of High Temperatures with the Meldometer," by W. Ramsey and N. Eumorfopoulos.

City and Guilds Technical College.

February 20.—At the College, Leonard-street, Finsbury. Conversazione, concert, and dance. Lecture on "Invisible Light," by Prof. Silvanus P. Thompson. Exhibition of models, etc.

Engineering Society.

February 14, 4 p.m.—At King's College, Strand, W.C. "The Time-Rate of Growth of Magnetism of Iron and its Importance to the Electrical Engineer" (with experiments), by E. Wilson, M.I.E.E.

Institution of Junior Engineers.

February 14, 8 p.m.—"The Stability of Tall Chimneys," by F. J. Bancroft, B.Sc. (member).

North-East Coast Institution of Engineers and Shipbuilders.

February 14, 7.30 p.m.—At Lecture Hall of Literary and Philosophical Society, Newcastle-upon-Tyne. Ordinary meeting. "Some Structural Details of Modern Ships," by M. C. James.

Liverpool Engineering Society.

February 19, 8 p.m.—At the Royal Institution, Colquitt-street. Eighth ordinary meeting. "Light Railways: Conditions Affecting their Construction and Working," by Alexander Ross, M.I.C.E.

INSTITUTION OF ELECTRICAL ENGINEERS, Feb. 13.

DR. HOPKINSON (President) in the chair.

At last night's meeting of the Institution the following candidates were elected:

Associates.—Charles Henry Biggs, Glebe Lodge, Champion Hill, S.E.; Alfred W. Fell, 7, Elborow-street, Rugby; Frederick Richard Flew, 5, Glazbury-road, West Kensington, W.; Albert E. Mohring, 59, St. George-street, E.; William Edward Moulsdale, superintendent engineer, Ocean S.S. Co., Singapore; Gilbert C. Vyle, National Telephone Co, Nottingham.

Students.—F. R. Bridger, 26, Priory-road, West Hampstead, N.W.; William Bunn, 8, Albert-road, Stroud Green, London, N.; Eric Mortimer, Technical College, Finsbury; Claud Edward Vance, "Warden," Esmond-road, Bedford Park, W.

TO CORRESPONDENTS.

All Rights Reserved. *Secretaries and Managers of Companies are invited to furnish Notice of Meetings, Issue of New Shares, Installations, Contracts, and any information connected with Electrical Engineering which may be interesting to our readers. Inventors are informed that any account of their inventions submitted to us will receive our best consideration.*

All communications intended for the Editor should be addressed C. H. W. Biggs, *139-140, Salisbury Court, Fleet Street, London, E.C. Anonymous communications will not be noticed.*

TO ADVERTISERS.

Advertisements should be addressed to the Publisher, 139-140, Salisbury Court, Fleet Street, E.C., and should reach him not later than noon of Thursday. **Special Terms** *for a series can be arranged on application.*

"SITUATIONS VACANT" and "WANT PLACES" Advertisements will be charged at THREE WORDS for ONE PENNY with a MINIMUM charge of SIXPENCE.

TO SUBSCRIBERS.

"The Electrical Engineer" *can be had by Order, from any Newsagent in Town or Country, and at the various Railway Stations; or it can, if preferred, be supplied direct from the Office on the following terms:*

	3 months.	6 months.	12 months.
United Kingdom	3s. 3d.	6s. 6d.	13s. 0d.
Other Places	4s. 11d.	9s. 9d.	19s. 6d.

(Post Free, Payable in Advance.)

Cheques, Post Office and Postal Orders for Subscription and Advertisements should be made payable to C. H. W. Biggs, *139-140, Salisbury Court, Fleet Street, London, and be crossed "Union Bank."*

BOUND VOLUMES.

Vol. XV. of new series of "The Electrical Engineer" can be had bound in blue cloth, gilt lettered, price 8s. 6d. Subscribers can have their own copies bound for 2s. 6d., or covers for binding can be obtained, price 2s.

A PROTEST.

We have this week inserted two letters from Messrs. Walker and New with a view, among other things, to utter an emphatic protest against the tendency of modern *fin-de-siecle* men to write such letters. Take Mr. Walker's letter first, as it may be deemed the more important, for therein is claimed that the author long since propounded a theory which the discoveries of recent months are said to support. Now, any man is perfectly justified in getting his theories made public, and in pointing out anything that seems to him to support those theories. Had Mr. Walker stopped there we had nothing to say, but we must and do protest against his view that the technical Press is dominated by the opinions of professors. If Mr. Walker's views commended themselves to the various persons responsible for the different papers, they would be pleased to give those views publicity whatever the opinions of professors. Writers seem to imagine that technical papers are at their beck and call, and under no circumstances ought a letter or article to be rejected. But there is more than one person to be considered in the matter, and we are quite sure that the various editors against whom complaint is made can advance reasons for their action. The modern style of suggesting personal bias in matters journalistic is, in our ideas, a mistake, and to be avoided. "You're another" is not argument—and this brings us to Mr. New's letter. The good taste of our contemporary in giving parallel extracts may be questioned, but a little license may be allowed under the circumstances that existed. Is life worth living, however, if every man is to be pinned down to his views of ten, fifteen, or twenty years back? With fuller information opinions must change, and the man is not worth his salt if he is afraid to say, "I thought so then, but I do not think so now." We wish writers and readers would credit others besides themselves with the desire to do right, and hanker less about "personalities" than about information. There seems to be a greater delight in getting a rise out of somebody than in obtaining information. So long as the laugh is not against themselves people seem to delight in the personalities, hence the success of the so-called society papers. If that style of thinking is to dominate business men, the sooner the end comes the better. The nobler view is to believe other people in earnest as well as ourselves, and to prefer to see the good that exists, rather than to revel in the bad.

THE UNIVERSAL ELECTRICAL DIRECTORY.

The publishers of this directory must be congratulated upon the great improvements they have introduced. Every effort seems to have been made to secure ease of reference, and the number of names inserted has largely increased. A directory to be useful must be fairly accurate. Perfect accuracy is impossible, because from week to week movements are made which were not contemplated when a particular address was given. Our experience, however, is that this directory is carefully corrected, and may be relied upon for accuracy of address and description. It gives the names and addresses of those engaged in the industry in Great Britain, India, the Colonies, America, the Continent,

Digitized by Google

etc.—in fact, agreeing with its title "Universal," and must undoubtedly become a necessary work of reference in every house of business so far as the electrical industry is concerned, and we should say will be indispensable in many other cognate branches of industry.

CORRESPONDENCE.

"One man's word is no man's word,
Justice needs that both be heard."

ELECTRICITY A MODE OF MOTION.

SIR,—I am very pleased that my attempts to solve the problem in which we are all so deeply interested are at last awakening the interest of thinking men, more particularly as there would appear to be a determined attempt on the part of the editors of certain papers calling themselves scientific to "burke" discussion on this subject, unless the writer who attempts to discuss happens to be teaching physics in a college, and obscures his subject more or less with a lot of useless mathematics. It appears to me to be a singularly foolish attempt to turn the dial of progress backward. Fancy, in an age when everyone who thinks at all is doing all he can to help education forward, and to teach men, above all things, to think, the editors of papers that are supposed to represent advanced scientific thought attempting to stifle thought on the part of those to whom thought—deep and earnest thought, is a necessity of the existence of the work they are engaged on.

May I also mention, before replying to Mr. Avery's able and pertinent questions, that I trust he and others will understand that the theory I have ventured to propound did not spring from my brain full grown, like Minerva from the head of Jove. Readers of your paper will have noticed, if they have read my contributions to your columns for some years past, that the views I now hold were formed very gradually, and that even after I ventured to launch the theory very much remained to be done in the matter of developing it in all its bearings. Very much, even now, still remains to be developed, and it is for this reason I so gladly welcome intelligent criticism such as that contained in Mr. Avery's letter. May I add that I venture to hope for his co-operation, and that of other readers who are interested in the matter, in putting the theory if, as I hope and believe it is scientifically correct, upon a firmly established basis.

And now to reply to Mr. Avery's queries. First, why should electricity and electromagnetism be placed so far apart? Perhaps I had better explain that I look upon magnetism and electromagnetism as two entirely different forms of motion. It is electromagnetism that I place beyond the ultra-violet rays, because it appears to me there is no other place for it, unless its place be somewhere within the region of the spectrum, but with a motion of a different character to that of the heat and light rays. It cannot come between electricity and heat because, as we know, the smallest resistance placed in the path of the electric wave instantly results in conversion of a portion of its energy into heat waves.

It may have a particular form of motion of its own within the range of the spectrum, but we have no evidence pointing that way, and, on the other hand, we have evidence pointing distinctly to a very high rate of motion—viz., the great resistance offered to the wave-motion—by the insulating envelope of the conductor, and the necessarily very great increase in the rate of the wave-motion and decrease in the wave-length.

Next, as to the solenoid. My remark above will have cleared the ground in this matter. I look upon magnetism as energy, molecular and ethereal motion, stored in the molecules of the iron at their creation. The motions are more or less masked by the conditions under which the iron molecules exist, and their presence is not always apparent. In pure iron, however, we have these motions, as I understand them, in full vigour; but when in what we call the non-magnetic state they are again masked by the closed figures formed by the molecules themselves, the motions passing round and round each group.

When we magnetise an iron bar, as we express it, in my view, we set free these motions and make them visible outside the bar, just as we may render visible the energy stored in a suspended body by removing its support. Hence it follows that it is not necessary for the waves to pass through the states we know as heat and light. What particular form of motion magnetism is, and where it should be placed, requires further study. That the direction of propagation of its motion is not the same as the direction of the electromagnetic wave, a little consideration will, I think, make apparent.

Further, it appears to me that a careful study of the attractions exhibited by magnets and electromagnets, using the terms in the ordinary manner common at present, and of electrostatically-charged bodies, should lead us on towards the solution of that more important question, What is gravitation? Next, as to the changes of the wave-lengths from electric waves to invisible heat, then red and on to violet and ultra-violet. Mr. Avery asks if we go on increasing the current, should we not obtain pure magnetism? I will substitute for this pure electromagnetism, following on the view I have expressed above as to what I conceive magnetism to be. My view on this matter is that undoubtedly you will obtain electromagnetism, but probably not alone; and this is what I make out that Prof. Röntgen has obtained. You have to remember that if you go on increasing the electric current passing in a metal conductor to this extent, you will alter the physical state of the conductor long before you have arrived at the rate of vibration at which I conceive that electromagnetism begins.

If you can imitate the conditions that you would have, if you could go on increasing the rate of vibrations without altering the physical condition of the conductor, you do obtain electromagnetic waves—viz., in the media surrounding an insulated conductor in which an electric current is passing; and, also, as I think, in Prof. Röntjen's experiments.

Next, as to why the waves, which I conceive an electric current to consist of, take the path of the conductor instead of the majority of them diverging into space? I should like to join with this question an objection that was made to me by an eminent practical electrical engineer a short time since. "I agree with you in part," said this gentleman, "but I do not see how you get over the difficulty that different waves corresponding to different physical forces occur in different media."

The answer to both questions is, I think, the same. It appears to me that the motions, wave-motions principally, of which the physical forces consist, take place both among the molecules of the body in which the particular force is manifest and in the ether as well. Naturally, what may be called the coarser motions, the long, slow waves, are more apparent in the molecules of the body itself, because they have the power to move those molecules. As the rates of motion increase, and the wave-lengths and the amplitude of the vibrations decrease, the waves have less and less power over the molecules themselves and become more and more confined entirely to the ether. Sound waves, for instance, being the longest, are almost wholly confined to the molecules of the bodies through which they pass. Heat waves pass largely by means of the ether, but they must undoubtedly also move the molecules of heated bodies, as all bodies take up a larger space under the influence of heat. Light waves, that is to say, the shorter waves of the spectrum, pass more by way of the ether, though they, too, are present also among the molecules of luminous bodies. I am not quite clear as to Mr. Avery's last question. As I understand the matter, as the rate of vibration increases as you confine the motion, whether among the molecules of the body or in the ether, the wave-length decreases and the rate of transmission of the wave increases and *vice versâ*. I trust that Mr. Avery will return to the charge, and that others will also join in the discussion.—Yours, etc.,

SYDNEY F. WALKER.

Cardiff Electrical Works, Severn-road, Cardiff.

USEFUL ELECTRIC LAMPS.

SIR,—There is something pathetic in the manner in which the English cling to the delusion of the supremacy of British manufactures. A much wiser commercial policy is to own up manfully when we are beaten by our foreign

Digitized by Google

competitors; by so much the sooner will the country realise its deficiences and thus regain its rapidly declining position in the world's market.

I am led to pursue this somewhat hackneyed reflection by the perusal of a letter from Mr. Frederick Walker in your last issue, wherein he states that English-made lamps are superior in every point of efficiency to any imported from abroad. Much as I should like to support his statement on patriotic grounds, I regret I am unable to do so.

English makers have not yet succeeded in turning out a successfully commercial and economical 8-c.p. lamp even at 115 volts.

Referring now more particularly to lamps of higher voltage, if English makers would cease "sounding notes of warning" and sound the depths of their inventive faculties instead, they might be more profitably employed both for themselves and their countrymen.

While certain energetic and farseeing manufacturers are busily engaged perfecting their lamps and hedging them round with valuable patents, the English manufacturer goes on sounding his note of warning and assuring the public that a reliable high-voltage lamp cannot be made.

It is obvious that defective German or foreign lamps are to be met with. We find good and bad English lamps even amongst those of ordinary voltage, but there is no shadow of doubt that up to the present certain foreign-made high-voltage lamps are infinitely superior to anything of the kind made in England.—Yours, etc.,

February 12, 1896. SYDNEY W. BAYNES.

COMPARISON.

SIR,—The following extracts may be of some interest or amusement to your numerous readers.

The *Electrical Review* of January 31, 1896, gives us the following with regard to the Hall *v.* Alabaster and Co. case:

MR. LAWSON WALTON, Q.C., FOR AND AGAINST.

Mr. Lawson Walton appeared for us against Dr. Tibbitts in February, 1893, and made us blush by saying:	Mr. Lawson Walton appeared against us in the Hall case, and said:
"Mr. Alabaster and Mr. Gatehouse and Mr. Kempe founded the *Electrical Review*. . . . They were all scientific men, who were specially responsible for the article which was impugned, were men of some eminence in a profession which involved a knowledge of electricity. They . . . were men who could form an opinion of some weight."	"The defendants were a trade journal, and their news columns were largely devoted to describing the machines and operations which they advertised."

Compare with:

Mr. Frank King in his evidence in the above mentioned trial stated:	Mr. Frank King in his patent specification No. 1,731 of 1895 (in combination with Mr. Faure) claims the following:
"He had had a very large and distressing experience in the use of celluloid in the cells. He had used a great number of tons of it. Celluloid had been discarded as giving an additional mechanical strength to those plates."	"In or for secondary batteries the use of a sheet of silicated asbestos fabric, such as is hereinbefore described in combination with perforated celluloid, ebonite, or other sufficiently acid-resisting material for retaining the active material in place as above set forth."

I wonder which discrepancy is the more unwarrantable, and whether imitation is still the sincerest form of flattery? Yours, etc., ANTHONY G. NEW.

10, Bridge-street, Westminster, S.W., February 12, 1896.

SOUND CASTINGS FOR ELECTRICAL WORK.

SIR,—In reply to the question of "Reader" in your issue of February 7, I am not surprised that he failed to obtain ferro-sodium of Glasgow chemists, or, for that matter, ferro-manganese, ferro-silicon, or other iron alloys used in iron or steel working. Chemists do not supply such things, they not being in general demand. The only makers of ferro-sodium in this or any other country is the Ferro-Sodium Company, Limited, whose Scottish agents are the Ironfounders' Grinding Company, of 3, West Scotland-street, Glasgow. As to what ferro-sodium is, it may be well to say that it is an alloy of iron and sodium, both chemically and mechanically combined, and that, used as directed, it causes the production of absolutely sound castings.—Yours, etc., WALTER J. MAY.

February 8, 1896.

THE TELEPHONE QUESTION.*

BY ALFRED R. BENNETT, M.I.E.E.

The interest which the telephone question is exciting in Scotland and the country generally at the present time must be my excuse for troubling the members of the East of Scotland Engineering Association with a paper partaking more of an economical than of a technical character. British engineers and manufacturers have at present, owing to the backward and exclusive position of the industry, but few opportunities for contributing to the advancement of telephony, and their first solicitude should be the creation of a field in which their talents may be exercised; then technical considerations may with more propriety receive attention. Several important facts connected with the telephone question have recently been presented in a manner which advocates of the existing state of matters in the United Kingdom have not seen their way to challenge.

These facts may be briefly summarised as follows:

(1) That in the great majority of foreign countries the rates of subscription paid by telephone subscribers are notably lower than those exacted in the United Kingdom. In some countries the difference is scarcely credible, as the subscription, including erection and maintenance of all necessary wires and instruments, descends as low as £2. 14s. 4d., £2. 9s. 6d., and even £1. 13s. 4d. per annum.

(2) That in many foreign countries the telephonic development greatly exceeds that which has been attained in the United Kingdom. This development in many places has reached such a stage that there is one telephone to every 30 inhabitants, including women and children, while in a few localities the proportion is as high as one telephone in 20 and one telephone in 18. When it is stated that in the United Kingdom the proportion, according to the latest published figures, is 1 in 636, the amount of lost ground which we have to make up will be appreciated.

(3) That the difference in the charges between Continental countries and the United Kingdom is not caused by cheapness of labour, or cheapness of materials abroad, as it has been proved that, as a rule, foreign companies and administrations pay their servants at least as well as we do ours, and not infrequently better, and that their apparatus costs them more.

(4) That the greatest degrees of development are attained by means of local enterprise, those countries which allow local companies to do the telephonic work standing at the head of the list, not only as regards the number of telephones to population, but as regards cheapness of subscription and general efficiency.

(5) That the telephone is put to more numerous uses abroad than it is in the United Kingdom, so that although the foreign telephone subscriber pays less for his connection, he gets a variety of uses out of it which are unknown here.

(6) That municipal enterprise has been successfully applied to the management of telephone exchanges, so that one of the best worked exchanges, and at the same time one of the cheapest, is owned and worked by a town council.

(7) That competition between two telephone companies within the same area has a stimulating effect on the growth of telephonic work, while it is not inimical to good service. Competition does not exist in many countries, but wherever it shows itself its effects are at once apparent by the low rates which prevail and the high stage of development attained.

It would be superfluous to repeat here proofs which have been given of the truth of the foregoing statements, as each and all of them have been severally examined and discussed publicly during the last six months. I shall, therefore, ask you to accept them as true. The question then arises, why cannot the circumstances which have led to such good results abroad be repeated at home?

The answer is furnished (1) by the existence in the hands of one company of a complete monopoly of the telephone exchange business in the United Kingdom, with the exception of a few insignificant exchanges owned by the Post Office; (2) by the policy of the Post Office, which is to support the monopoly possessed by that company.

While advocating in the House of Commons the conclusion of the agreement between the Post Office and the National Telephone Company, by which, in return for several valuable concessions, the company consented to sell its trunk lines to the Post Office, the two last Postmasters-General, Sir James Fergusson and Mr. Arnold Morley, deprecated the idea of investing any company with a monopoly, and, when the danger of such a situation being created was urged, pointed to the

* Paper read before the East of Scotland Engineering Association at Edinburgh, February 5, 1896.

Digitized by Google

clause in the proposed agreement which reserved the right of the Post Office to grant new competing licenses if necessary, so that the public would always possess a remedy against bad service or high rates; and on these assurances the agreement was allowed to be passed, although many members of Parliament expected, from the wording of the report of the Select Committee, which had recommended the agreement, that an opportunity would be afforded them of inspecting it in its final form before signature, which expectation, however, proved illusive, as the late Government refused to permit anything of the kind being done.

Relying on this clause in the agreement, and on the reiterated statement in the House that the Post Office had reserved the right to grant additional licenses, the Corporation of Glasgow, in which town the service given by the National Telephone Company had come to be regarded as unsatisfactory, applied for a license to erect and work a telephone exchange of its own. Without opposing a direct negative to the application, the Postmaster-General refused it in effect by prevaricating about his promise to grant additional licenses, and by seeking to give that undertaking a different interpretation to the meaning which it bore in plain English, and to the meaning which had without suspicion been assigned to it by those members of Parliament who were anxious for telephonic reform.

(To be continued.)

ABERDEEN ELECTRIC LIGHTING ACCOUNTS.

The accounts of the past year's working of the Aberdeen Corporation electric light station have just been issued. The loans sanctioned under the provisional order amount to £32,000, of which £29,800 has been borrowed.

COMPANIES' MEETINGS AND REPORTS.

ANGLO-AMERICAN TELEGRAPH COMPANY, LIMITED.

The ordinary half-yearly general meeting of this Company was held last Friday at Winchester House, E.C., the Marquis of Tweeddale presiding.

The **Chairman**, in moving the adoption of the report, said that it was the best that had been presented to the shareholders since 1892. In the half-year ending 1892 there was paid a dividend of £1. 10s. per cent.; in 1893 it fell to £1. 6s.; in 1894 to £1. 3s; but this half-year the Board were able to recommend a dividend for the half year at the rate of £1. 8s., of which 10s. had already been paid, leaving a balance of 18s. The increased dividend was due, first, to improved traffics; secondly, to an increase in the receipts from the steamship "Minia"; and, thirdly, to a considerable reduction in their expenses. The increase in traffic amounted to £15,764, due, of course, to the great improvement which had taken place in commerce and business. The "Minia" had earned £1 350 more than last year, and the decrease of expenses amounted to £1,056. That decrease in expenditure was all the more satisfactory, inasmuch as it compared with the half year when the decrease amounted to no less than £3 399. Since 1891 the expenses showed a total decrease of £8,712. The renewal fund now stood at £624,265, and the value of the securities held by the Company had increased by no less than £74,000. Owing to the lease of their offices in Threadneedle-street coming to a termination, the Board had purchased for £28,541 the lease for 13 years of very suitable premises in Old Broad-street. The new offices were superior to the old ones, and by letting off a certain portion of the building the cost to them would be practically the same as they had previously paid. Their cables were in a very satisfactory condition. It was true that during the half-year they had not been altogether free from interruptions, but, with the exception of the 1873 cable, which was interrupted in the preceding half-year and repaired on July 16, the interruptions had been confined to their short cables west of Newfoundland and to their cable in the shallow sea. The repairs had been executed with that skill and promptitude always exhibited by their officials, both in the ship "Minia," commanded by Captain Trott, and by their local officials at St. Pierre, who, in face of great difficulties from

Digitized by Google

the weather and other causes, repaired one of their most important short cables with perfect success. He was sorry to say that the French case was very little nearer a settlement than it was when he last met them. He need hardly say that it was not from any want of energy on the part of the Company, but the French lawyers, being not unlike our own, were not disposed to be in too great a hurry in the settlement of such matters. He was glad to say that the new half-year had commenced in a manner which augured very well for the current six months. The Chairman concluded by moving: "That the report of the directors and accompanying statement of accounts to December 31, 1895, submitted to this meeting be, and the same are hereby received and adopted, and that the following dividends as recommended by the Board be now declared and paid, less income tax—that is to say: (1) a final dividend of 18s. per cent. upon the ordinary consolidated stock for the year ending December 31, 1895 (making, with £1. 11s. per cent. interim dividends already declared and paid by the Board by way of dividends on account) a total dividend for the said year of £2. 9s. per cent on the said stock; (2) a final dividend of £1. 16s. per cent. upon the preferred ordinary stock for the year ending December 31, 1895, making, with £3. 2s. per cent interim dividends already declared and paid by the Board by way of dividends on account, a total dividend for the said year of £4. 18s. per cent. on the said stock."

Mr. F. A Bevan seconded the resolution.

Mr. Garner asked for some information as to the probable limit of the renewal fund. Cables could be repaired much easier to-day than formerly.

Mr. Wood said that steps ought to be taken, if possible, to expedite the French case, and **Mr. Davis** thought the shareholders ought to be told more fully how the case stood. If they did not expect to receive much, the matter ought to be concluded.

Mr. Griffith said it was preposterous that half-year after half-year the case should still be pending. They could not suppose that the judges of the highest courts in France were deliberately doing something to keep the case back.

In reply, the **Chairman** said the Company's legal advisers here and in France were doing all they could, but they could not force the case before the Court of Appeal any quicker than the authorities were willing to take it. There was no delay on the part of the Company. He must say distinctly that the Board did not expect to get any substantial sum as the result of the settlement of the case. In his opinion, the French Cable Company would not be able to pay any very heavy damages if they were awarded. As to the renewal fund, he was unable to say definitely what amount it should reach before being considered large enough. Their cables were growing older every day, and when they were newer it was thought that £1,000 000 would be barely sufficient to make them feel quite confident of being able to keep their four cables in good working order.

Mr. C Burt was afraid the discussion that had taken place on the case might have a prejudicial effect so far as they were concerned. Having gone so far, and paid almost every item of costs they had to pay up to the present time, they would surely go on with the case and obtain a final decision after striving for so many years to get justice done to them.

The resolution was subsequently agreed to unanimously.

WATERLOO AND CITY RAILWAY COMPANY.

The half-yearly general meeting of the Waterloo and City Railway Company was held last week in the Board-room at Waterloo Terminus.

The **Chairman**, in moving the adoption of the report, said that the total amount of share capital received was £216,000, of which they had expended £122,736. The capital expenditure during the period under review amounted to £62,321, and it was estimated that during the next six months £105,000 would be expended. To provide for a part of this money it was probable that a further call would have to be made.

KENSINGTON AND KNIGHTSBRIDGE ELECTRIC LIGHTING COMPANY, LIMITED.

Directors: Alfred Sohier Bolton, Esq.; Sir. Frederick J. Bramwell, Bart., F.R.S.; G H. Hopkinson, Esq; Granville R. Ryder, Esq; R. W. Wallace, Esq., Q C.

Directors' report to be presented at the ninth ordinary general meeting to be held at 1, Great George-street, Westminster, on Thursday, February 20, 1896, at 5 p.m.:

The directors submit to the shareholders a statement of the accounts of the Company, together with a report of the position of the undertaking at the end of the year 1895. The mains, which extended to a length of 18¾ miles on December 31, 1894, have been increased during the year 1895 to 20 miles During the year the number of houses and shops connected with the system has increased from 908 on December 31, 1894 to 1,109 on December 31, 1895; while the number of lamps calculated on the usual basis of 8 c.p. has increased from 80,678 to 94,780. The debenture debt of the Company has been converted from 4½ per cent. first mortgage debentures to 4 per cent. debenture stock. The debentures were paid off at £105 by new stock issued to the holders. Further issues of debenture stock have since been made, £6,800 at £103 and £15,755 at £105 per cent., of which amount £11,780. 15s. was paid by December 31. The directors have thought it advisable to appropriate the balance of premiums thus obtained, after deducting the expenses of creation and issue of this stock, to the reduction of the cost of conversion. The directors have written £1,000 off the goodwill account, and strengthened the renewal account by transferring to it £4,270. 2s. 11d., making the total amount placed to that account £9,990. 13s. 8d. After providing for the above amounts and paying the dividends on the 6 per cent. first preference shares to June 30, 1895, on the 5 per cent. second preference shares to September 30, 1895, and an interim dividend at the rate of 5 per cent. per annum on the ordinary shares for the first half of the year, the balance standing to the credit of the net revenue account for the year 1895 is £5,227. 7s. 6d. Of the above sum £1,450 has been appropriated to the payment of the first preference dividend to the end of the year, and £150 has to be set aside to meet the portion of the dividend on the second preference shares accrued to the same date, leaving £3,627. 7s. 6d., out of which it is proposed to pay a further dividend on the ordinary shares at the rate of 7 per cent per annum for the past half-year, making, with the interim dividend paid to June 30, 6 per cent. for the year. This will leave a balance of £1,089 17s 6d. No provision has been made in the accounts for directors' remuneration. In accordance with the articles of association, Mr. Granville R. Ryder and Mr. Alfred Sohier Bolton retire from the directorship, and, being eligible, offer themselves for re-election. The auditors, Messrs Lovelock, H. W. S. Whiffin, and Dickinson, offer themselves for re-election.

CASTNER-KELLNER ALKALI COMPANY, LIMITED.

The statutory meeting of this Company was held last week at the Cannon-street Hotel, E.C., Mr. W Mather presiding.

There was no business to be transacted, but the **Chairman** stated that the directors had secured a very eligible site for the erection of the works at Weston Point, on the estuary of the Mersey. The building of the works had commenced, and would be pursued with the utmost diligence. The Company did not stand alone in beginning the electrolytic process in connection with a large chemical industry. One of their largest shareholders was the Deutsche Solvay Werke Gesellschaft, the directors of it having been so far satisfied with the investigations they had made in the Castner-Kellner electrolytic processes that they had not only subscribed largely to the capital of the Company, but had determined to erect works in Germany simultaneously with the works now being erected in England. The Board had thought it desirable at present to confine themselves to one-fourth of the plant ultimately contemplated, and to get such advantage as time and experience would give them before proceeding with the remainder.

LIVERPOOL OVERHEAD RAILWAY.

The half-yearly general meeting was held on Tuesday at Liverpool, Sir William Forwood presiding.

The **Chairman**, in moving the adoption of the report, congratulated the shareholders on the increasing prosperity of the Company, the shares of which were now quoted at 13, against 5 formerly. The line was being maintained in the best possible condition, and over 98 per cent. of the trains were run on time, being a record performance, and spoke well for electricity as motive power.

The report was adopted.

INDIA RUBBER, GUTTA PERCHA, AND TELEGRAPH WORKS COMPANY, LIMITED.

Directors: S. Wm. Silver, Esq. (chairman), Abraham Scott, Esq., Matthew Gray, Esq. (managing director), the Hon. Henry Marsham, A. Weston Jarvis, Esq.

Report of the directors for the year ending December 31, 1895, to be presented at the thirty-second ordinary general meeting of the shareholders, to be held at the Cannon-street Hotel, London, on Thursday, February 20, 1896, at 12 o'clock noon :

The annexed accounts show, after provision for doubtful debts, a net profit for the past year of £49.325. 12s Adding £20,913 17s. 4d. brought forward, and deducting £12,500 interim dividend paid in July there remains a disposable balance of £57,739 9s. 4d. The directors recommend the distribution of a dividend of 15s. a share free of income tax, amounting to £37,500, making, with the interim dividend, a total payment of 10 per cent. for the year, and leaving £20,239. 9s. 4d. to be carried forward. The year's general business has been satisfactory, and the cable department and steamships have been moderately employed. The Silvertown and Persan factories are in good order. Before the next accounts are presented the directors will propose alterations in the Company's articles of association as to the form of balance-sheet and profit and loss account in accordance with the suggestion of the auditor. The Company's 4½ per cent. debentures are repayable next month, and it is intended to issue new debentures at 4 per cent. Particulars of the new issue will be sent to the shareholders. The death of Mr. Robert Henderson in September has deprived the Board of a much-valued colleague. Mr. Silver and Mr. Scott, who retire by rotation, offer themselves for re-election as directors.

WESTMINSTER ELECTRIC SUPPLY CORPORATION, LIMITED.

Directors: The Right Hon. Lord Suffield, K.C.B., Edmund Boulnois, Esq. M P., W. Hayes Fisher, Esq , M.P., Sir Douglas Galton, K.C.B., F R.S., J. Browne Martin, Esq., James Heslop Powell, Esq., R. W. Wallace, Esq., Q.C. General manager: Captain Edmund I. Bax. Engineer-in-chief: Prof. Alex. B. W. Kennedy, LL.D., F.R S., M I.C.E. Secretary: Frank Iago, Esq.

Report of the directors to be presented to the shareholders at the ordinary general meeting to be held at the offices of the Corporation, Eccleston-place, S.W., on Wednesday, February 19, 1896, at 11 o'clock:

The Board of directors, in presenting their report and the accounts for the year 1895, are pleased to state that the business of the Corporation continues to make satisfactory progress. The supply of current, which on December 31, 1894, was provided for the equivalent of 167,703 lamps of 8 c.p., had increased by December 31, 1895, to the equivalent of 210,982 and at the present time there are on circuit the equivalent of 216 822 lamps of 8 c.p., and applications have been received for a further 6,478. The length of roadway in which mains have been laid now exceeds 39 miles, making about 156 miles of ways, into which upwards of 123 miles of copper (strip and cable) have been drawn. The plant and machinery have been working satisfactorily throughout the year, and have been fully maintained from revenue, and a further reduction has been effected in the cost per unit in generating, distributing, and general expenses. In consequence of the increase in the business of the Corporation, the directors have found it necessary to acquire additional property at Eccleston-place and Millbank-street. In dealing with the revenue of the past year, your directors have, after writing off bad debts, a portion of preliminary expenses, and placing £953 to credit of sinking fund, added a sum of £9,780 to the depreciation account. The net revenue of the year amounts to £23,731. 11s. 9d., out of which an interim dividend at the rate of 5 per cent. per annum for the half-year ending June 30, 1895, has been distributed. The Board now recommend the payment of a dividend at the rate of 9 per cent. per annum, less income tax, for the past half-year, making 7 per cent for the year ending December 31 last, carrying forward a balance of £1,338. 14s. 10d. The holders of founders' shares becoming entitled to a share of the surplus profits after payment of a dividend of 7 per cent., this balance will be carried forward as follows: ordinary shareholders' undivided profit account, £1,004. 1s. 2d. ; holders of founders' shares, £334. 13s. 8d. The premium of £8,000 received on the issue of new shares has been carried to the credit of the reserve fund, and invested. In

CUBA SUBMARINE TELEGRAPH COMPANY, LIMITED

The ordinary general meeting of this Company was held on Wednesday at Winchester House, E.C.

Mr. C. W. Parish presided, and moved the adoption of the report. The sum of £10,000 had been added to the reserve fund, and the directors, he said, recommended a dividend at the rate of 8 per cent. per annum, the balance of £3 719 being carried forward. In consequence of the insurrection in Cuba, which still continued, the Spanish Government had made certain proposals to the Company, which had resulted in the Company obtaining a concession to lay a cable between Cienfuegos, Casilda Tunas Jucaro, Santa Cruz, and Manzanillo, with a subsidy of £2,000 per annum from January 1, 1896 till August 27, 1910, which was the date when the original concession would expire. This cable had been successfully laid by the contractors and duly taken over by the Company.

The report was adopted.

NEWCASTLE AND DISTRICT ELECTRIC LIGHTING COMPANY, LIMITED.

Directors: John D. Milburn, Esq. (chairman), the Hon. C. A. Parsons (managing director), Sir B. C. Browne, Colonel W. M. Angus, Colonel H. S Dyer, John B. Simpson, Esq. Jas. Patterson secretary. W. D Hunter engineer.

Report of the directors submitted to the shareholders at the ninth ordinary general meeting held at the Station Hotel, Neville-street, Newcastle-upon-Tyne, on Tuesday, Feb. 11:

The directors have pleasure in again reporting that the supply of current continues to give satisfaction to the Company's consumers. The installations connected to the Company's mains during the year are equal to 3,200 10-c.p. lamps, bringing the total up to about 24,700, and 471 662 units of electrical energy have been supplied, as against 431,239 units supplied in 1894. During the past year 1 650 yards of main and branch piping have been laid, together with 3,771 yards of main and branch cable. The condensing plant continues to work satisfactorily, and your directors anticipate making other improvements with the object of still further reducing the cost of production. The gross earnings during the year amount to £4,302 9s. 11d., and after paying interest, and making provision for depreciation, and writing off the balance of formation expenses (£563), your directors are able to recommend a dividend at the rate of 4 per cent. for the half-year ending December 31 (less income tax), which, together with the interim dividend paid in July last, makes the dividend 6½ per cent. for the year. Sir B. C. Browne and Colonel H. S. Dyer retire by rotation, but are eligible, and offer themselves, for re election as directors. The auditors, Messrs, Strachan and Co., also offer themselves for re-election.

CONTRACTS FOR ELECTRICAL SUPPLIES

CONTRACTS OPEN.

Parma (Italy).—The municipal authorities of the city of Parma desire tenders by February 25 for the electric lighting of the city from June, 1897, to 1912.

Beziers.—Offers are wanted by February 15 for a concession for an electric tramway, about 8,800 metres (5½ miles) long. Particulars at the Mairie, Beziers, France.

Manuel.—Offers are wanted for the electric lighting of the town of Manuel, in the province of Valencia, Spain, for 15 years. Number of inhabitants, 1,500. Price suggested, 1,500 pesetas, payable monthly.

Belper.—The gas company are considering the setting up of an electric lighting plant, and electrical contractors can obtain information as to it on application to the Managing Director, Gas Company's Offices, Belper.

Teneriffe (Canary Islands).—Tenders are invited for the electric lighting of the town of Santa Cruz, Teneriffe, for a period of 35 years. Particulars can be obtained at the Ministerio de la Gobernacion, Madrid, and tenders must be delivered by February 29.

Brunn (Austria).—The Municipality desire offers for the construction and working of a central station for the supply of electric energy for lighting the town, for power, and if required, for running a tramway. Tenders must be sent before March 31 to the Bürgermeister, Brünn, Austria, from whom particulars can be obtained.

Sunderland.—The Town Council ask for tenders for two continuous current dynamos and engines, three Babcock and Wilcox boilers, an economiser, and water softening plant. Particulars can be obtained from the borough electrical engineer at the electrical supply station, Sunderland, upon depositing £1. 1s, and tenders must be in by March 13

Paris.—The French Telegraphic Department offer for tender on February 27 the supply of 125,000 kilogrammes of bronze or copper wire and on February 28 a telephone cable and materials for telephone batteries. Applications for permission to tender must be made to La Direction Générale de postes et des télégraphes by February 17 in the first case and February 18 in the second.

Eston.—The Eston Urban District Council invite schemes for lighting the district by electricity. Such schemes to embrace (*a*) plan and estimated cost, (*b*) annual working cost and maintenance. Plan of the district may be seen and particulars obtained of Mr. T. W. Stainthorpe, A.M.I.C.E., district surveyor, Grange-town, Yorkshire, to whom the plans, etc., must be sent by May 1.

Bridlington.—The Bridlington Urban District Council invite tenders for the lighting of the public streets and places within the district of the Council for one year, from March 31, 1896, in accordance with certain conditions which may be seen on application to the surveyor, Prospect-place. Tenders to be sent to Mr. Chas. Gray, clerk, Bridlington, marked "Tender for Lighting," by 17th inst.

Menston (Yorks).—Tenders are invited for the supply of telephones and electric bells for the new buildings and houses upon the estate, for the Committee of the West Riding Asylum, Menston. The specification may be seen at the county surveyor's offices, Wakefield, and at the clerk of works offices at the asylum. Tenders to be delivered to the office of Mr. J. Vickers Edwards, county surveyor, Wakefield, by 17th inst.

Keighley.—Tenders are invited for providing and fixing telephonic communication between the various buildings forming the infectious hospital now in course of erection at Morton Banks, near Keighley, for the Keighley and Bingley Joint Hospital Board. The buildings and plans can be inspected on application to Mr. Alfred Moore, clerk of the works at the hospital. Tenders, marked on the outside "Tender for Hospital Telephones," will be received by Mr. Geo. E. Spencer, clerk, North-street, Keighley, not later than noon on March 4.

Brussels.—The Belgian State Railways are offering for tender the work necessary for the alteration of the conductors and wiring for the electric lighting of the Marbehan Station. The contract is part of a rearrangement of the water supply, and particulars are obtainable at the Bureau du Chef du Service, Arlon, Rue de la Station, 26 Tenders must be in by February 20. Tenders are also required by February 19 for the supply of a large quantity (78 lots) of materials for the Belgian Telegraphs. Particulars can be obtained at the Brussels Bourse.

Islington (London).—The Vestry of St. Mary, Islington, invite tenders for electrical engineers' stores, etc. Forms of tender and further particulars may be obtained, and the draft contract inspected by application, between 10 a.m. and 12 noon, at the Vestry Hall, Upper-street, N. No tender will be received after 12 noon on 27th inst. Persons tendering must be prepared with a £10 note, to be deposited (not enclosed with the tender), as a guarantee of good faith until the execution of the contract. Those tendering for more than one of the items must enclose each tender in a separate cover, and be prepared to deposit a separate £10 note with each tender. Each cover must be properly endorsed.

RESULTS OF TENDERS.

Southport.—The Town Council have accepted the tender of Messrs. E. G. Pulford and Co. for fitting up a new telephone system at £397 10s.

Birkenhead.—The Corporation have accepted the tender of Messrs. Drake and Gorham, 66, Victoria-street, London, S.W., at £215, for the wiring of the town hall for electric lighting.

Maidenhead.—The following tenders were received for carrying out certain electric bellwork at the School for Technical Instruction: C Batting, Maidenhead, £8 15s.; Pearse, Maidenhead, £5. 15s.; Bloomfield, Maidenhead, £5. 10s. 6d. (accepted).

Shoreditch (London).—The following tenders have been received by the Shoreditch Vestry for the proposed electric lighting buildings (boiler-house and engine-room), at Pitfield-street, Hoxton:

Nightingale, Albert-embankment	£10 494	0	0
Manlove, Alliott, and Co, Limited, Nottingham	10 540	16	0
Shelbourne and Co, Fenchurch-street	10 005	5	9
Kirk and Randall, Woolwich	9,442	0	0
Jarvis and Sons, Hackney-road	9 926	0	0
Chessum and Sons, Haggerston	9,499	0	0
Wilkinson Bros., Finsbury Park	9,971	0	0
Coulsell Bros, Bethnal Green	9,383	0	0
Pattinson and Sons, Whitehall	8,854	0	0
Atherton and Dolman, Poplar (accepted)	8,535	0	0

Digitized by Google

Southport.—The following tenders have been received for the electric lighting and fittings to same at "Belle Vue," Southport, for Sir George A. Pilkington, J.P., and C.A. (Mr. C. Sydney Ingram, architect) Specification by the architect:

G. Hill and Co., Manchester	£345	3	0
Liverpool Electric Supply Company	340	0	0
Manchester Edison-Swan Company	304	11	6
Verity and Co., Manchester	293	6	0
Albert Maund, Southport (accepted)	283	0	0

St. Pancras (London).—Tenders for the wiring and other work in connection with the electric lighting of the Vestry Hall and offices in Pancras-road, for the St. Pancras Vestry, have been received as follows:

Maple and Co., Limited	£553	11	3
Roger Dawson, Limited	528	15	8
H. F. Joel and Co.	477	7	10
H. Binks and Co.	449	16	6

P. Jones	836	17	0
C. A. Hemingway	333	8	6
L. Alwyn	331	0	0
Laing, Wharton, and Down	304	6	6

The tenders were referred back to committee.

BUSINESS NOTES.

Prestwich.—The Urban Council have decided to issue circulars to ascertain the probable demand for electric light.

Hove.—The workrooms at the new laundry are fitted, like the baths, with electric light generated on the premises.

Hull.—Dr. Holden has tendered his resignation as chairman of the Electric Committee, on account of his health and professional work.

Budapest.—The Ungarische Elektricitäts-Gesellschaft report a profit balance of 615,476 gulden, and the Board recommend a dividend of 5½ per cent.

Kettering.—By 16 votes to 4 the Board of Guardians decided that the telephone at the workhouse should be connected with the National Telephone Company's exchange.

Grimsby.—The Town Council's provisional order for electric lighting expires next April; Mr. Barrett has therefore given notice to bring the matter before the next meeting.

Electric Lighting of Railway Carriages.—The Great North of Scotland Railway Company are having their carriages fitted with the electric light apparatus invented by Mr. Arthur B Gill.

Morley.—At the Town Council meeting, a letter from the Tradesmen's Association on the lighting of Queen street and the business premises in that street with electricity, was referred to the Gas Lighting and Electric Lighting Committee for consideration.

Hackney (London).—The Vestry have adopted a scheme of electric lighting in combination with a dust destructor. The capital outlay will be £80,000, but it is estimated that the parish will reap a profit.

Renfrew.—The Town Council are taking steps to light the burgh. The terms asked by the Paisley Council are too heavy, but the latter body has decided to hold a special meeting to consider the matter.

Walsall.—The Electric Lighting Committee have reported that during the month the total number of customers supplied was 45, the number of units consumed during the month being 5,230, and the income therefrom £130. 15s.

Liverpool Overhead Railway.—The traffic receipts of this railway for the week ending February 9 amounted to £1,090, as compared with £859 in the corresponding week of the previous year, being an increase of £231.

Morecambe.—An agreement for the purchase of the Morecambe Electric Light and Power Company's undertaking and plant for £3,897 has been executed, and the chairman of the District Council has been empowered to convene a public meeting to ratify the same.

Telegraph Construction and Maintenance Company, Limited. The directors have decided, subject to the audit of the accounts, to pay a dividend of 10 per cent., or £1. 4s., per share, in addition to the 5 per cent. already paid, making 15 per cent. for the whole of 1895.

Horfield.—At the meeting of the Urban Council, Mr. A. G. Stennard moved that a committee be formed to take into consideration the best means of lighting the district with electricity. Mr. W. Maggs seconded. The resolution was carried, and a committee was formed.

Fort William.—The ceremony of cutting the first sod of the lade which is to supply the water for generating electricity to light the burgh of Fort William was performed on Tuesday afternoon in a field on the banks of the River Krachnish, about three miles from Fort William.

Bradford.—The Gas and Electricity Supply Committee of the Corporation have received permission from the Finance Committee to present an application to the Local Government Board for power to borrow the sum of £40,000 required for the extension of the electricity works.

Darlington.—Serious complaint having been made in the east end of the town owing to the erection of telephone poles on the main roads, in some cases close in front of shops and houses, the matter was referred to at the Town Council meeting and referred to the Streets Committee.

Halstead.—At a meeting of the District Council, the surveyor read a report of the committee recommending that Messrs. Crompton and Co., of Chelmsford, be asked to send down an engineer to report as to the lighting of the town by electricity, at a charge of 10 guineas. This was agreed to.

Kirkby Lonsdale.—At the meeting of the Urban Council a letter was read from Mr. Harris stating that he intended to carry a wire from the old corn mill in Mill Brow to Lunefield, and asked if the Council would make any objection. The Council granted permission, providing it was placed at the proper height.

Macroom (Cork).—For some time past electrical engineers have been at work on the premises of Messrs Baldwin and Co, Limited, Macroom, for the purpose of lighting up the premises with electric light. Several shopkeepers in the town have signified their intention of introducing the light into their shops and premises.

Cambridge.—The contract for public lighting expires in May next, and the clerk was asked at the Urban Council meeting whether the Cambridge Electric Lighting Company had power to light Chesterton, or, if not, could the Council confer power? The Clerk said he could not answer the question without reference.

Mason College Chemical Society.—At the meeting of this society at Birmingham, Prof. Percy Frankland in the chair, Dr. T. S. Patterson read a paper entitled "The Electrolytic Dissociation Theory in its Relation to Analytical Chemistry." A discussion followed, in which Dr. Boyd, Dr. Baker, and Mr. Macgregor took part.

Harrogate.—The electric lighting cable has been laid. The electric lighting plant will be located on the irrigation farm, which is the property of the Corporation, and the motive power will be derived chiefly from refuse destructors, which are intended to be erected, and by this means considerable economy of fuel will result.

City and South London Railway.—The returns for the week ended February 9 were £972, compared with £1,022 for the corresponding period of last year, being a decrease of £50. The total receipts for the half-year terminating as above were £5,997, compared with £6,041 in the same period of the preceding year, being a decrease of £44.

Bedford.—The Corporation have decided to borrow a further instalment of £12,500 (on account of the loan of £27,000 already sanctioned) for carrying out the following scheme—for public lighting only, £1,000; private lighting in specified streets, £8 750; machinery at central station, £2,500; contingencies, £250—estimated cost, £12,500.

Keswick.—Application has been made to the Board of Trade for an electric lighting provisional order by the Urban District Council, and the Keswick Electric Lighting Company, Limited, ask for similar powers, including in their scheme the supply of electricity to St. John's, Castlerigg, and Wythburn-under-Skiddaw and Above Derwent.

Newport (Salop).—At a meeting of the Council Councilor Smith presented a petition asking the Council to consider the advisability of using electric light in the district. Councillor Boughey opposed it—first, because the question had been considered and decided against, and, secondly, because the Council had the great matter of sewerage before them.

South Staffordshire Tramways Company, Limited.—The action brought by this Company against Messrs. Ebbsmith and Wain to recover alleged secret profits, and for the rescission of contracts made while the defendant Wain was manager of the Company, was commenced before the Lord Chief Justice and a special jury in the Queen's Bench on Wednesday.

Garston.—At the Urban Council meeting a memorial was submitted from residents in the districts asking the Council to support the application of the Liverpool and District Lighting Company for powers to supply electricity in the district. The law clerk was instructed to consult with the law clerks of the Much Woolton and Allerton District Councils upon the question.

Telegraph Extension.—Lord Balfour of Burleigh has informed a deputation which waited on him from the Ross-shire County Council that he had been in communication with a representative of the Treasury on the subject, and he hoped the result might be that not only would they have a small sum for expenditure upon roads this year, but also a small sum for the further extension of telegraphs.

Digitized by Google

The "Dover."—This new paddle-steamer, built for the London, Chatham, and Dover Company for the Dover and Calais route, is lighted throughout by electricity on the Edison-Swan system, the plant and fittings being supplied by that company, and fitted by the shipbuilder's electrical department. Besides the internal lights, there are four large embarkation lamps.

Loughborough.—The borough surveyor has made a further report as to the installation of the electric light at the sewage-disposal works, in which he recommends that a C2 friction driving plant which the Brush Company offered to sell to the Corporation for £100 be acquired, instead of the dynamo and engine which it was decided to purchase at the last meeting, so that a larger output might be obtained. The Town Council have adopted the recommendation.

Redcar.—It is reported that the lighting of the town by electricity, about which so much was said a few months ago, is not likely now to be carried out, as Mr. Stacey, of Sheffield, the engineer who proposed to undertake the work, has abandoned his scheme because of the very poor support he had received from the Redcar people in his endeavour to float a company to carry out the business.

Dover.—The town clerk, as requested, reported to the Town Council that there were 21 electric lamps on the sea-front and up to the Market-place, and which had cost £630. Extra arc lamps were agreed to be supplied at £30 per year per lamp. Already there were 10 extra lamps in Snargate street at a cost of £300 per year. The question of improving the form of lamp-post was referred to the Lighting Committees.

Bath.—It is intended to light the G.W.R. station by electricity, and the company are about to erect a building to receive the necessary apparatus. Mr. Gatehouse having reported to the Council that during the fortnight 13 lamps had been out, but the lighting on the whole had been steady, Mr. Phillips remarked that during the last two or three days it had been anything but steady—it had been very "groggy."

Bristol.—Since the opening of the electric tramway a number of deputations from various corporations in the kingdom have visited the city for the purpose of inspecting the line. In the report of the Bristol Tramways Company for the half year ending December 31, reference is made to the opening of the electric tramway between Bristol and Kingswood, and it is stated that the working has proved very satisfactory.

Cardiff.—On the western side of the new exhibition, buildings are now being erected to contain the electric lighting engines and dynamos, as well as the boilers for motive power for the various purposes of the exhibition. The machinery section will be located in a building about 260ft. in length by 80ft. in width, whilst the mines, mining, and horticultural sections will find a home in a somewhat similar-sized building adjoining.

Fowler-Waring Cables.—The new Company has been registered, with a capital of £200,000 in £5 shares, to acquire as a going concern the business of the Fowler-Waring Cables Company, Limited (incorporated in 1889), together with all the property, assets, and liabilities. The first directors are Messrs. W. Fowler, W. Chamberlain, G. Fleming, Lord Medway, and Mr. G. F. Smart. The registered office is 32, Victoria-street, S.W.

Colchester.—The Town Council have appointed an Electric Lighting Committee and have engaged Mr. Massey, as consulting electrical engineer, to prepare a statement of the general outlines of a scheme, and to consider, report, and advise upon schemes and tenders, based upon such outlines, to be obtained by the Council from four firms of electrical engineers for lighting a definite area and for superintending the construction of the works.

Blackburn.—The Gas Committee's minutes, which have been passed by the Town Council, stated that the town clerk had reported that the Hopkinson patent rights in respect of the three-wire system would expire this year, and that the patentee was applying for a renewal of the patent. It has been resolved that it be an instruction to the town clerk, if the Corporation have a *locus standi*, to oppose the renewal of the patent rights.

Lincoln.—The Special (Electricity) Committee have met and considered the resolution of the Council appointing it and the letters and reports on the subject of electric lighting from various bodies and persons. Each member of the committee was requested to obtain as much information as possible as to the mode in which existing electrical works are constructed, so that further material might be placed before the committee at a future meeting.

Kidderminster.—Alderman Parry moved certain formal resolutions at the Town Council meeting relative to the action of the Council with regard to the proposed electric tramway between Kidderminster and Stourport. He pointed out that it was not intended to offer any opposition to the company's Bill in Parliament if the conditions agreed to by the company with the Council were adhered to, but the object of the resolutions was to give the Council a *locus standi* to oppose the Bill if necessary. The resolutions were carried.

Catalogue.—We have received a copy of Messrs H. M. Salmony and Co.'s illustrated 1896 catalogue. The company's electrical engineering works are at Notting Hill, W., and the offices at 61, Charing Cross-road. In consequence of the great demand for their instruments and accessories, the firm have been compelled to transfer the manufacture of accessories to separate works at Cheapside, Birmingham, where they have laid down plant of an extensive character.

City of London Electric Lighting Company.—The directors of the City of London Electric Lighting Company, Limited, have decided to recommend the payment of a dividend, subject to the completion of the audit, of 6s. per share on the preference shares for the second half of 1895, making, with the interim dividend already paid, a total distribution of 6 per cent. for the whole year; and of 10s. per share on the ordinary shares for the 12 months, being at the rate of 5 per cent. per annum. The transfer books and registers will be closed to 21st inst. inclusive.

Huddersfield.—The town clerk (Mr. F. C. Lloyd) has read a communication to the Electric Lighting Committee which he had received from the Local Government Board sanctioning an application of the Corporation for power to borrow £50,000 for the purpose of extending the electric lighting works and plant of the Corporation the amount to be repaid in 25 years. The previous loans on electric lighting account amount to £50,000, of which £12,000 is to be repaid in 30 years and £38,000 in 15 years.

Newcastle-on-Tyne.—At the last meeting of the City Council the Mayor moved that the Council petition Parliament to insert in the Bill regarding the tramways an additional power enabling them to work any or all the tramlines by electricity. The petition was adopted, as was a motion asking to have the time specified for the completion of the lines extended from three to five years. A deputation of members of the City Council has visited Edinburgh for the purpose of obtaining information with regard to the cable system of tramways.

Edinburgh. - On the representation of the chief constable, the Plans and Works Committee have recommended the installation of the electric light in the police cells at a probable cost of £180. The Town Council, at a special meeting, have resolved to join the Corporations of Edinburgh, Glasgow, and Belfast in opposing an application by the Westinghouse Electric Company for an extension of their three-wire patent. If the patent is extended the annual charge to Aberdeen, in which there are already 100 tons of the wire laid, would be £250.

Croydon.—The Electric Lighting Sub-Committee have reported that the chairman submitted a plan showing the proposed method of public lighting in the compulsory area. This plan provides for the erection of arc lamps in Katharine-street, Park-lane, Mint-walk, from Scarbrook-hill to West Croydon Station, Poplar-walk, Station-road, St. Michael's-road, part of Wellesley-road, George-street, Church street, and from Crown-hill to Pitlake. The estimated extra cost of these lights over the price now paid for gas lamps in the above area is from £300 to £400 per annum. The matter is being further considered.

Worcester.—At the meeting of the City Council, Alderman Williamson moved a recommendation of the Electricity Committee that the Council should make application to the Local Government Board to sanction a further loan of £5 000 for electricity purposes, for the purpose of defraying the expenditure incurred and now being incurred under the following heads, and to be repayable in 30 years—namely, generating station, £450; generating plant, £1,000; distributing and other plant, £920; extensions of mains, £2 520; street-lighting, £110. The motion was carried.

Douglas (Isle of Man).—Operations have been commenced on the undertaking which will add another electric tramway to the transport system of the island. This is called the Douglas Head Electric Tramway, and it is being carried out under the superintendence of Mr. W. L. Fletcher as resident engineer. In the common-law division of the Manx High Court, the action of George Crellin against the Isle of Man Tramways and Electric Power Company to recover damages for injuries sustained while travelling as a passenger on the company's electric car system, is stated to be settled. It is understood plaintiff is to receive £250 and costs.

Bradford.—The Gas and Electric Supply Committee request the Town Council to authorise the presentation of a memorial to the Local Government Board for power to borrow the sum of £40,000 required for the extension of the electricity works consequent upon the increasing demands for supply of electricity. The committee also recommend the acceptance of the tender of Messrs. Siemens Bros. and Co., Limited, for the supply of two dynamos required at the proposed new electricity works in Valley-road for £2,650, and the tender of Messrs. Willans and Robinson, Limited, for the supply of two 600 i.h.p. steam-engines required at the same works for £4,400.

South Staffordshire Tramways.—At a meeting of the West Bromwich Town Council the Highway Committee reported that up to the present they had not received any new proposal from the tramway company as to a new method of traction, but they were prepared to consider any scheme that might be submitted. Mr. Lawley remarked that he believed there was likely to be more competition for a cable tramway. One or two firms were prepared to lay down a good service, and it was their duty to see that they got the best system. He had seen the plans prepared by electrical engineers in Birmingham for a complete system, embracing the latest improvements.

Ambleside.—The Windermere and District Electricity Supply Company, Limited, seek power to produce store, and supply electricity, etc., within the district of the Urban District Council. At a meeting of the Council the report of the Electric Lighting Committee was read, and Mr. Huddlestone explained that the result of the committee meeting was that they were forced into making application for a provisional order. The Council would not be bound to take it up for two years. The Chairman remarked that the Council would not be bound at the end of that time to have their own electric works. The members being of opinion that the committee had done the best they could, the report was adopted.

Altrincham.—At a meeting of the Urban Council it was resolved to go into committee on the question of electric lighting at

Digitized by Google

Ashton-on-Mersey and Timperley. The clerk (Mr. Stokoe) laid before the Council a proposition from the Altrincham Electric Supply, Limited, for the lighting of these districts. The matter was then considered, and it was resolved, "That the clerk be instructed to inform the Board of Trade of the agreement between the Electric Supply Limited, and the local authorities now in existence for the purchase of the present works, and to ask that such clauses may be inserted in the proposed order as will protect this Council in the event of their deciding to purchase under the said agreement."

Tape Prices.—In the case of Cochrane *v.* the Exchange Telegraph Company, in which the plaintiff sued the company for default in supplying tape prices of Stock Exchange quotations, Mr. Justice Chitty has found that with regard to two instruments they were held on contracts which could be determined on reasonable notice, which he held under the circumstances to be three months' notice, and in respect to these the plaintiff was entitled to damages for breach of contract, which he assessed at £50, but not to an injunction. As to the third instrument, it was held under a contract which made its use subject to conditions imposed by the Stock Exchange, and the plaintiff had no cause of action. No costs were given to either side.

Wolverhampton.—The directors of the Electric Construction Company, Limited, have commenced additions to their large depôt situated at Bushbury, near Wolverhampton, from plans and specifications prepared by Mr. A B. Blackburn, civil engineer. The office arrangements have already been extended, and employment is now given to upwards of 600 hands. The site of the operations now going on adjoins the west side of the present main shopping, at the junction of the Stafford-road and Showell-road, and comprises over an acre of land at the rear of Gorsebrook House, Gorsebrook The total cost of the extensions and alterations, including the extra tools and machines, is estimated at £10,000, which the directors are prepared to vote forthwith.

Clacton-on-Sea.—At the Urban District Council meeting, Mr. Murray moved a resolution that an advertisement be inserted in the electrical papers to the effect that the Council were open to receive estimates of the cost of plant, etc., for the installation of electric light in the town. He thought it was only right to go in for the best light possible The new electric light would be from 2½d. to 3d. per Board of Trade unit, which would be about the same as gas at 5s. per thousand. The prime installation he estimated at from £10,000 to £12,000. Mr. Revell seconded. An amendment that it be referred to the Lighting Committee for enquiry and report was moved by Mr. Baker and seconded by Mr. Schulkins. The amendment was carried, eight voting in favour and two against.

Greasborough.—At the meeting of the Urban District Council it was stated that Messrs. Young, Wilson, and Co., Sheffield, the solicitors to the promoters of the Sheffield District and Rotherham Tramways, had written to the clerk, Mr. Edward Jackson, as under: "We regret to inform you that owing to the action of the Sheffield Corporation, and to the difficulties which have arisen in connection with that portion of our clients' tramways scheme which extended from the city boundary to Rawmarsh, our clients have been reluctantly compelled to withdraw their scheme for the present session. In doing so, they desire us to thank your Board and yourself for the courtesy which you have extended to them during the negotiations which have taken place with reference to the project."

Hammersmith (London).—The Electric Lighting Committee reported at the Vestry meeting that they were in possession of the necessary information as to the space required for the generating station in Fulham Palace-road, and, having been advised that it is important to prepare for the erection of the buildings as soon as possible, they instructed the surveyor to invite tenders for the excavation and carting away of the soil. For the carrying out of this work the tender of a Mr. Greenham was accepted, and the committee recommended that the surveyor be instructed to prepare the necessary plans for the buildings. Mr. Glasier objected to the recommendation on the ground that the surveyor had already sufficient to do. Mr. Payne expressed a similar view, contending that the work should be carried out by the usual professional men. After some further discussion the recommendation was agreed to.

Glasgow.—The sub-committee on electric lighting have submitted a report on their recent visit to Edinburgh. After describing the chief features of the Edinburgh installation, and pointing out wherein they differ from those of Glasgow, the committee conclude by stating that, as the result of their inspection, they found that the street-lighting of Edinburgh is much better than the street-lighting in Glasgow, and that that result had been obtained by a more judicious employment of the light. They ask that the matter be remitted back to them to consider and report as to what measures are necessary to improve the present system of the electric lighting of the streets of the city, with power to confer with the Electric Lighting Committee of the Corporation. The committee on the electric lighting of the city suggest that the electric light and gas departments should be separated. This has been agreed to.

Reading.—The secretary of the Reading Electric Supply Company having written that the mains were now laid in the various streets forming the centre of the town, the Town Council have resolved to ask for particulars of the cost of supplying the current to the public lamps in the area referred to. The following motion was proposed by Mr. Simmons, according to notice: "That the Highways and Lighting Committee, or a sub-committee to be appointed by them, be requested to confer with the Reading Tramways Company, Limited, with a view to ensuring an immediate improvement of the tramways and the mode of working the same." He was under the impression that if the company were approached they would be inclined to spend £40,000 or £50,000 in extending the lines to Whitley and Caversham, and in improving them, and would perhaps adopt electric cars, and they might do the improvements better than the Corporation. The resolution was lost.

Neston.—The electric light question has caused one member (Mr Grenfell) of the Urban Council to send in his resignation. Mr Grenfell had suggested that they should adopt the electric light and it was proposed that the sub-committee should be empowered to spend 20 guineas for the purpose of enabling them to secure an engineer to draw out a plan of the district, and to prepare estimates, but the sub-committee never went any further. Mr. Jamieson said only about 60 ratepayers had expressed themselves in favour of taking the light, and therefore it would have been madness for the sub-committee to go on with the scheme In their report they stated that if the Council were not satisfied with the financial aspect of the matter they should drop it. It had dropped for the present, but it would be revived again. He could not see how the sub-committee were to blame in the matter It was eventually decided by a unanimous vote to ask Mr. Grenfell to reconsider his decision.

Blackpool.—The following are the minutes of the Electric Lighting Committee which came up for confirmation at the Town Council meeting: January 25.—Resolved, that consequent upon the resolution of the Council on January 7, 1896 as to alterations of discounts on supply of electrical energy, the town clerk be instructed to give due notice to the Blackpool Winter Gardens and Pavilion Company, Limited, to cancel the existing agreement as to supply of electrical energy, and that the town clerk be requested to communicate with the company thereon as now directed. Read letters of December 18 and 30, 1895, from Messrs. Dean and Waterhouse as to the supply of electrical energy to premises occupied by Mr. John Taylor. Resolved, that the consideration of such letters be deferred until the next monthly meeting. The borough electrical engineer reported that he had visited Leeds, as instructed by the committee on January 14, 1896, and inspected a new vertical 300-kilowatt engine, running at the works of Messrs. Fowler and Co., Leeds.

Tunbridge Wells.—The report of the Lighting Committee, which was read at the Town Council meeting, and the adoption of which was moved by Councillor Wood, set forth the continued progress of the electric lighting system. Councillors Jenkinson, Strange, Penn, and Gower instanced parts of the town where more light was needed, such as St. James's-road, Beulah-road, Albion-road, etc, and the committee promised to consider the suggestions as to the side streets and suburbs. Councillor Strange raised objections to certain Corporation information on electric lighting questions getting into newspapers long before such matters came before the Lighting Committee. He asked who supplied this premature information. Did any members of the committee give this information? If so, this could not be right. Councillor Wood, as the chairman, and other members of the committee, disclaimed all knowledge of how the information appeared in the Press, and the subject dropped. The Corporation have decided to raise £25,000 for electric lighting purposes.

Newport (Mon.).—At the meeting of the County Council the Electricity Committee reported in favour of seven suburban roads being included in the extension of the electric system, but with reference to the purchase of meters they thought it desirable these should remain the property of the Corporation. Mr. Morgan wanted to know when Maindee was to have the light, and Alderman Moses replied that the committee would be prepared to extend the mains to Maindee as soon as there was a demand made for a supply. Mr. Proctor Eeles said he saw by the estimate for the ensuing six months that the income from the electric light was estimated at £1,000 and the outlay at £1,805. That involved a loss of £1,600 per annum to the ratepayers, and he wished to know when the chairman anticipated the light would be worked with some profit. Alderman Moses said that most new undertakings were for some time non-paying. The undertaking was now paying its way better than before, because the consumption was increasing. The report was afterwards adopted.

New Company.—The Cox Thermo-Electric Company, Limited, has been registered with a capital of £100,000 in £10 shares. The objects are stated to be to acquire any patents, patent rights, licenses, concessions, and the like, and in particular any inventions relating in any way to the direct generation of electricity from heat by means of thermopiles, or thermo-electric generators, or to the construction, maintenance, improvement, or working of thermopiles or thermo-electric generators of any kind; with a view to the above objects to adopt and carry into effect the agreement referred to in Clause 3 of the company's articles of association expressed to be made between H. B. Cox, R. W. Wallace, and F. J. Webster of the one part, and this company of the other part; and generally to carry on business as manufacturers of and dealers in thermopiles and thermo electric generators; as mechanical engineers, dynamo builders, builders of cars, vans, carriages, and vehicles of every description; as suppliers of electricity; as manufacturers of and dealers in all kinds of electrical appliances; and as metal founders.

Bromley.—At the meeting of the Urban District Council the Standing Orders Committee reported that, in accordance with the reference of the Council made on November 26, they had received a deputation from the committee represented by Messrs. Waterer and Dickins in reference to the acquisition of the electric lighting

Digitized by Google

provisional order. As a result of such meeting, Messrs. Waterer and Dickins submitted a formal enquiry as to whether the Council would be disposed to hand over its powers and interests in the provisional order, provided the corporation which must be formed were willing to agree as to any reasonable conditions as to providing public lighting, and giving the Council the option to purchase the undertaking at any period within seven or 14 years at a price to be fixed by arbitration, or in some other way agreeable to the Council. The committee recommended that a reply be sent that the Council would only be prepared to hand over the provisional order to an approved local corporation on the undertaking to pay the cost of and incidental to obtaining that order. The report was adopted.

Chesterfield.—At the meeting of the Town Council the Mayor moved: "That the resolution passed by the General Purposes Committee on January 15, 1894, and confirmed by the Council on February 13, 1894, by which the National Telephone Company were to be charged 7s. 6d. per pole for each telephone pole standing in either the streets or public thoroughfares in the borough or on Corporation property be rescinded." The motion was seconded. Alderman Wood opposed, in favour of the original proposition. The time was probably not far distant when the town would be lit by electricity, and if they allowed that private trading company to put their wires indiscriminately along their main thoroughfares they might depend that the company as a money speculation would so arrange their wires that it would be impossible for the Corporation or anyone else undertaking to light the town with electricity to put up their wires unless they first paid out the company's rights. The resolution was carried by 13 to 5, and it was decided that in future the payment be 1s. per pole per year.

Dungannon.—At a meeting of the Town Commissioners, the following resolution was unanimously adopted: "That, having read the communication of this date from Mr. C. M. Wilson, intimating his intention to apply to the Board of Trade for an order, *inter alia*, authorising him, or such other persons as may be associated with him, to promote, undertake, and establish works for the supply of sufficient electrical energy under and in pursuance of the provisions of the Electric Lighting Acts, 1882 and 1888, for the public lighting of Dungannon, and for private purposes, and asking us to approve of and sanction the project, do hereby accord same, believing that the adoption of the scheme will lead to considerable reduction in taxation for the lighting of the town, and will be of material advantage to private persons using artificial light not merely in the reduction of expenses, but also in the better promotion and protection of employés in factories, workshops, and shops; and we authorise all necessary consents to be given to him in furthering and promoting the undertaking, subject to the compliance with the regulations and conditions of the Board of Trade for securing the safety of the public."

Wakefield.—The minutes of the General Purposes Committee, read at the School Board meeting, contained a recommendation that Mr. Robert Hammond, consulting electrical engineer, of London, be appointed to advise the Board as to the lighting of the Ings-road School by electricity on the terms stated in his letter of December 4, 1895. Archdeacon Donne proposed and the Rev. H. G. Parrish seconded their adoption. Mr. Stephenson moved as an amendment that the minute referred to be sent back to the committee. The Chairman: For the reasons you have given in committee, I suppose? Mr. Stephenson: Yes, and some others. The mover and seconder of the resolution adopted Mr. Stephenson's proposal, and the minute was referred back. At a later stage of the meeting the following item, which appeared on the agenda, was submitted to the meeting: "To consider a recommendation from the General Purposes Committee that Mr. Robert Hammond be appointed to advise the Board as to the lighting of Ings-road School by electricity, at a fee of £5 per cent. upon the cost of the installation, with a minimum fee of 25 guineas, such fee to include drawing complete specification, adjudicating upon tenders, inspecting material supplied, inspecting work during progress, making final tests, and passing installation." Mr. Stephenson desired that this should also be referred back, and it was agreed to.

Stafford.—At the meeting of the County Council the Finance Committee reported: "That, if the cost will not exceed £200, it is desirable that electric wiring and fittings be provided for the Judges' House; that the Council be recommended to order the county treasurer to provide sums not exceeding £900 (according to estimate of county surveyor) for electric wiring and fittings, and for painting and papering and repairs throughout the Judges' House, and for necessary renewals of and additions to the furniture and household effects therein; that the Finance Sub-Committee be empowered to agree with the Stafford Corporation upon the basis and rate of charges for electric lighting; and that Mr. Bagnall be added to the sub-committee for that purpose, and that Mr. A. S. Bolton be requested to assist the sub-committee in considering the matter." Alderman W. H. Peach, in moving the adoption of the report, said that with regard to the electric light, he was glad to be able to say all the consumers were perfectly satisfied with the light and the charges which had been made for the current. The accounts sent out for the 11 weeks during which the current had been supplied amounted to about £250. It was now confidently anticipated that the concern would be able to pay its way, and not be a charge on the rates. He believed that theirs had been an unique electrical experience in that since the current had been turned on they had never had any hitch whatever.

Eccles.—The report of the Electric Lighting Committee presented at the Town Council meeting contained the following passage: "That the Council be recommended to defer the acceptance of any tender for the carrying out of the electric lighting works until after a Local Government Board enquiry has been held, and that to bring about such an enquiry the Council be recommended to make application to the Local Government Board for power to borrow the sum of £20,000 for the purpose of carrying out a scheme of electric lighting in the borough. The committee felt that by adopting this course the Council would at no further expense to the borough be able to ascertain what weight of opposition there is (if any) to the scheme after the issue of the electric light pamphlet, and also would be given this further advantage, that if it should be found in consequence of the opposition the Local Government Board decline to sanction the borrowing, the Board of Trade might with some reasonableness be asked to extend the Eccles order until such time as the Local Government Board put the Council in a position to proceed. If, on the other hand the borrowing powers were granted, the Council could then before expending any money reconsider the whole position, and take such course as they might deem advisable in the light of the information obtained at the enquiry." Alderman Kendal moved the adoption of the committee's recommendations which were as follow: "(*a*) That the electric lighting be proceeded with; (*b*) that a tender be accepted subject to borrowing powers being obtained; (*c*) that application be made for borrowing powers." The report was adopted.

Plymouth.—The Borough Council is considering whether it is advisable to supply electricity for lighting and for tramway traction; and whether, in connection with the central supply station, a refuse destructor can be advantageously used for raising steam. Mr. W. H. Preece, C.E., who has been consulted with reference to the proposed destructor, says that, although he has had no practical experience of a destructor, he has, on consideration, arrived at the conclusion that it may act as a steam raiser, and will certainly act as a feed-water heater. On economical grounds he fully supports the principle of combining the destructor with the generating station. Dr. Fleming, the expert whom the Corporation consulted, has considerable doubts as to the utility of the destructor as part of an electric lighting scheme, and advised the Corporation to make the electric lighting station at first entirely independent of the destructor. With reference to electric traction for tramways, Mr. Preece says there can be no question of its practicability, "neither can there be any question of its economy if the energy can be supplied in the power-house at 1½d. per unit delivered." The proviso is not unimportant. One unit of electric current represents, says Mr. Preece, just the power required to propel a car at the maximum speed allowed for one mile Dr. Fleming says that the average working cost of electric tramways is about 5½d. per car mile, as against 10d. for horse traction. At the Council meeting it was reported that in the minutes of the Municipal Offices Committee was a list of duties and terms of appointment relating to the office of electrical engineer to the Corporation, which stipulated the salary to commence at £300, to rise to £400.

Aberdeen.—The Gas and Electric Lighting Committee have reported to the Town Council that the gas treasurer had submitted to them a statement of the income and expenditure in connection with the electric lighting undertaking for the year ending December 31 last, from which it appeared that the balance, being profit for the year, amounted to £435. 0s. 9d. The committee recommend that this balance should be carried to and form the nucleus of a reserve fund; that the price of current for the present year be reduced and fixed at 5d. per Board of Trade unit; that the charge for meter rents be reduced and fixed as follows—viz., 12 amperes, 2s 6d; 25 amperes, 3s; 50 amperes, 3s. 9d.; 100 amperes, 5s.; 200 amperes 7s. 6d; 500 amperes, 15s. per quarter; and that the reduction on the price of current should not apply to public lighting or motors. Mr. Brown, manager of the Aberdeen district, has stated that during last year 173 new telephone lines were opened. The calls made by subscribers numbered 48,814 per week, or an average of eight calls per subscriber per day. The total length of the wires is 999 miles, there are 1,350 instruments, and the exchange lines are 100. A new switchboard, which will greatly facilitate the speed with which the wires can be connected, had been introduced, at a cost of £1,300. Aberdeen centre had been one of the most prosperous in the country. The Docks and Pilotage Sub-Committee of the Harbour Board have considered the remit as to the provision of an electric light installation for the quays. After discussion, it was resolved to request Mr. Nicol, harbour engineer, to make enquiry and report concerning harbour trusts in the south who have installations of their own, and the arrangements under which these are conducted.

Brighton.—The erection of the standards and the other necessary work in connection with the electric lighting of the streets in accordance with instructions already given by the Town Council is proceeding steadily. The original recommendation of the committee was for the erection of 120 arc lamps for the illumination of the Queen's-road, West-street, North-street, Western-road, St. James's street, Marine parade, the Steine valley, taking the route north by the London-road, and of these 80 are already in use, and it is expected that all will be complete by the end of the month. Since that recommendation was agreed to, however, the scheme has been greatly extended to take in New-road, Church-street, the Grand-parade, the east side of St. Peter's enclosure, Regency-square, and other thoroughfares, all to be lighted on the arc system, bringing the total of arc lamps to be erected up to 265; and, in addition, subject to the result of a Local Government Board enquiry, which has yet to be held, the Council have issued instructions for all streets in which the electricity mains are laid to be lighted on the incandescent system as in St. James's-avenue. These recommendations provide for the lighting of 20 miles of streets, and it is contemplated to make a

Digitized by Google

further extension so as to include Lewes road, Bristol-road, and St. George's-road, the only omnibus routes not at present taken in hand. The undertaking has by no means reached the limit of the local resources. As many as 29 new applications were received in January, as against 18 in the previous January; 12 in January, 1894; and five in January, 1893.

St. Pancras (London).—The Electricity Committee of the St. Pancras Vestry having advertised for tenders for wiring the vestry hall and offices, reported recommending that the Vestry should accept the tender of Messrs. Laing, Wharton, and Down, of 17, Gracechurch-street, E.C., for £304. 6s. 6d. A discussion, however, ensued, which showed that the Vestry had had no instructions to advertise for tenders, and it was ultimately decided to refer the matter back to the committee for consideration and report, "as the expenditure involved was very heavy." The Vestry have agreed to regulations for the information of electrical contractors carrying out work within the Vestry's area. These regulations—consisting of 48 items—include one framed in view of the late explosions, which prescribes that "no metal framework of any fittings shall be used as part of the electric circuit, or be in contact therewith, and no connection with gas or water pipes or 'earth' allowed." It is further stipulated that "combination gas and electricity fittings must not be employed, except by the special consent of the engineer, and under such precautions and conditions as he may direct." The Vestry undertake to inspect and test completed wirings free of charge, but all subsequent tests, if necessary must be paid for at 10s. each. "Should the insulation at any time fall below the standard specified, the Vestry may, after due notice, discontinue the supply of electricity to the premises." Storage batteries can only be constructed with the sanction of the engineer. The Vestry do not undertake any responsibility for the proper execution of any work on consumers' premises, nor for any loss or damage which may be occasioned by fire, or any accident arising from the wires, fittings, or other apparatus within the buildings.

Bangor (North Wales).—At a meeting of the Town Council, it was reported that the engineer (Mr. Medhurst) had submitted drawings of a central station, etc., to the Electric Light Committee. These had been referred to a sub-committee, consisting of the chairman (Dr. H. Grey Edwards) and Messrs. P. S. Gregory and Richard Davies. Dr. Grey Edwards wished to draw attention to some interesting facts. The returns for 1895 were beginning to come in, and so far they were very satisfactory. In Aberdeen, where the electric light had been in operation for the second year, the capital had been increased by £9,800. The number of lamps had been increased from 9,067 to 16,091. A profit of £435 remained towards the reduction of the rates. The price of consumption was 2·36d., while the price obtained was 5·99d. In Leeds, where the light had also been in operation for the second year, the capital had been increased by £20,000. The lamps had increased in number from 21,720 to 32,539. Five per cent. had been distributed and £3.300 had been placed to the reserve fund which was equal to another 5 per cent. on the capital. The price of consumption at the latter town was 2·05d., and the price obtained 4·91d. He regretted that a memorial had been sent from Bangor to the Board of Trade protesting against the introduction of the electric light. He failed to see the object of the memorial; it would certainly increase the expense of obtaining a provisional order. Mr. Thomas Lewis explained that it was the unanimous wish of the ratepayers at more than one meeting that a number of gentlemen should take steps in the matter. He and others considered they had done quite right by taking the course they had, because they felt strongly upon the matter, and no doubt those who held opposite views felt equally as strong. Dr. Langford Jones pointed out that there were 13 elected councillors in favour of the electric light and only four against it.

Halifax.—A special meeting of the Town Council has been held to consider the tramways question. Alderman Booth submitted the following resolution: "That this Council do assent to the promotion of the Halifax and District Tramways Bill, subject to the terms and conditions contained in a letter dated January 31, 1896, received by the town clerk's parliamentary agents from the parliamentary agent of the promoters, being embodied in an agreement to be scheduled to the Bill, such agreement to contain clauses as to the supply of electricity by the Corporation, and to the substitution of wood pavement for stone setts, if thought necessary, by the Corporation; and that the Tramways Committee be empowered to do what is necessary to carry out this resolution." The electrical engineer (Mr. Wilmshurst) told him, with regard to the working of tramways, that there was power sufficient at his works both to light the town and work the trams, and, should this consummation come to pass, the cost of electric light to burgesses might be less, simply because the machinery would be kept working night and day. This would undoubtedly tend to an increase in the use of electricity for lighting purposes. Councillor Baldwin seconded the resolution. Councillor Whitley moved, as an amendment, "That in the opinion of this Council it is not expedient to assent to the promotion of the present Bill, but that steps should be taken to consult with other boroughs with a view to joint action in obtaining powers to work tramways." The amendment was seconded by Alderman Gaukroger. Councillor Simpson, in supporting the amendment remarked that the overhead wire system looked like so many lines hung out to dry clothes on, and especially would this be the case in Halifax. He considered that the system they would have to look for would be the self-contained cars. They could not, he agreed with the Mayor, keep deferring this question of tramways for Halifax. With such developments, however, as seemed probable in the immediate future, he felt that they would be showing a wise discretion in withholding their hands, and seeing what the immediate future would bring to bear. The amendment was carried by a large majority.

Belfast.—Mr. Norton has delivered the tenth lecture of the electricity course in connection with the university extension. In introducing the subject of motors, he said the germ of the motor was to be found in the force exerted by an electric current on a magnetic pole, which implied also an opposite force on the wire carrying the current. Devices were shown by which this force was made to cause a continuous motion. The next type of machine depended on the successive attractions of an electromagnet on iron armatures fixed on the circumference of a wheel. This was the principle of Froment's early form of motor. An electric tramway acting on this plan was shown. The modern motor is simply a dynamo worked backward, turning energy of current into mechanical energy, instead of *vice versâ*. The actions of the different forms of dynamo when so used were explained, and specimens shown, including an electric tramcar model. The relation between the efficiency of the motor and the "back E.M.F." generated in the motor was explained. The lecturer then proceeded to sketch the modern development of alternate-current motors, showing an example of a "three-phase" asynchronous motor. The lecture concluded with an account of the electrical transmission of power, and the use of transformers in this connection. The report of the Belfast Street Tramways Company for the last half of 1895 states that the question of electric traction had not escaped the attention of the directors, and they consider the time has arrived for its application to Belfast, and with this view they have introduced a Bill into Parliament for the necessary powers to be granted to this company. The directors trust that they will be able to come to an equitable agreement with the Corporation, in the interests of the company as well as the city. Should they, unfortunately, not be able to come to any such agreement, they will have no alternative but to drop the Bill, as the directors are determined not to spend any of the shareholders' money in unnecessary parliamentary litigation.

Waterloo-with-Seaforth (Liverpool).—At the meeting of the Urban Council, Mr. Killey moved, "That the agreement with the Liverpool and District Lighting Company, Limited, now produced, embodying the terms under which the Council are prepared to give their consent to the application of the company for a provisional order, already deposited by them for supply of electricity in the district of the Council be approved and the seal of the Council affixed thereto." He said they had been able to get the maximum price proposed by the order reduced from 1s. per unit to 9d. They had also got several streets added to the limit of the number in which the company proposed to lay service mains. In addition the following clause had been inserted in the order—namely: "If the local authority shall receive from any one or more of the owners or occupiers of premises situate in any of the streets following—namely, Claremont-road, Seaforth-road, and that part of Sandy-road which lies between Claremont-road and Seaforth-road, a demand in writing for a supply of energy in such premises equivalent in the aggregate to seven units per hour the undertakers shall, without requiring any such guarantee as is mentioned in Clause 23 hereof, upon receiving a notice in writing from the local authority requiring them so to do and within such reasonable time as the local authority may in each case specify, lay down suitable and sufficient mains for the purpose of general supply throughout every part of the said streets at which a supply is from time to time required by any owner or occupier of premises situate in any of the said streets, and thereafter maintain the same." The order provided for the revision of the scale of prices every seven years, which the committee had managed to get reduced to three years. Then, under the order there was no restriction as to the locality of the generating station, but it was now agreed that no generating station should be erected or existing building utilised for that purpose without the approval of the Parliamentary Committee of the Council to the proposed site. With regard to the charges Mr. Killey stated that under the agreement the charge for the supply of electricity for public lamps or for public purposes was not to exceed two-thirds of the price for the time being charged to private consumers. After the committee had obtained those terms they felt that they could not withhold their opposition to the Bill. Mr. Colton seconded the motion, and it was carried.

London Lighting Extensions.—The Highways Committee of the London County Council recommend that sanction be given to the following: A notice dated January 22, 1896, from the County of London and Brush Provincial Electric Lighting Company, under the Wandsworth Order, 1892, of intention to lay mains in Christchurch-road (north side), Roupel-road, Palace-road (north side), Leigham-avenue (south side), and Leigham Court-road, and to construct four large transformer boxes in the last-named road; a notice dated February 4, 1896, from the same company and under the same order, of intention to construct 38 large transformer boxes in the Wandsworth district; notice, dated January 24, 1896, from the Kensington and Knightsbridge Electric Lighting Company of intention to lay mains and to construct street boxes in Michael's-grove. The undermentioned notices from the Vestry of Hampstead had been given in accordance with the provisions of the Hampstead Electric Lighting Order, 1892: (*a*) January 27, 1896 of intention to lay mains and construct a sub-station in Compayne gardens; (*b*) February 3, 1896, of intention to lay mains in Cleve-road (south side) and High-road, Kilburn; (*c*) February 5, 1896, of intention to lay mains in Goldhurst-terrace, Redington road (south side), Greencroft-gardens (north side), and the south side of Carfield-gardens. The Vestry is the undertaker under the order, and the Council had no power of approval or disapproval of these works. The Vestry of St. Pancras had given three notices, dated

Digitized by Google

respectively January 28 and 30 and February 3, 1896, of intention to lay mains (*a*) in Ossulton-street, and in and across Euston-road; (*b*) in Albert-road; (*c*) along and across Gower-street, and in part of Euston-road, in Lidlington-place, Houghton-place, part of two sides of Ampthill square, one side of Oakley-square, and across Eversholt-street. The mains to be laid in Gower-street are to consist of copper strip, and it was desirable that every possible precaution should be taken to prevent the accumulation of gas in the culvert. The committee recommended that the sanction of the Council be given to the works referred to upon certain precautions being taken. Sanction was also recommended to be given to the Westminster Electric Supply Corporation to lay mains across Vauxhall Bridge road, in and across Douglas-road, along Chapter street, in and across Moreton-street, and in Tachbrook-street. The committee recommended sanction to be given to the House-to-House Electric Light Supply Company to lay high-tension mains in Courtfield gardens and high and low tension mains in Collingham-gardens, and also to construct two small transformer boxes.

Leeds.—At a meeting of the City Council an important decision was taken with regard to the question of tramway traction. Mr. Hannam moved the adoption of the minutes of the Highways Committee, which included approval of the report of Dr Hopkinson recommending the trial of the Westinghouse conduit system of electric traction in a portion of Boar-lane. Mr. Hannam said that the majority of the members of the Highways Committee had been to London and seen a model at work on this system. To its working two objections were raised by the committee. They regarded the studs, which would rise from ½in. to ¾in. above the pavement, as being a source of danger to horses, as they would be very slippery. But that objection was met by the statement that the surface of the stud could be made as rough as any stone, and that there would be no more danger attaching to them than to the tramway rails. Their second objection was that the horizontal bar, or collector, might under certain circumstances become an obstruction, or be itself obstructed. Again they were assured that means could be devised whereby the bar could meet any reasonable or likely obstruction without being disconnected from the stud. Their objections on those two points having been met, the members of the committee were well satisfied with the idea of allowing an experiment with the system in Boar-lane. As to the cost, they had obtained an estimate for laying down the conduit system for a distance of 350 yards That estimate was £1,389, or about £4 per yard, as against £1. 5s. per yard on the overhead wire system. The Westinghouse Company would undertake to put this system down for £1 389, and after completing it they would allow the experiment to be continued for six months, and if it were then found unsuitable they would remove the conduits without the cost of a penny to the Corporation. Mr. Henry seconded the resolution. He said practically the Council was unanimous in favouring the adoption of electricity from Roundhay Park to Kirkstall, and if they adopted the Westinghouse conduit system in Boar-lane they would have at work three methods—viz, overhead side wires from the park to Roundhay-road end, the centre-pole system from that point to Boar-lane, and then the conduit system, with a reversion to the centre or side poles on to Kirkstall. Experimenting thus by three methods, they would in the course of a few months have evidence as to which was the best Mr. Willey moved as an amendment that the minutes of the committee be confirmed, with the exception of those relating to Dr. Hopkinson's report, which resolutions should be referred back to the committee. Alderman Baker seconded the amendment, remarking that everybody who had travelled on the Roundhay line heartily approved of it. Mr. C. H. Wilson proposed as a further amendment that the whole of the proceedings of the committee be referred back for further consideration. He explained that he was in favour of a uniform system of traction throughout the whole of the town from one end to the other. On the suggestion of the Mayor, Mr. Hannam undertook that the committee would consider the question of a uniform system throughout, and would at the next meeting of the Council be prepared with a recommendation, and thereupon Mr. Wilson withdrew his amendment. Mr. Willey's amendment was then put as the substantive motion, and was adopted.

Swansea.—The Corporation have decided to adopt a triple electric scheme of dust destruction, electric lighting, and tramcar propulsion. It was decided, before the work was begun, to take the opinion of Mr. Preece, C.B., and he has reported as follows: "I have carefully considered all that has been said against the proposals of the Town Council, but I have come to the conclusion that the Corporation would be quite safe in adopting Mr. Manville's several recommendations on their own individual intrinsic merits. Each part of the so-called triple scheme is practical and promising. They mutually support each other for the benefit of the ratepayers. The price charged for the light could be reduced to a figure below that of any other town in the United Kingdom. The demand for the light must consequently increase, and the number of lamps fixed would soon exceed the comparatively small number proposed to be installed by the Town Council. Swansea would become a pioneer town. Its inhabitants would benefit by having better transit, purer air, and cheaper light. Its finances would be improved by the profits that would arise from the successful administration of those purely local and municipal industries which the Legislature has decreed should be in the hands or under the control of the ratepayers themselves." A hitch has occurred in the negotiations for the purchase of the tramways. In consequence of the failure of the company to sign the contract of sale which had been prepared, a meeting of the Electric Lighting, etc., Committee of the Council was held on Monday afternoon. Subsequently the following report was officially supplied to the Press: "The Bill now before Parliament for the purchase of the tramways by the Corporation was considered, when it was pointed out by the chairman that an attempt was now being made by the company to depart from the terms originally proposed by the Corporation and accepted by the company. It was explained by the chairman that the amount proposed to be paid to the company—viz., £32 000—was intended to be employed as follows—*i.e.*, £10,400 to enable the company to discharge their existing mortgage debt, and the balance to be expended by the company in the purchase of motor cars for the working of the tramway system. The company, however, now required the Corporation to pay them the sum of £32,000 without the imposition of any restrictions. The committee, after full consideration, arrived at the conclusion that they could not depart from the terms originally proposed and accepted by the company. The several other modifications now asked by the company were considered, and the committee decided to agree to recommend the Corporation that as regards (1) the widening of streets necessary for the tramway service, the repayment by the company be fixed upon a 30 years' basis; (2) the Corporation agree to pay the cost of the accumulators provided the company pay for the transformers upon a 21 years' basis; (3) that the costs of the Bill be spread over a period of 30 years, the company contributing during the tenure of their lease—viz, 21 years; (4) the Corporation adhere to the provisions in the Bill as regards the Mumbles Railway service, it being understood that the Mumbles Railway Company are prepared to agree thereto; (5) the Corporation agree to purchase the plant at the end of the term—viz., 21 years—at a valuation, provided the plant is kept in proper repair to the satisfaction of the borough surveyor; (6) the efficiency or otherwise of the tramway service at any time to be a matter to be controlled by the Board of Trade." The town clerk was instructed to at once convey these terms to the company, and in the event of their non-acceptance he was directed to withdraw the Bill. A special meeting of the Town Council is to be held to day (Friday).

Dundee—At a meeting of the Gas Committee of the Town Council, the following report from Mr. Walter Brownlee, the engineer, with reference to the recent accident at the electric station was submitted: "I beg to report to you that on Tuesday, 21st ult., two accidents occurred at the electric lighting station here, whereby the supply of electricity to the city was suspended for five hours. About 10 a.m., or four hours after the pump engine had been started, the steam-pipe supplying the steam to this engine burst at the neck of the flange which is bolted to the steam chest, thus rendering the engine useless. This pipe was immediately removed and sent to Messrs. James Carmichael and Co. in order to have a new one made. Meanwhile the injector in the boiler-house was used for feeding the boilers, and was so used satisfactorily until 5.45 p.m., when the plug of the overflow valve gave way, rendering the further supply of water to the boilers impossible. With the assistance of the battery the city supply was kept up for about half an hour, when the water in the boilers had fallen to as low a level as was consistent with safety, and the fires had to be drawn, the supply of electrical energy being then discontinued. Every effort was made to get the necessary repairs effected as soon as possible, with the result that the injector was got into working order about 11 p.m, and the supply of electricity resumed at 11.15. The repairs to the pump engine were completed at 5 o'clock the following morning. The Board of Trade surveyor investigated the cause of the accident on 23rd and 24th ult., but up to the time of writing I have not received his report. In view of lessening the chance of a similar occurrence I would suggest the advisability of adding a third means of feeding the boilers, preferably by means of an electrically-driven pump. This could be driven by the current from the battery, and would thus be independent of the steam pressure at the time. Since the accident I have, as instructed by the convener, asked Messrs. Carmichael and Co. to put in a copper bend in place of the one which burst, as well as a copper pipe in place of the present duplicate steam feed-pipe, which is made of iron.' Messrs. Carmichael suggested certain improvements, and reported in regard to the injector, which is meant as a stand-by for any emergency, that they did not approve of it. They did not know any form of injector which could be relied on for this work, and advised in its place a combined steam-engine and pump of the Worthington type, suitable for feeding boilers at 160lb. pressure. It was stated that the improvements suggested by the Messrs. Carmichael had been duly carried out. The committee approved of what had been done, and saw no cause to blame anyone, being of opinion that what had occurred was an accident. They resolved to provide a new engine and steam-pump combined as an additional stand-by. At the same meeting the question of Dr. Hopkinson's patent for his three-wire system of electric lighting was under consideration. It appeared that the patent expires on July 27 next, and that Dundee, like Edinburgh, Glasgow, Hull, Bradford, and other towns, held a license from Dr. Hopkinson, who had given notice of an application to the Privy Council for an extension of the patent. Glasgow, the clerk stated, had convened a meeting of parties interested to be held at Westminster on 10th current to consider the whole matter. After a good deal of discussion, it was remitted to the clerk to instruct his London agents to attend the meeting and ascertain the course to be taken and the expense of joint opposition, after which the committee will decide on the matter. In the course of further conversation, Mr. Ballingall (the convener) suggested that hereafter the burgh engineer should make the necessary openings in the streets for the laying down of pilot wires, and thus save expense. The committee agreed to instruct Mr. Mackison accordingly.

PROVISIONAL PATENTS, 1896.

FEBRUARY 3

2419. Improvements in electric pendulum indicators. Frederick Jones, 76, Wakehurst-road, New Wandsworth, London.

2427. An improvement in apparatus for measuring electrical resistances. Ernest Howard Griffiths, 28, Southampton-buildings, Chancery lane, London.

2435. An improved dialytic process of decomposing stable salts and thereby creating electrical energy. Carl Buderus and Joseph Menz, 45, Southampton buildings, Chancery-lane, London

2437. Improved means of applying the heat of the electric arc for welding, soldering, and other purposes. Albert Hirsch, 53, Chancery-lane, London.

2447. Improvements relating to telephones. Muirhead and Co. and Francis Lauder Muirhead, 124, Chancery-lane, London.

2459. Improved apparatus for electric welding, soldering and other purposes for which intense local heat is required. Albert Hirsch, 53, Chancery-lane. London.

FEBRUARY 4.

2501. An improved system for conveying and furnishing electricity to railway cars and devices used in connection therewith. Alvaro S. Krotz, William P. Allen, and Oliver S. Kelly. 5. John Dalton-street, Manchester. (Complete specification.)

2523. An electric railway system. Augost Casazza, 321, High Holborn, London.

2545. Improvements in automatic current-regulators. Henry Harris Lake, 45 Southampton-buildings, Chancery-lane, London. (Stanley Charles Cuthbert Currie, United States.) (Complete specification.)

2570, Improvements in telephone systems. Wallace Augustus Houts, 53 Chancery-lane, London.

2581. Improvements in telephonic apparatus. Edward Wythe Smith and the New Phonopore Telephone Company, Limited, 66, College-street, Chelsea, London.

2594. An improved electrolytic process for extraction of caustic alkali and of hydrochloric acid from a chloride. Alfred Julius Boult, 323, High Holborn, London. (Fabio Villani, Italy.)

FEBRUARY 5.

2610. Improvements in the construction of dynamo-electric machines and electromotors. Edmund Scott Gustave Rees, Wolverhampton.

2665. A new non-inductive adjustable carbon resistance. Sydney Pratt Blackmore, 28, Southampton-buildings, Chancery-lane. London.

2666. An improved fluid for use in galvanic batteries and the like. John Edward Preston, 17, Harp-lane, Great Tower-street, London.

2674. Improvements relating to armatures for dynamo-electric machinery. P. R Jackson and Co., Limited, and Joseph Slater Lewis, 31, High Holborn, London

2677. The manufacture of a new or improved substance or product suitable for use as a substitute for vulcanite, hard woods, or other hard materials, or for other uses or purposes for which same may be applicable. Henry Birkbeck, 31, Southampton-buildings, Chancery-lane London. (Pieter Wichers Wierdsma and Johannes Kuipers, Holland.)

2683. Improvements in electricity meters. George Hookham, 18, Southampton-buildings, Chancery-lane, London.

FEBRUARY 6.

2707. Improvements in incandescent electric lamps, holders, and the like. Archibald John Howard, Euston Villa, Cheddon-road, Taunton (Complete specification.)

2717. Improvement in controlling switches for dynamo-electric machines. Frederick Henry Royce and Ernest Alexander Claremont, Hulme, Manchester. (Complete specification.)

2745. Improvements in apparatus for blowing organs by electric motors. Bernard Mervyn Drake and John Marshall Gorham, 66, Victoria-street, Westminster.

2755. Improvements in the treatment of indiarubber and indiarubber compounds or substitutes for indiarubber. John Barclay, 7, Staple-inn, London.

2767. Improvements in telephonic systems and in switching apparatus for use therein. Alfred Roeling Bennett and George John Somerville, 45, Southampton-buildings, Chancery-lane, London. (Complete specification.)

2772. Method and apparatus for effecting the connection in parallel of alternate-current and polyphase dynamos and motors. Siemens Bros and Co., Limited. 28, Southampton buildings, Chancery-lane, London. (Siemens and Halske, Germany.)

2773. Improvements in and connected with portable electric lamps. Charles Nestor Gauzentes, 4, South-street, Finsbury, London.

FEBRUARY 8.

2873. Improvements in culverts for electrical conductors and means of supporting the conductors therein. Henry Lewis Doulton and Charles Edward Morriss, Lambeth Pottery, Lambeth, London.

2875. Improvements in or connected with electric incandescent lamps. Herbert Hampton Hall and William David Cheyne 57, Barton-arcade, Manchester.

2894. An improved electric alarm clock. Alfred Herbert Webb, 70, Wellington-street, Glasgow.

2909. Improvements in secondary or storage batteries. Luis Falero and Henry Lumley 78, Fleet-street, London.

2915. An improved electric gas igniting and extinguishing apparatus. Alfred Czarnikow, 31, High Holborn. London. (Complete specification.)

2923. Improvements in alternate-current dynamos. Walter Claude Johnson, Louis John Steel, and John William Ewart, 28, Southampton-buildings, Chancery-lane, London.

SPECIFICATIONS PUBLISHED.

1892.

785. Incandescent electric lamps. Ries. (Second edition.)

4523. Incandescent electric lamps. Ries Electric Speciality Company and others (Second edition)

1895.

1202. Telephonic apparatus. Langdon.

3087. Telephone system. Lake. (Shea and another.)

3531. Printing telegraphs. Kamm.

5236. Starting electric motors. Ravenshaw and others.

5336. Dynamo-electric machines. Blackburn and Boyden.

5521. Electric couplings. March.

8210. Magnetic needles. Gisborne.

11748. Electric bell systems. Hodgson and Edwards.

22006. Electric railway systems. Murphy and Pierce.

23658. Electric railways. Rosenholz and Poehlman.

23855. Electric switches. Edison and Swan United Electric Light Company, Limited, and Proctor.

24166. Incandescent electric lamps. Edison and Swan United Electric Light Company, Limited, and Gimingham.

NOTES.

New Book.—We have received from Messrs. Alabaster, Gatehouse, and Co., Paternoster-row, a copy of "Applied Magnetism: an Introduction to the Design of Electro-magnetic Apparatus," by J. A. Kingdon, B.A.

Shop Windows.—It appears that in the United States shopkeepers troubled in winter time with frosted windows have found that by thorough ventilation, by means of electric fans, this source of annoyance may be obviated. The *Electrical World* states that in some cities the electric fan is beginning to be extensively used for that purpose.

A Novel Tariff.—The *Journal Télégraphique* describes a form of telephone tariff which has been introduced in Switzerland. A system has been started under which the annual subscription is 40fr. (£1. 12s.), but all conversations are paid for at the rate of 5 centimes (½d.) each. One advantage of this system is stated to be that it gets rid of the use of the wires for merely idle conversation. It might if the subscribers were very frugal folk. But what an amount of work it must make to keep count of the half-pennies.

Telephone to Belgium.—According to the *Zeitschrift für Elektrotechnik*, the Belgian Telegraphic Administration recently made an attempt to establish submarine telephonic communication with the English coast. The line was between Veurne in West Flanders and Dover, and two wires of the Dover and Belgian telegraph cable were used. The attempt succeeded better than might be expected, and communication was clear between Dover and Veurne, but could not be prolonged to Brussels. It was, however, thought that it was only an improvement of the land lines to London and Brussels that was necessary to make direct communication practicable between those two cities.

High-Tension Illumination.—The *Chronik* of the Vienna Elektrotechnischen Verein contains notes of the work of Mr. P. Spies, of Berlin, on high-tension illumination. Tesla's work is referred to, and Mr. Spies thinks that what has been done in this direction will not end with the production of mere playthings, but that in all probability in the development of the Geissler tube will be found the "light of the future," a light without heat. In this way the parasite heat rays which in our present electric installations reduce the energy effective in giving light to from two to four per cent. of the whole, will be reduced to a minimum, and for the first time in the arts a cold body will come into use as a source of light.

Telegraphs in 1895.—The Berne *Journal Télégraphique* of January 25 says that the past year has been one of great slackness so far as concerns the development of telegraphic network. From a table given it would seem that, while the average length of submarine cable laid has been 12,151 kilometres (7,534 miles) yearly, during 1895 the only cables completed were those from Madagascar to Mozambique, and from Obock to Jibuti, the aggregate length of which probably would not exceed 620 miles. There are, however, abundance of proposed lines. As a whole, telegraphic lines show an increased length of only 3 per cent. for the year's progress, this figure not apparently including the duplication of lines. On the other hand, telephone lines have shown a steady advance.

Appointment.—Mr. William Wilson, M.A., Bristol, has been, out of 65 applicants, unanimously elected principal of the municipal technical school at Salford, at a commencing salary of £350 per year. This technical school is in course of erection by the Corporation, at an estimated cost of over £70,000. It has separate departments for the teaching of spinning, weaving, dyeing, chemistry, physics, electrical and mechanical engineering, art, cookery, dressmaking, etc. After graduating in 1887 at Aberdeen University, Mr. Wilson held several appointments in Edinburgh—acting as demonstrator and assistant professor of physics in the Heriot-Watt College—and for the last five years he has been connected with the Merchant Venturers' Technical College, Bristol, where he has held the appointment of professor of applied phyics and electrical engineering.

The Telephone Service.—The movement at Manchester in favour of the municipalisation of the telephone service has received a decided check. A town's meeting, presided over by the Lord Mayor, was held on Tuesday to consider the question, and the attendance included the leading merchants and manufacturers of the city. On a resolution, however, in favour of applying to the Post Office for the necessary powers to carry out the project being submitted, it was rejected by a very large majority. From the speech of one of the opponents of the motion, it would appear that a fear of increasing the rates was largely responsible for this result. According to a letter of Mr. Fred Scott, hon. secretary of the Municipal Telephones Association, to the *Manchester Guardian*, a large number of the telephone company's employés were present and voted at the meeting.

Indian Railways.—In reference to the electrical communication now being fitted to the carriages composing the mail trains on the South Indian railways, the *Madras Times* says that this is a most necessary precaution in view of the outrages which have been committed by *badmashes* on women travelling alone on certain portions of the line. Our contemporary, however, remarks that it is hoped that the old method of protecting the electric "stop" by a cover of glass which has to be broken to make use of the contrivance has been superseded on the South Indian Railway by some more modern and more simple invention. Some more simple arrangement might be devised for carriages reserved for ladies. A trial trip has been made between Madras and Pallavaram with carriages fitted with intercommunication, and proved a successful one, five stoppages by means of the new arrangement having been made during the run.

The United Kingdom Telephone Defence Association.—An association under this name is being formed to endeavour to promote more efficiency and economy in the existing telephone system, so that a better service and lower rates may be secured. It will also advocate legislation with a view to the extension of the use of the telephone to all classes of the community by the prevention of monopoly in telephonic supply. About 60 influential names have been secured for the general council, and the executive council consists of Prof. Silvanus P. Thompson, Mr. R. E. Crompton, Major-General Webber, Mr. A. R. Bennett, Mr. Charles R. Haig, Mr. James Swinburne, Prof. A. B. W. Kennedy, and Mr. H. H. Bridgman. The offices of the association are at 27, Chancery-lane, W.C. The aims of the association deserve all sympathy, and it is to be trusted that its efforts will be more successful than the previous attempts which have been made in the same direction.

Mining Engineers.—The general meeting of the Federated Institution of Mining Engineers was held at Sheffield on Wednesday. In the course of a paper on the "Goldfields of Matabeleland," Mr. F. Shaw referred to what might be done by the transmission of power derived from the Victoria Falls, on the Zambesi River, some 150 miles from Buluwayo. In these falls, he said, there was undoubtedly sufficient energy to run all the machinery required for the next 20 years in the numerous gold districts, and a company had already been floated to

Digitized by Google

utilise that source of power. It will be remembered that both as to height and volume of water the Victoria Falls are among the very few waterfalls in the world that can in any way come into the same class as Niagara, so that if the enterprise referred to by Mr. Shaw is carried out, the work will be a great one. At the same meeting a paper was read by Mr. T. Scott-Anderson on "Electrical Welding." The next meeting of the institution will be held in London on June 4.

The Best Light.—A communication from Mr. Elihu Thomson on the subject of the effect, pleasing or otherwise, of various tints of light on the eye is given a prominent position in the New York *Electrical Engineer*. Most persons will agree with Mr. Thomson that the tint of sunlight is the standard to be worked up to. A believer in the doctrine of evolution must, of course, admit that the eyes of man have been developed more perfectly to use daylight than any other light. The old-time ghastliness of arc lights seen at night, which used to be talked about a great deal but which is seldom referred to now, was due to accumulated experience of the race leading to expect that every light used at night should have a red or yellow tint. This education or inherited tendency has rapidly been evolved out of existence, and even the greenish ghastliness of the Welsbach burner does not seem to be one-tenth as offensive as it was on the first advent of the burner. This may, however, be due in a measure to a change in the composition of the network rather than to education.

The Magnetic Field.—Mr. J. C. Beattie's paper on the behaviour of various alloys in a steady magnetic field has been published in the *Proceedings* of the Royal Society of Edinburgh. The variation of resistance in bismuth is known to be great, and it was found that in alloys of bismuth it was greatest in those which contained most of that element. In all cases the variation was an increase. In antimony-zinc and antimony-cadmium alloys no variation was observed. Mr. Beattie also investigated nickel, antimony, and tellurium unalloyed, and found that the decrease of resistance in a nickel plate placed perpendicular to the lines of force in a steady magnetic field, and the increase in the resistance of plates of antimony and tellurium similarly placed are proportional to the square of the magnetisation. It would appear that the direction of the transverse effect in a conductor follows the thermoelectric series, the metals from bismuth to silver giving a negative effect, while those from zinc to tellurium give a positive effect; cobalt is an exception.

Endowment of Experiment.—A Bill has been introduced into the United States Congress for the establishment, in connection with State colleges and universities endowed with the proceeds of national land grants, of experimental stations for the mechanical arts, which shall, in their relation to engineering education and scientific investigation, be analogous to the several existing State agricultural experiment stations with respect to agricultural science. To accomplish this it is only necessary to extend the provision of the Hatch Act of 1887. It is proposed that the internal organisation of such engineering experimental stations follow closely that of the official stations now to be found in every large German town in connection with its university and technical school, and especially of the mechanical testing station at Charlottenburg, Germany. It is desired that what has been done by private munificence in several of the laboratories of American technical schools should be extended and made possible by Federal aid in every land-grant college and university.

Royal Meteorological Society.—At the monthly meeting of this society, held on Wednesday evening at the Institution of Civil Engineers, Westminster, Mr. Edward Mawley, F.R.H.S., president, in the chair, the report on the phenological observations for 1895 was presented to the meeting. Mr. R. H. Scott, F.R.S., read a paper on the recent unusually high barometer readings in the British Isles, in which he stated that the daily weather chart for 6 p.m. on January 8 was the first in these islands that ever showed 31in. The station was Stornoway, and by the next morning all over the northern portions of Great Britain and Ireland the barometers were above 31in. The highest reading of all was 31·119in., photographically recorded at Glasgow at 9 a.m. on the 9th. Mr. R. Inwards, F.R.A.S., then read a paper on "Turner's Representations of Lightning," which he considered to be true to nature, and demonstrated this by placing an actual example of Turner's work side by side with a photograph of a real flash of lightning. In reference to this it may be remarked that it has long been a matter of wonder to the common man that the traditional zig-zag flash seen in most artists' work should have persisted so long. No one ever saw anything like it in nature.

The General Public.—The New York *Electrical World* appears to have a poor opinion of the attempts made at popular science by the non-technical Press of America. Our contemporary begins an article on the subject by stating blankly that "the reader who derives his information entirely from the newspaper Press is indeed fortunate if he possesses a single correct idea on electricity or its applications. It would almost appear that those who write for the general public on technical subjects possess such a supreme contempt for their audience that they consider it only worthy of being fed with the scraps contemptuously cast aside by those who know, or with speculations manifestly ridiculous to even the first-year student in electricity." When an article is ordered for a popular audience, the writer, "instead of giving the subject and the manner of presentation the careful study always necessary in order to intelligently address a lay audience, finds it much easier to collect the odds and ends of visionary speculation and present them in a picturesque garb, or to take unmature subjects and write of them as if they were actual practical accomplishments." This is, of course, very regrettable, but it is hardly fair to put all the blame on to the authors. That sort of thing is probably asked for because the public like it.

A Cable Proposal.—A recent number of *El Telegraphista Español* contains an article by Mr. Angel Guerra on the subject of a new Transatlantic cable from Spain to the West Indies. The route advocated is from Teneriffe to Puerto Rico, and thence to Cuba and Mexico. To the objection that the Spanish Exchequer is hardly at present in a position to disemburse the 20 or 30 million pesetas that the cable would cost to lay, it is suggested that a commercial company might be found willing to do the work in return for 10 or more annual payments. The Spanish cable to the Canaries appeared at one time a very difficult matter to bring about. Nevertheless, Spanish patriotism conquered the difficulties in its way, and this cable, which at the commencement maintained only an anemic existence, has now become one of the most productive of lines, bringing in more than 400,000 pesetas (£16,000) a year. It is remarked that at present the Spanish Government has to pay large sums to foreign telegraph companies, and that in particular since the Cuban insurrection commenced in March last it has cost the Spanish Government more than a million pesetas for official telegrams. On the other hand, by the payment of three times that sum annually for 10 years the Spanish Government would become the possessors of what would be "one

Digitized by Google

of the most important telegraphic lines in the world." Whatever may be thought of the scheme of construction proposed, the desire on the part of the Spaniards for a line of their own to connect them with their West Indian colonies and the Spanish-speaking part of America is a natural one.

Chimney-Shaft Stability.—Mr. F. J. Bancroft read a paper on the "Stability of Tall Chimneys" before the Institution of Junior Engineers last Friday. Mr. Bancroft enumerated the characteristics exhibited by chimneys that had fallen. Such shafts had usually been observed to "sway" or "rock," which movement, although a source of alarm to some people, had by others been regarded as an essential condition of safety, as showing the admirable elasticity possessed by the structure; cracks had also been traceable, starting on the windward side and descending obliquely to the leeward side of the shaft, which had finally collapsed by the crushing of the material through the concentration of the pressure on one side. The author combated the idea of rocking being indicative of safety, and showed that separation must take place at the joints, while the swaying, with its concomitant pressure and relief, promoted disintegration, and caused the shaft to be still less capable of resisting the recurring wind pressure. In conclusion, attention was directed to the danger attending the practice of increasing the height of a shaft in order to obtain more draught. The velocity of gases up the chimney being proportional to the square root of the height, increased duty was better obtained by larger diameter than by greater height. It was, therefore, advisable to have ample area in designing a chimney. A discussion followed.

Accident.—An accident is reported to have taken place last week at the Southport electric lighting works at Crowlands, in which a man received a current at a pressure of 2,000 volts through unusually good contacts and still survives. According to the *Southport Guardian*, a workman named John Williams was standing against No. 2 rectifier trimming the brushes in readiness for the evening's work, and while thus engaged his right leg accidentally touched a brass screw-head in the wooden guard protecting what is known as the water switch, and some keys in his pocket serving as a conductor, the full pressure of the current—2,000 volts—passed through his body, the circuit being completed by his right hand on the top of the machine. He was at once rendered unable to move, but a fellow-workman, Robert Black, seized him by the clothes and dragged him forcibly away. The current had burned a large hole in the flesh of the leg, while on the hand some of the bones were exposed. Williams was quite unconscious, and apparently lifeless, but rubbing and other means of restoring respiration and consciousness were resorted to, and in less than 10 minutes these efforts were to a large degree successful. The injured man was removed to the infirmary, where he was detained as an in-patient, and during the day he showed a marked improvement. As to the cause of the accident, it was afterwards ascertained that the brass screw referred to just pierced the wooden guard, the point coming in contact with the metalwork of the rectifier. It was not a part of the machine, but a screw used merely for holding in position a connecting-rod, which is hung outside the guard when not in use, and nobody was aware that it touched the metalwork inside.

A Workhouse Telephone.—The telephone system which has been installed at the Birmingham workhouse infirmary at Spring Hill is claimed to be unique in regard to the variety of the communicating apparatus there concentrated on a single switchboard. A clock surmounts the structure, immediately beneath being the alarm-bells for fire and emergency. Below the bells are panels, in which the code signals are exhibited. In front is suspended the attendant's transmitter, which is of the Hunningscone type. The adjustment to any desired height is effected by a patent spring roller. On either side of the indicators and switches are panels, and on these, within easy reach of the attendant, are "plunger pushes" for the fire-alarms, bell to the nurses' home, the boiler-house, and the doctor's call-bell. The switchboard has been so designed that it can be removed from its position against the wall to allow of any alteration or repairs without interrupting the communication. This is effected by means of flexible cables between the terminal-board and the switchboard. The wires on the terminal-board are all fixed to brass plates bearing their name and number, to facilitate the testing necessary to locate a faulty line. In the old switchboard no such arrangement was made, and as a consequence the rear was a mass of tangled wires, and thus the utmost difficulty was experienced in getting at the working parts of the board, to say nothing of the liability to faults. The switchboard was designed by Messrs. Walker Bros., Birmingham. It is computed that the telephone lines within the infirmary and surrounding grounds now extend to something like 20 miles, the infirmary buildings covering an area of about 3½ acres. The recent improvements have been personally supervised by Mr. J. B. Walker, chairman of the Infirmary Management Committee, who, in common with the other members of the committee, has left nothing undone to make the arrangements as perfect as possible.

Modern Apparatus.—Mr. W. J. Buckley, in a paper read before the North-Western Electrical Association at Milwaukee, Wisconsin, gives the following table of efficiencies of 100-volt 16-c.p. lamps as the result of a test made with some of the prominent makes:

	Amperes.	Watts.	Watts per c.p.
Thomson-Houston ...	·62 ...	62 ...	3·875
Edison	·55 ...	55 ...	3·437
Buckeye	·56 ...	56 ...	3·500
Packard	·57 ...	57 ...	3·362
Bernstein	·65 ...	65 ...	4·062
Beacon	·54 ...	54 ...	3·375
American	·58 ...	58 ...	3·625
Columbia	·61 ...	61 ...	3·800
Keystone	·56 ...	56 ...	3·500

In the course of an extensive survey of the existing state of electrical practice in America, Mr. Buckley advocates direct-connected dynamos, 2½-watt lamps, large transformers, high frequency, unless the power service is more important than the lighting, in which case a low frequency should be adopted. If the power service is in small motors the system should be single phase, but if motors of more than 50 h.p. are to be driven a multiphase system is better. On this subject it is remarked: "When the purchaser comes to buy alternating apparatus he is confronted with single-phase, quarter-phase, two-phase, three-phase, multiphase, and monocyclic—surely enough to feaze him to start with. But what system will fit his conditions? Which machine should he buy? With the use of an efficient motor the single-phase is the ideal alternating-current system. No condensers, no balancing of the load, no fixed arbitrary line loss, but two wires on the line, all giving a flexibility that affords a minimum cost in power, arc and incandescent services from the same machine and circuit. All the catalogues of multiphase apparatus contain statements, variously expressed, that a single-phase synchronous motor is the most desirable but unattainable type. This is no longer true as to unattainability. Single-phase motors are now sold on the market having as high a commercial efficiency as is obtained in any but the large types. They are self-starting at full load with maximum torque. They require no special circuits or connections, no starting

Digitized by Google

rheostat, no condenser, and no special transformer, the ordinary lighting transformer answering the purpose. Being in step with the generator, the regulation of the synchronous motor is perfect under all loads, and the motor will pull out of step and stop running if more than a 50 per cent. overload is applied."

Motorcarts.—By invitation of the vice-presidents and council of the Motorcar Club, several members of the House of Commons, and a number of social and commercial magnates, were shown on Saturday a practical display of horseless vehicles, given in the North Gallery and West Gardens of the Imperial Institute. Among those present were Prince Edward of Saxe-Weimar, Sir William Harcourt, M.P., Dr. Rentoul, M.P., Mr. Atherley-Jones, M.P., Sir Frederick Abel, Sir J. Somers Vine, Mr. Hiram Maxim, Mr. H. H. Cunynghame, Mr. H. J. Lawson, Mr. Bertram Van Praagh, Mr. Frederick R. Simms, and the Hon. Evelyn Ellis. Four cars were exhibited, three of them driven by oil motors and the fourth by electricity. This car was the work of Messrs. Garrard and Bumfield, of Coventry. All the cars were shown in operation, under the superintendence of the Hon. Evelyn Ellis and Mr. F. R. Simms, and subsequently Mr. Bertram Van Praagh, vice-president of the club, delivered an address, in which he ventured to prophesy that motorcars would before long form one of the greatest industries of the world. In reference to this subject, it is stated that the Government Bill dealing with motorcart road traffic has been prepared, and will be introduced shortly. It is based on the lines of Mr. Shaw-Lefevre's Bill of last year, but it deals with the question more broadly. It contains no provision restricting the speed at which the new vehicles may be driven, any abuse being left to be dealt with by the ordinary law against the reckless driving, so that the English law will be rendered more favourable to the new traffic than that of France. There appears at present to be no opposition to the Bill, and the members who have interested themselves in the matter believe that the result of its passing will be the immediate appearance of a number of the new vehicles on English roads. Several road authorities have during the week decided to petition in favour of the Bill. Few things are more remarkable than the complete change that has taken place in public sentiment in reference to the introduction of this kind of vehicle. It is not so very long ago since every horseowner would have been up in arms against it.

The Rontgen Radiations.—A large number of experimenters have been at work on this subject during the last fortnight, but little has been done towards coming to any definite conclusion as to the nature of the new radiations. According to the *Elektrotechnischer Anzeiger*, Mr. Alfred Wehrsen has obtained them in Berlin with the help of an influence machine, while at Renfrew, Lord Blythswood has obtained Röntgen photographs by using the brush discharge of his fine Wimshurst induction machine. It would therefore appear that a high vacuum is not an essential condition for the production of the new radiations. An important discovery of Lord Blythswood's is that the Röntgen rays are liable to something equivalent to colour absorption, for on placing strips of coloured gelatine in front of the photographic plate, the blue was least sensitive, red next, and yellow most. The connection of this fact with the colour of the light in the Crookes tube during the discharge may have an important bearing on the theory of the subject. There are on record several curious experiments in which an effect has been produced by very strong lights on a sensitised plate enclosed in a metal case. Metal dark slides being in common use, these have been hitherto generally discredited or referred to the action of the "heat rays." Several French observers now state that a photographic effect is obtained on a plate enclosed between sheets of metal not only with the electric arc, but even with a petroleum flame if the exposure is long enough. The experiments of Mr. Le Bon in this direction have been accepted by the Paris Académie des Sciences, and the phenomenon must therefore be accepted as a real one. In one case cited the image of an aluminium medal was obtained in this way after an exposure of two hours. The Académie have also received communications from Messrs. Benoist and Hurmuzescu on the action of the new rays in causing a discharge of the electroscope, and from Mr. Chabaud on the transparency of metals to them. Platinum ·01mm. thick was absolutely opaque, as was mercury in a thickness of ·1mm. Other metals were transparent in various degress. The subject was also discussed at last week's meeting of the Royal Society, when a paper by Lord Kelvin on the generation of longitudinal waves in ether was read, in which was described an arrangement for obtaining pressural disturbance through a considerable space of air, accompanied by a very small proportion of ordinary transverse waves. A paper by Prof. J. J. Thomson was also read relating to experiments, from which he concludes that all substances when transmitting the Röntgen rays are conductors of electricity. In the course of the discussion which followed Captain Abney said he ventured to doubt whether the action of the Röntgen rays on a sensitive plate could properly be described as photographic. Several facts, in his opinion, indicated some preference for the view that the Röntgen rays acted by first setting up phosphorescence or action of some unknown kind in the glass at the back of the sensitive film. A large number of experiments were also described by Prof. Dewar, showing that resistance to the passage of Röntgen rays increased with increase of atomic weight. Organic substances were all relatively transparent, following the carbon, oxygen, hydrogen, and nitrogen of which they are composed. Mere complexity of structure made no difference, but substitution products showed increasing opacity in the order of the atomic weights of the combined chlorine, bromine, and iodine. It has also been reported in the non-technical Press that M. Carmichael, of the Faculty of Sciences at Lille, has worked out a way of reflecting the new radiations from steel mirrors. He can thus, he says, use them on photographic plates set between the mirror and a Crookes tube. A clear image is thrown back by the mirror on the plate. A most remarkable report was one that Prof. Salvioni, of Perugia, had succeeded in the conversion of the Röntgen rays into visible light. Startling as this might seem, it was on the longitudinal vibration theory by no means impossible, it being one of the troubles of that theory that under certain circumstances there ought to be a conversion of a part of the vibrations from transverse to longitudinal, or *vice versâ*. A description of Prof. Salvioni's instrument has, however, appeared in a footnote of the *Proceedings* of the Vienna Elektrotechnische Verein, published in the *Zeitschrift für Elektrotechnik*, from which it appears that the essential part of the apparatus is a black paper tympanum, treated with some substance that fluoresces under the action of the Röntgen rays, and mounted in a cylinder. It is therefore merely a fluorescence effect, and not a case of direct conversion. The image is produced on the tympanum by the "shadow" from a Crookes tube at one end of the cylinder and viewed through a lens at the other. Before quitting the subject, it may be remarked that one experimenter has considered that the suggestion that the rays might be used as a germicide was worth following up. There was, of course, a negative result.

LECTURE XXV.

(Specially Contributed.)

Wattmeters.—These are combination instruments, and before describing them it will be well to see how ammeters and voltmeters are used. Although it is usual to look upon the insertion of an ammeter into a circuit as not altering the conditions of the circuit, its use means increase of resistance, hence an alteration of condition. In practice, however, it is necessary to know the current, and so the use of instruments is an evil that cannot be remedied. To know the current effect in any circuit, the ammeter must be so placed as to indicate the total current effect of that

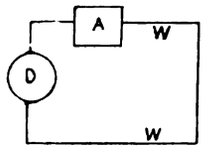

FIG. 1.

circuit. Thus (Fig. 1) the ammeter, A, indicates the total current through circuit, W W. Similarly Fig. 2, although

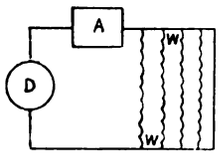

FIG. 2.

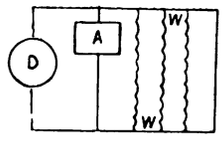

FIG. 3.

in this case the circuit comprises several branch circuits If, however, the ammeter is connected as in Fig. 3, it indicates the current in that branch circuit only, and not the total current generated by the dynamo. In all cases the ammeter is put in series with the resistances forming the other parts of the circuit. Branch or parallel resistances, as I have before explained, are equivalent to increasing the sectional area of all or part of the conductor of the circuit. This I might indicate diagrammatically by Fig. 4, which again is electrically the same

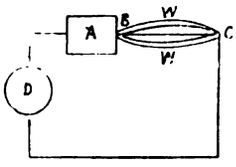

FIG. 4.

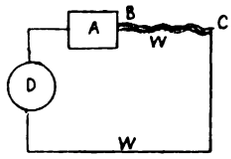

FIG. 5.

as if the conductor strands from B to C were twisted, as in Fig. 5, to form one single conductor. We do not look upon a conductor made up of a number of strands as a circuit of a number of parallel branches, yet it might be so looked upon. Once more, then, adding branch circuits is equivalent to increasing the area of a conductor, nothing more, so far as circuit resistance or total current is concerned.

The voltmeter, however, is not used like the ammeter. It is put in parallel with the conductor between the two points, the difference of potential between which is to be

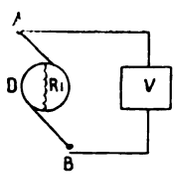

FIG. 6.

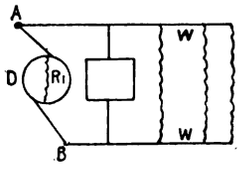

FIG. 7.

found. Thus (Fig. 6) A and B represent the terminals of a dynamo, R_1 the armature resistance of the dynamo. To get the difference of potential between A and B, we join the two points through a voltmeter. In this case there is no other external circuit, and the dynamo would be said to be on open circuit. If, however, there is an external circuit, W W, as in Fig. 7, the voltmeter is still in parallel now with both internal and external resistances.

The ammeter is placed in *series* with the other circuit resistances.

The voltmeter is placed in *parallel* with the other circuit resistances.

The ammeter measures amperes, the voltmeter measures volts, and we have seen that for steady currents the product of amperes and volts is watts. If, then, we can get an instrument indicating the product of amperes and volts, its indications will be in watts. The wattmeter is such an instrument. The consideration of the difficulties introduced by alternating currents would lead us too far afield, so we must for the present restrict our description to the instruments for steady currents. Fig. 8 combines on one diagram the method of connecting up ammeters and voltmeters. D indicates the dynamo, A the ammeter, V the voltmeter, and W W the external circuit. Recall what has been said of electro-dynamometers. If we have two conductors, A and V (Fig. 9), one at right angles to the other, the tendency of the conductors when a current goes through each is to become parallel, and the measure of this tendency is equal to the product of the two currents.

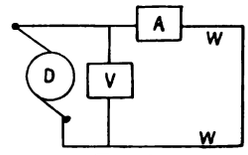

FIG. 8.

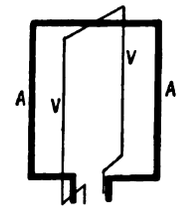

FIG. 9.

Then, if one coil is connected up as an ammeter and the other as a voltmeter, the measure of this tendency is the product of the currents in the coils; but one of these currents is the full current in amperes; the other varies as the pressure in volts, and the product—amperes and volts—will be proportional to the watts, and thus the instrument may be graduated as a wattmeter. In an instrument so arranged, one coil, or set of coils, must be of low resistance to be connected as an ammeter; the other coil, or set of coils, must be of great resistance to be connected up as a voltmeter. You will see that the difference between an electric dynamometer and a wattmeter is that in the former the same current goes through both coils, while in the latter the currents are different.

Kinds of Wattmeter.—Instruments of this kind are divided into two classes, known as *indicating* wattmeters and *integrating* wattmeters. The province of the first kind is simply to indicate the instantaneous value of the volts and amperes, while the second class do not indicate instantaneous values, but integrate the total energy delivered to the circuit during the time through which they are attached to it. Thus the readings of the latter are in watt-minutes, or watt-hours.

Thomson Wattmeter.—As an example of this class of instrument I may describe one designed by Prof. Elihu Thomson, and shown in Fig. 10. It consists of two vertical coils, which constitute the field coils of the armature shown inside. The field coils are fixed; the armature revolves. Neither field coils nor armature contain iron. The field coils we may call the ammeter part of the instrument. They are in series with the circuit, and all the current goes through these. The armature, which is of the Siemens drum type, is hollow, and is made of a fibre cylinder, over which the coils are wound. On the end of the shaft of the armature is a silver commutator, on which rest flexible bronze brushes provided with silver contact-pieces. The armature forms the pressure or voltmeter coil, and is connected in parallel. The armature resistance is high in itself, but in order to still further increase the resistance of the branch circuit a high resistance of fine wire is connected in series with it. These parts of the instrument form the wattmeter proper, but to make it a practical instrument other important details are added. An essential point is the slowing mechanism. The shaft of the pressure coil is

Digitized by Google

carried downwards, and on it, a little distance below the coil, is fixed a copper disc. This disc rotates between the poles of three permanent magnets, which, as the disc rotates, generate eddy currents in it. Thus the reactions between the copper disc and the permanent magnets cause a drag or load on the motor, and this drag or retarding effect is directly proportionate to speed. At the top the

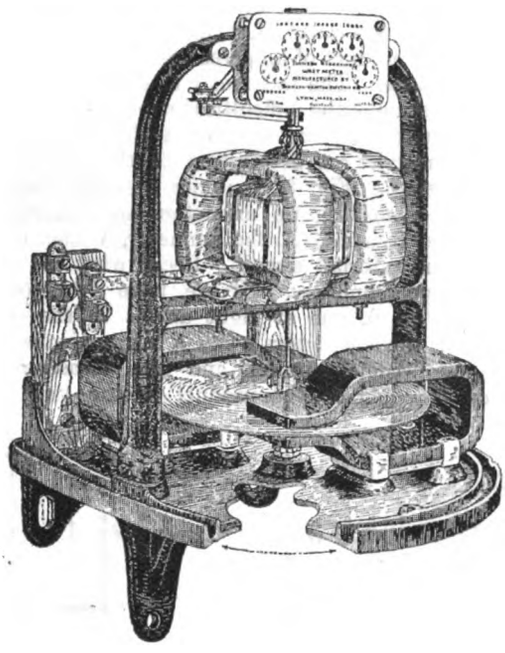

FIG. 10.

motor spindle engages a train of gears, which cause the dials to show the power consumed in the circuit in watt-hours.

THE ELECTRIC STREET RAILWAY SYSTEM OF MONTREAL, CANADA.

At the ordinary meeting of the Institution of Civil Engineers on Tuesday, the 18th inst., Sir Benjamin Baker, K.C.M.G., the president, in the chair, the paper read was on "The Electric Street Railway System of Montreal, Canada," by Mr. G. C. Cuningham, M.I.C.E.

The author traced the rapid development in Canada and the United States of the application of electricity to street railways. In the United States in 1888 there were about 20 electrical roads in operation, having a total of 80 miles of track, and working 90 motorcars, while there were now 10,363 miles of track, on which were operated over 40,000 motorcars. While this had been the progress in the United States, Canada had not been slow to adopt a system that was manifestly so convenient for the public. Montreal, Toronto, Hamilton, Ottawa, Winnipeg, Brantford, Niagara Falls, and other places had their electric systems either complete or in process of construction. Almost all the lines were constructed on the overhead trolley-wire system.

In Montreal the electric street railways comprised 74 miles of single line, laid on 41½ miles of streets. A daily service of 140 motorcars and about 50 trail cars was now running. The gradients were in many cases very severe. On the streets running at right angles to the St. Lawrence River there was a continuous rise in most instances, and short sections had gradients of 1 in 10, and even 1 in 8. These gradients were a severe test for the motorcars, but they were overcome successfully, and caused little difficulty.

The ordinary rail adopted was $6\frac{9}{16}$in. in height, and weighed 72lb. per yard. The rails were laid on a foundation of concrete, or embedded in it, according as block pavement or asphalte was used for the roads. The rails were constructed in complete electrical continuity, and where they passed the power station they were directly connected by copper wiring to the generators. Bond-wires were riveted into the web at each joint. To still further improve the return circuit, track return wires of the same size, 0·460in. in diameter, as the line feeders were riveted into the web at various points and carried back to the generators directly by overhead insulated copper wires. At first earth returns had been used, the rails being connected by copper wire to cast-iron car-wheels buried between 7ft. and 8ft. in the soil; but considerable electrolytic action was found to be set up between the earth and gas or water pipes. It was determined not to use the ground for this purpose, and to construct a complete metallic return.

The trolley wire used throughout the system was of bare copper, 0·365in. in diameter, carrying a safe current of about 440 amperes. It was suspended from poles between 110ft. and 120ft. apart at the kerb line on either side of the street, at a height of between 18ft. and 20ft. over the centre of each track. In some instances the trolley wire was carried by a central line of posts placed between the double tracks. The current had been at first supplied to the trolley wires connected in one continuous system; but this was now divided into various independent sections, so that trouble on any one was felt there only, and did not affect the others. Each section was fed directly from the power station by feed wires, and had its own system of return wires. The feed wire and return wire mostly used was 0·460in. in diameter, but within a three-quarter mile radius of the power station heavier insulated cables were inserted, about 1in. in diameter, carrying a safe current of about 600 amperes. Ten such wires led from the power station, and 10 others of same size acted as return wires, allowing for a total output from the power station of 6,000 amperes. The difference of potential maintained at the generators was 550 volts.

The boiler-house and engine-room were placed fairly centrally to the system, and near to the Lachine Canal, whence water was obtained for condensing purposes, and to the coal wharves. There were 15 Lancashire boilers, each 28ft. long by 7ft. in diameter, with double furnaces. They developed each 300 h.p., and carried a working pressure of 125lb. per square inch. The gases from the furnaces, after passing through the boiler flues, returned under the boilers and along their sides to the main flue. They then passed, at a temperature of between 439deg. F. and 480deg. F., into Green economisers placed on each side of the chimney, which heated the feed water to about 260deg. F. The temperature of the gases entering the chimney was between 225deg. F. and 250deg. F. The feed water was obtained from the condensing water, and entered the economisers at an average temperature of 90deg. F. The fuel used was bituminous coal from the Cape Breton mines, of an evaporative power of 6½lb. of water per pound of coal.

The engine and dynamo room was 235ft. long by 89ft. wide. There were six horizontal cross-compound condensing engines developing 600 h.p. each, with a boiler pressure of 125lb. per square inch. The cylinders were 24in. and 48in. in diameter, and steam-jacketed, with Corliss valves. The diameter of driving wheel was 22ft., its peripheral velocity at 70 revolutions per minute being nearly 4,900ft. per minute. The total weight of each engine was 85 tons. The engines were placed in a row next to the boiler-house, 26ft. from centre to centre, on foundations of cement concrete and brick in cement. Each of the first three engines drove four Edison generators, developing 200 kilowatts apiece. The driving wheels were double-crowned, and carried two pairs of belts, driving 41in. pulleys, fixed on the armature shaft of the generator. The three remaining engines drove each a pair of multipolar generators by one 52in. belt on one pulley, 48in. in diameter. The two generators were mounted on the same bedplate, with the pulley between them. The armature shaft and the pulley shaft were in alignment, and were connected by two friction clutches. By this means the generators could be driven together or separately. The generators were supported on a continuous length of foundation wall built in brick and cement, and sufficiently massive to be free from vibration.

The rolling-stock equipment in the summer amounted to 163 motorcars; in winter it was 145 closed cars with double motors, and 14 snow-sweepers with triple motors. There

Digitized by Google

were besides, 53 open trail cars and 60 closed trail cars belonging to the former horse system.

The motors developed 25 h.p. or 30 h.p. each, and were all of the single-reduction type, the ratio of the pinion to the gear-wheel being generally about 4 to 1. The average speed of the cars was about 7½ miles per hour. Electric snow-sweepers, 18ft. long, carried on two pairs of 33in. wheels, were used. To each axle was geared a 30-h.p. motor, a third motor being placed in the car to drive the rotatory brooms.

The cost of working for July, 1895, was almost exactly 3¾d. per car mile, and that of the power was less than ½d. per car mile. For the year ending September, 1895, the cost was 5⅓d. per car mile, the average cost of power being slightly under ¾d. per car mile.

In an appendix particulars were given as to the amount of coal consumed and electrical energy developed at the William-street power station, with details of the operation of the system during the past four years.

THE TIME-RATE OF GROWTH OF MAGNETISATION OF IRON AND ITS IMPORTANCE TO THE ELECTRICAL ENGINEER.*

BY ERNEST WILSON.

The permanent magnet, or loadstone, has been familiar to mankind from early times, and is at the present very useful to the electrician. Volta, about a century since, marked an epoch in the science of electricity by his discovery of the cell now known as the "voltaic" cell. It consists simply of two plates, one of copper and the other of zinc, dipping into brine or dilute sulphuric acid, but not touching one another. A copper wire is soldered to each plate, and when the wires are touched together they are more or less heated; in the process, energy is transferred from the cell to the wire by the agency of what we call the electric current. Many different forms of primary battery have been devised since Volta's time, not to mention the storage cell.

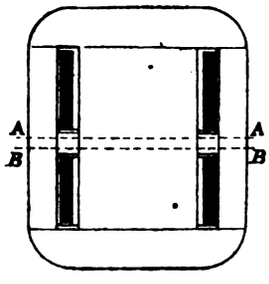

FIG. 1.

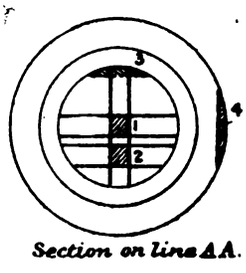

FIG. 2.

Soon after Oersted's discovery of the action of the electric current upon permanent magnets, Arago and Davy independently discovered how to magnetise iron by causing an electric current to circulate round an iron bar in spiral coils of insulated wire wound on the bar. If the iron be very soft—wrought iron, for instance—it will only be strongly magnetised when the current passes, and such an arrangement is known as an "electromagnet"—a name due to Sturgeon, who early constructed powerful electromagnets. The electromagnet is familiar to almost everybody nowadays. One meets with it in electric bells, telephones, dynamo-electric machines, arc lamps, and in a variety of other cases.

It is not necessary to dwell long upon the discoveries of Faraday in electromagnetism, which are the foundation of the modern dynamo—a machine which enables us to dispense with batteries for the purpose of producing electric currents, and converts mechanical energy directly into electrical energy. But I particularly wish you to note that in 1831 Faraday discovered that electric currents can be induced in a closed circuit—a copper wire, for instance, joined on itself—by moving magnets near it, or, what comes to the same thing, by changing the magnetism within it.

Let us return to our electromagnet. We have seen that when an electric current is passed through the copper wire wound on the magnet, the iron becomes magnetised, and is capable of exhibiting the same properties as permanent magnets. We have here on the table an electromagnet of ordinary form, with an iron core 4in. diameter.†

Downstairs in the engine-room there is another of different construction, having a core 12in. diameter. This larger magnet is shown in Figs. 1 and 2.* It consists of the central core, which has the copper coils wound on it for the purpose of magnetising it, and to complete the magnetic circuit a slab of iron, top and bottom, and a ring of iron concentric with the core.

Suppose, now, that either of these magnets is magnetised by passing an electric current through the copper coils wound on them, and that by means of a reversing switch we suddenly change over the direction of the current in the coil and have sufficient battery power to compel it to speedily attain a steady value, equal and opposite to that which it had before reversal took place. Fig. 3 shows the arrangement of apparatus by means of which this can be accomplished.

If the core be solid, as is the case in our magnets, what we find is, that on reversal of current the magnetism of the interior of the core becomes reversed in direction, but at a later time than the magnetism near the surface; and that this time, other things being equal, is greater in the 12in. magnet than in the 4in. magnet. In order to demonstrate this time effect to you we have bedded near the centre of each core a small exploring coil which is connected to a D'Arsonval galvanometer. Also near or on the surface of each magnet we have another coil connected to another D'Arsonval galvanometer. These instruments are made by Mr. R. W. Paul, Hatton-garden, London.

The bedding of these coils is a little differently carried out in the two cases. In the 12in. magnet, holes are drilled through the core in a plane at right angles to its axis midway between its ends, and by means of hooks insulated wires are threaded through these holes so as to enclose a small sample area at the centre; the outer coil in this case only encloses a sample area near the surface. This is shown in Fig. 2; the respective areas are numbered 1 and 3.

In the 4in. magnet on the table the central coil surrounds a rod of the iron, which, after being wound with the coil, was

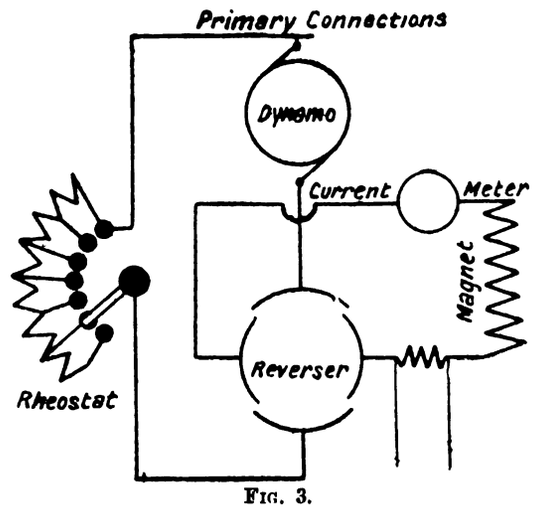

FIG. 3.

forced into a tube of the iron by means of hydraulic pressure, the ends of the coil being brought out to terminals at each end. The coil on the surface is simply wound round the magnet.

We have said that a D'Arsonval galvanometer completes the circuit of each exploring coil, and the deflection of the spot of light reflected from the mirror of the instrument tells us what is going on within the particular coil—that is to say, if we change the magnetism within the coil we shall induce, as Faraday found, an electric current in the circuit of the coil and galvanometer which deflects the needle; so that when the deflection is great we know that the time-rate of change of magnetism within the coil is also relatively great. These D'Arsonval galvanometers act, then, as a kind of eye-piece, by means of which we can see what is going on at the centre of the core and at the surface of the core at any time.

Let us take the 4in. magnet first. You note there are three spots of light on the screen. The top spot tells us what is going on in the innermost coil; the intermediate spot tells us about the outer coil near the surface of the core; and the bottom spot is in connection with the current which magnetises the magnet. What we shall note is this: When the reversal of current takes place, the bottom and intermediate spots will be immediately deflected, showing that the current is almost immediately totally reversed, and the change of magnetism occurs at once in the outermost coil. After a lapse of time the top spot begins to move, and shows by its maximum elongation when the rate of change in magnetism is a maximum for the innermost coil.

The same remarks refer to the large magnet, but we shall find that the time between reversal of current and when the

Digitized by Google

innermost coil experiences its maximum rate of change is smaller in the case of the 4in. magnet than in the 12in. magnet, the ratio being about 1 : 9. We shall further note that if the reversals are slowly and continuously performed, the innermost coil is not seriously disturbed, owing, as we shall presently see, to the shielding action of induced electric currents rendering the interior of the core practically useless for the purpose of magnetic change.

These time effects can also be shown by curves which have been recorded by means of photography on a plate moving at an appropriate speed before the spot of light. In Fig. 4 are two curves obtained from the innermost coil in the case of the two magnets—No. 1 in the 4in. and No. 2 in the 12in. Horizontally we have time in seconds ; vertically, the deflection of the instrument. These represent graphically what we have seen on the screen. The maxima occur at 6 and 59 seconds, the magnetising forces (H) being 11 and 16 respectively. The apparatus for recording these curves is on the table, but I do not wish to take up time on its explanation. It was made by Mr. W. Groves, Bolsover-street, London.

We have next to consider the cause of this marked effect and how it depends upon the magnets used. Roughly stated, the reason is that the iron of the core itself is a fairly good conductor of electricity, and it is solid: therefore, when the changes in magnetism begin on the outside of the core, they immediately set up opposing electric currents in the iron of the core itself, just as Faraday showed 65 years ago, only that iron is the conductor instead of copper. These currents, as they die out, on account of the magnetism being established in its reversed direction, allow a further penetration of magnetisation. This goes on from point to point until the centre is reached, and the reversed magnetism is fully established over the whole of the core. Now, the time taken to accomplish this process of reversal is intimately connected for a given magnet with the

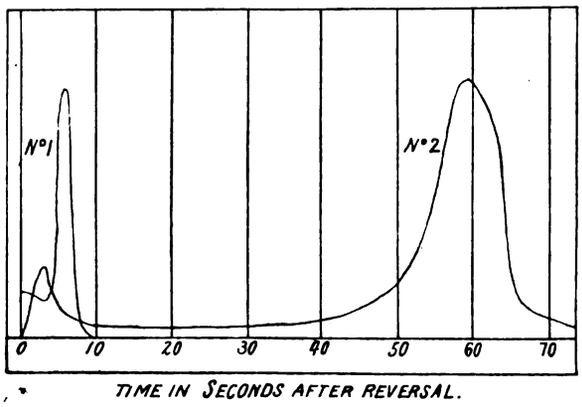

FIG. 4.

curve of magnetisation of the material, and it is not my intention to enter into a full explanation. But this is certain, and the experiments just made have fairly well shown it to be, so that if we compare two magnets similar in every respect then, if the external magnetising forces are the same in the two, similar magnetic events will happen, but at times after reversal varying as the square of their linear dimensions—that is, in our 12in. magnet the times are nine times those in our 4in. magnet. We infer from this that if we go on reducing the diameter of the bar we can make the times as short as we please—that is to say, if our 12in. core were not solid, but composed of a number of small cylinders or wires insulated from one another, and each 1-25th part of an inch diameter, everything would happen exactly as we have seen, but 90,000 times as quickly. If a non-conductor of electricity having the magnetic properties of iron could be found, there would be no necessity for subdivision in order to prevent induced currents.

I now come to the importance of this time-rate of change of magnetisation to the electrical engineer. Suppose, for a moment, that we could not prevent these induced electric currents in the iron of our core. This would mean that all direct-current dynamos and alternate-current transformers would be rendered useless, and we should be thrown back upon alternate-current machines without iron in the armature, and have to use rectifiers for direct or intermittent currents.

The fact is, that when we reverse our magnetising current, and eventually the magnetism of the whole core, work is done upon the magnet by the magnetising current other than that required to heat the copper coils. If we subdivide the core to such an extent as to practically annul the induced electric currents about which we have been speaking, there would still be a dissipation of energy in the core due to what is known as magnetic hysteresis ; but if the core be solid, the induced currents become a very serious matter, and represent energy which is dissipated and goes to heat the core. We have here a solid ring of soft iron—that is, it is not subdivided so as to stop electric currents induced within it, and at present it is quite cool. We now pass an alternating current round the magnetising coils wound on it so as to reverse the magnetism of the iron about 50 times per second. We find that it speedily becomes heated, partly owing to magnetic hysteresis, it is true, but almost wholly from induced currents. If it had consisted of a bundle of iron wires, the heating would have been in the same time almost imperceptible. It is fortunate for electrical engineers that by subdivision of iron in the form of thin wires or plates, the induced current can be kept at such a magnitude that its heating effect in dynamo-electric machinery is not more troublesome than the unavoidable heating due to magnetic hysteresis, which is a property peculiar to the material, and cannot be suppressed.

In addition to this dissipation of energy we have the shielding action of these induced currents, which renders the centre of solid iron cores or wires practically useless for the purpose of change of magnetism in the case of alternating currents of sufficiently high frequency. Take the 4in. magnet on the table. If we pass an alternating current through its magnetising coils having a frequency of 1/20—that is, the current is alternately positive and negative, and makes a complete reversal in 10 seconds—only the outside portion of the core is really useful, the centre being screened by the induced currents. With this frequency, a tube would be practically as useful as the solid core, the external diameter being the same. This is the same thing as stating that in the case of a soft iron wire one millimetre in diameter only the outside layers are really useful if the frequency be 500.

In conclusion, I wish to express my thanks to Dr. Hopkinson for allowing me to use his large magnet downstairs. In fact, the whole of this apparatus is the same as was used by him before the Royal Society, Royal Institution, and Institution of Electrical Engineers. The experiments have been arranged and carried out by my friends and colleagues, Messrs. Cobb, Evans, Shawcross, Welbourn, and Keigwin ; you will, I am sure, agree with me that they have done their work well, and that they deserve our best thanks.

THE TELEPHONE QUESTION.*

BY ALFRED R. BENNETT, M.I.E.E.

(Continued from page 185.)

When the granting of a license continued to be urged, the Postmaster-General spoke of the evils which he was advised would result from the existence of two separate exchanges in the same district or town, although experience in competition, which has not been wanting even in the United Kingdom, failed to bear out his assertions that it was detrimental to the public interests. He said that the Post Office itself had reserved the right to compete in any town or district in which the service was (according to the Post Office and not to the public) unsatisfactory. But such possible Post Office competition is nothing better than a mere pretext intended to allow the existing position of things to continue, as the Post Offices charges for telephone exchange communication are considerably higher than those of the National Telephone Company itself, so that Post Office competition affords no sort of remedy to those who consider the company's charges excessive. Besides, the Post Office has demonstrated its inability to compete with the National Telephone Company. It has endeavoured to do so in many towns and districts, but with the solitary exception of Newcastle-on-Tyne, where it obtained a strong footing before the Company commenced business, the results have been in the highest degree disappointing, so much so that in several places the Post Office exchanges have ceased to exist, even in face of such opposition as was afforded by the National Telephone Company with arrangements which the Post Office engineers have always alleged to be technically inferior to their own. The offer of Post Office competition, therefore, as a remedy in places where dissatisfaction exists with the company's service is but a sorry jest. Before the late Select Committee on the Telephone Service the chairman of the National Telephone Company stated several times that his company was the agent and partner of the Post Office in the telephone business. There is no doubt that he was to a large extent justified in saying this, and that the Post Office officials have no intention to do anything which will interfere with the virtual monopoly at present possessed by that company.

Before the same Select Committee the National Telephone Company professed to be convinced that competition was no longer possible because its license will expire in 16 years from the present time, in 1911, and it is assumed that any fresh licenses which may be issued by the Post Office would be made terminable at the same time. The resulting tenure would be so brief that Mr. Forbes, on behalf of the company, said that it would be absolutely impossible for any company or municipality proposing to compete with it to raise the necessary capital. Such seasonably sceptical views are not uncommon on the part

* Paper read before the East of Scotland Engineering Association at Edinburgh, February 5, 1896.

Digitized by Google

of chairmen of companies threatened with opposition. For instance, Sir Edward Watkin, chairman of the Manchester, Sheffield, and Lincolnshire Railway Company, predicted (see *Engineer*, August 6, 1886) that the Manchester Ship Canal would never be made, and that for a very simple reason—namely, that the necessary capital would never be raised.

Events have shown that Sir Edward Watkin was wrong, and Mr. Forbes's views in regard to the raising of capital for competing telephone exchanges were not shared by the witnesses who appeared for the Glasgow Corporation; but the assertion was repeated again and again, and apparently accepted by the Post Office officials as conclusive.

No doubt, if a company proposed to raise capital in the ordinary way for the purpose of erecting a competing system which could not have a longer life than 16 years, the task would be a difficult one; but the fact must not be lost sight of that if such a competing company erected a really good system with all modern appliances, the Post Office would be practically compelled to purchase it for at least its actual cost in the event of the license being recalled after 16 years. Then, as the Glasgow witnesses pointed out, a common good fund exists in that town which could be used for the purpose of constructing an exchange; and abroad the rates are used for the purpose in places where municipal exchanges exist, with results beneficial to the ratepayers, inasmuch as good profits are always earned. But a company might not be able to raise capital; the right of the Glasgow Corporation to use its common good fund for such a purpose might be challenged, and the Town Council might not obtain the necessary permission to use the rates for the creation of a telephone exchange. How, then, could the necessary capital for competition be obtained? Very easily, and in a manner which that, best of all tests, experience, has shown to be perfectly successful.

In several foreign countries the capital necessary for the construction of telephone exchanges has been raised by inviting those who desire to enjoy the benefits of telephonic communication to pay an amount down on their being accepted as members of the exchange, this payment down being apart from, and supplementary to, the ordinary annual subscription, which is payable in advance. Continental experience shows conclusively that telephone exchange lines with their necessary instruments do not cost more to construct than £10 or £12 each, even in such a large city as Christiania, and even when the cost of trunk lines connecting with neighbouring towns is included. Assume the case of a company or municipality wishing to construct an exchange on this system. The annual subscription would be fixed in accordance with the population of the town—in Christiania, it is £4. 8s. 11d.; in Trondhjem, it averages £2. 14s. 4d.; in Rotterdam, according to the tariff of the new exchange now being constructed for the Rotterdam Town Council, it is £6. 3s. 5d. It is desirable to have in hand at least £10 for each subscriber to be joined up, to provide which each intending subscriber would be asked to pay one year's subscription in advance, together with a contribution towards the cost of his line and apparatus. In this country a town of the size of Christiania could be telephoned at a profit for a subscription of £5. 5s. per annum, and one of the size of Trondhjem for £4. 10s. per annum. In a town of 100,000 inhabitants the necessary subscription would be £4. 15s., and in one of a population of 150,000, £5 In the case of a company or town council wishing to telephone a town of from 100,000 to 150,000 inhabitants on the plan referred to, intending subscribers would be asked to pay one year's subscription in advance—namely, £5—and either to contribute a special sum of £7, or to purchase a £7 share in the undertaking. These two sums together amount to £12, which would be sufficient to construct the line, put in the instrument, and provide the necessary switching apparatus at the exchange. As this would be done in the case of every subscriber, each man would bring the cost of his line with him, and there would be no occasion to go to the public for capital, or, in the case of a town council, to borrow or to call upon the ratepayers for any advance. It may be said that when this is done the company will have to provide for the first year's working expenses before the second annual subscription becomes due. If the amounts paid down by the subscribers in advance are not sufficient to cover this item, which in the case of a new exchange is a very insignificant one, the company could borrow money on the plant already erected, and so make good any deficiency, the borrowed money being made a first charge on the profits.

Edinburgh, with Leith, Granton, Portobello, Musselburgh, Dalkeith, etc., contains about 365,000 inhabitants. A metallic-circuit exchange comprising the latest improvements could be constructed at a cost of £16 per line, and such an exchange would be worked at a profit on a subscription of £5. 10s. per annum. The original payment by intending subscribers would be £5. 10s. + £10. 10s. = £16.

If we had to deal with towns of the largest size, such as Glasgow, Liverpool, or Manchester, the cost of the lines would be about £14, and the annual subscription necessary to work at a profit would be £5. 15s. The subscriber's original payment in this case would have to be £11. 5s. + £5. 15s. = £17.

It may be said that to call upon the subscribers to pay such an amount down as (in the case of Edinburgh) £16 would be to make too large a demand on their pockets, but when it is considered that the ordinary subscriber now pays the existing company £10 per annum in advance, whereas by the proposed plan he would pay £16 once, and only £5. 10s. per annum for all time thereafter, it will be seen that this objection is not a very weighty one. In four years he would pay only £32. 10s., instead of £40 as at present; and in five years £38, instead of £50. With such a system the possible recall of the license in 16 years possesses no importance: it would pay if the license lasted only three or four years. In that time the subscribers would have saved money on their annual payments apart from the value of the exchange, which would, nevertheless, remain their property. Besides, a subscription of £5. 10s. in Edinburgh would yield a handsome profit annually, even after paying the Post Office royalty, so that a company would have funds on its hands to dispose of in some shape or form. If shares were accepted in return for the contribution, each subscriber would be a shareholder, too, and would enjoy an annual dividend. Or, as is done by some of the Swedish, Norwegian, and Danish companies, the profit could be used for the purpose of reducing the amounts of the subscriptions instead of being paid away as ordinary dividends. It must not for an instant be assumed that an exchange provided in this way need be of the cheap and nasty order. By no means. Metallic circuits for the lines, the most modern apparatus for the instruments, and all appliances of the best sort could be provided for the sum named.

Advocates of the existing state of things will probably say that such a scheme is impracticable, and that people will not pay money down. The answer to that is that it is done in many places abroad, and what foreigners perceive to be a reasonable arrangement will not fail to recommend itself to the inhabitants of the United Kingdom. The General Telephone Company of Stockholm, which possesses more than 10,000 subscribers in the city of Stockholm and its immediate suburbs alone, is and has always been conducted on this plan. If 10,000 persons in Stockholm have been able to pay money down in the shape proposed, there cannot be anything very serious to urge against its feasibility. The plan, besides being practised in Sweden, Norway, and Denmark, has been very successful in the Grand Duchy of Finland, the telephonic exploitation of which is in the hands of companies and co-operative societies. The Governments of Austria and Roumania require their subscribers to find the capital for the construction of their lines; the French Government does the same except in Paris and Lyons; and the Luxemburg Government also brings the plan into use in certain specific cases. It is likewise well known that companies in the United States have built telephone exchanges and constructed trunk lines with no other capital than that afforded by the payment in advance of the bare subscriptions for one year. Besides, should the payment of the contribution in one sum be objected to, it would assuredly be possible to spread it over three or five years, as is done in Austria and some other countries. We may be sure, therefore, that it is quite practicable, if only the Post Office could be got to permit it, to start competing exchanges in the United Kingdom, or, at least, to establish exchanges in some of the very numerous towns and districts which are at present totally unprovided with telephonic communication without calling upon the general public to contribute any capital, without using the money of the ratepayers, and without drawing upon common good funds.

It is interesting to note that the opinions in favour of monopoly, and especially in favour of the monopoly of the National Telephone Company which are entertained by the permanent Post Office officials who appeared before the late Select Committee, and by whose influence the opinions of Postmasters-General are shaped, are not shared by all the Post Office authorities. It was admitted before the late Select Committee that the late Mr. Fawcett, one of the most distinguished Postmasters-General which we have possessed during the last few years, and the author of many beneficial reforms in the Post Office, was absolutely in favour of free competition in telephones. He thought that if the Post Office had anything better to offer to the public than that which could be obtained from private suppliers of telephone communication, then the public would adopt the Post Office plans and not those of the private competitors; if, on the other hand, the Post Office plans proved unacceptable, it was proof positive that they were not adapted to the needs of the community. The late Mr. Raikes, who was also a Postmaster-General capable of forming his own opinions, was likewise opposed to amalgamation taking place between the different licensed companies, as he looked upon monopoly as inimical, not only to the interests of the public, but to those of the Post Office also. The two gentlemen named were Postmasters-General, but their views are shared by members of the permanent staff. Mr. F. E. Baines, C.B., late Inspector-General of her Majesty's Mails, served forty years in the Post Office as an official, and during many years was the effective controller of the Post Office telegraphs. Mr. Baines, as is evidenced in his books "Forty Years at the Post Office" and "On the Track of the Mail Coach," takes an infinite

Digitized by Google

pride in the achievements of the Post Office, and such a man would be the last to favour free telephonic competition unless his experience convinced him that it is the only method calculated to fully develop the telephonic needs of the nation. It is therefore most interesting and instructive to find that Mr. Baines is absolutely opposed to those permanent officials who are the chief advocates of the National Telephone Company, and to the late Postmaster-General, Mr. Arnold Morley. The extracts from Baines's last book, which form an appendix to this paper, leave no doubt that the present advocacy of monoply within the Post Office is more an accident of individuals than of settled departmental conviction. It will be noted that Mr. Baines is satisfied that a £5 subscription is sufficient for local requirements, and that his estimates of the cost of erection and maintenance of telephone lines do not agree with those put forward by the Post Office witnesses before the late Select Committee, but are more consonant with the experience obtained by the Mutual Telephone Company, the Christiania Telephone Company, and other independent concerns. Major-General Webber, C.B., another Post Office engineer of long experience, to whom the construction of some of the chief routes of telegraphs in the country is due, is also totally opposed to the aims and estimates of the present officials.

Some of the evidence which was given before the late Select Committee calls for special consideration at the hands of municipalities and of telephone users. Mr. Forbes, speaking for the National Telephone Company, said that in about nine years' time the tenure remaining to the company will have become so short that it will no longer pay the company to invest capital in the further development of its system. This means, therefore, that if the Post Office and the National Telephone Company are allowed their own way no person or firm will be permitted to join a telephone exchange after the year 1904, because as the company's license expires in 1911 it would not be profitable to construct any more lines. Surely this threatened stoppage in development is a matter which ought to be taken into serious consideration by municipalities. Possibly it is a threat on the part of the company intended to force an extension of its license from the Post Office, but such an alternative is almost as grave as the former one, and the existence of the threat makes the date of the final telephonic crisis 1904 instead of 1911, and a correspondingly earlier solution is consequently called for.

(To be concluded.)

BOARD OF TRADE REGULATIONS.

The following are the regulations recently adopted by the Board of Trade under the Electric Lighting Acts of 1882 and 1888. They are classified under two headings—(A) for securing the safety of the public, and (B) for ensuring a proper and sufficient supply of electrical energy.

A.—REGULATIONS FOR SECURING THE SAFETY OF THE PUBLIC.

General.

Definitions.

In the following regulations—

The expression "the order" means the Order,

The expression "the undertakers" means the undertakers for the purposes of the order.

The expression "consumer's wires" means any electric lines on a consumer's premises which are connected with the service lines of the undertakers at the consumer's terminals.

The expression "aerial line" means any electric line which is placed above ground and in the open air.

The expression "pressure" means the difference of electrical potential between any two conductors through which a supply of energy is given, or between any part of either conductor and the earth; and—

(*a*) Where the conditions of the supply are such that the pressure may at any time exceed 500 volts if continuous, or 250 volts if alternating, but cannot exceed 3,000 volts, whether continuous or alternating, the supply shall be deemed a high-pressure supply;

(*b*) Where the conditions of the supply are such that the pressure may on either system exceed 3,000 volts, the supply shall be deemed an extra high-pressure supply.

The expressions "high pressure" and "extra high pressure" respectively are used in relation to electric lines, conductors, circuits, and apparatus, according to the conditions of the supply delivered through the same or particular portions thereof.

Where these regulations require any metallic body to be "efficiently connected with earth," it shall be connected with the general mass of earth in such manner as will ensure at all times an immediate and safe discharge of electrical energy.

Other expressions to which meanings are assigned in the order or in the above-mentioned Acts have the same respective meanings in these regulations.

Pressure of Supply to Consumers.

(1) The pressure of a supply delivered to any consumer shall not exceed 250 volts at any pair of terminals, except with the express approval of the Board of Trade. Such approval will only be given for special purposes, and on the joint application of the consumer and the undertakers, and the supply will be subject to such further regulations as the Board of Trade may from time to time prescribe.

Pressure of Supply to Transforming Apparatus.

(2) The pressure of a supply delivered to a transforming station or to transforming apparatus on a consumer's premises may exceed 250 volts, but shall not exceed the limits of high pressure.

Limitations of Extra High-Pressure Supply.

(3) An extra high-pressure supply shall not be given except to distributing stations, or other premises in the sole occupation of the undertakers, and with the written consent of the Board of Trade, and subject to such regulations and conditions as the Board of Trade may prescribe.

Maximum Current in Conductors.

(4) The maximum working current in any conductor shall not be sufficient to raise the temperature of the conductor or any part thereof to such an extent as to materially alter the physical condition or specific resistance of the insulating covering, if any, or in any case to raise such temperature to a greater extent than 30deg. F. The cross-sectional area and conductivity at joints must be sufficient to avoid local heating, and the joints must be protected against corrosion.

Minimum Size of Conductors.

(5) The sectional area of the conductor in any electric line laid or erected in any street after the date of these regulations shall not be less than the area of a circle of one-tenth of an inch diameter, and where the conductor is formed of a strand of wires each separate wire shall be as least as large as No. 20 standard wire gauge.

Specification of Insulating Material.

(6) All material used for insulating electric lines or apparatus shall be of the best quality, and thoroughly durable and efficient, having regard to the conditions of its use. Suitable provision shall be made for the protection of the insulating material against injury or removal.

If the protection so provided be wholly or partly metallic it shall be efficiently connected with earth.

Insulation Test of Electric Lines.

(7) Every main shall be tested for insulation after having been placed in position and before it is used for the purposes of supply, the testing pressure being at least 200 volts, and the undertakers shall duly record the results of the tests of each main or section of a main.

Maintenance of Insulation.

(8) The insulation of every complete circuit used for the supply of energy, including all machinery, apparatus, and devices forming part of, or in connection with, such circuit, shall be so maintained that the leakage current shall not under any conditions exceed one-thousandth part of the maximum supply current; and suitable means shall be provided for the immediate indication and localisation of leakage. Every leakage shall be remedied without delay.

Every such circuit shall be tested for insulation at least once in every week, and the undertakers shall duly record the results of the testings.

Provided that where the Board of Trade have approved of any part of any electric circuit being connected with earth, the provisions of this regulation shall not apply to that circuit so long as the connection with earth exists.

High-Pressure Conductors to be Covered.

(9) Every high-pressure conductor laid after the date of these regulations shall be continuously covered with insulating material to a thickness of not less than one-tenth part of an inch, and in cases where the extreme difference of potential in the circuit exceeds 2,000 volts, the thickness of insulating material shall not be less in inches or parts of an inch than the number obtained by dividing the number expressing the volts by 20,000.

Testing of Insulation of all parts of any High-Pressure Circuit.

(10) A high-pressure circuit shall not be brought into use unless the insulation of every part thereof has withstood the continuous application, during one hour, of pressure exceeding the maximum pressure to which it is intended to be subjected in use—that is to say, in the case of every electric line a pressure twice the said maximum pressure, and in the case of every machine, device, or apparatus, a pressure of 50 per cent. greater than the said maximum pressure.

The undertakers shall duly record the results of each test.

Quick-Acting Cut-Off for High-Pressure Lines, etc.

(11) Every high-pressure electric line, conductor, or other apparatus shall be protected by a suitable automatic quick-acting cut-off.

Provided that it shall not be incumbent upon the undertakers to provide such a cut-off for the outer conductor of a concentric

Digitized by Google

main which is, with the approval of the Board of Trade, efficiently connected with earth.

Transformers.

(12) In every case where a high-pressure supply is transformed for the purpose of supply to one or more consumers, some suitable automatic and quick-acting means shall be provided to protect the consumer's wires from any accidental contact with or leakage from the high-pressure system, either within or without the transforming apparatus.

Limit of Power in High-Pressure Electric Line.

(13) A high-pressure electric line shall not be used for the transmission of more than 300,000 watts, or in the case of an aerial line 50,000 watts, except with the consent in writing of the Board of Trade, and efficient means shall be provided to prevent this limit being at any time exceeded.

Protection from Lightning.

(14) Where any portion of any electric line or any support for an electric line is exposed in such a position as to be liable to injury from lightning, it shall be efficiently protected against such injury.

Accidents to be Reported.

(15) Where any accident by explosion or fire, or any other accident of such kind as to have caused or to be likely to have caused loss of life or personal injury has occurred at any part of any electric line or work, the undertakers shall give immediate notice thereof to the Board of Trade.

AERIAL LINES WHERE ERECTED WITH THE NECESSARY CONSENTS.

Maximum Intervals between Supports.

(16) Every aerial line shall be attached to supports at intervals not exceeding 200ft. where the direction of the line is straight, or 150ft. where the direction is curved, or where the line makes a horizontal angle at the point of support.

Supports, Construction and Erection of.

(17) Every support of an aerial line shall be of a durable material, and properly stayed against forces due to wind pressure, change of direction of the line, or unequal lengths of span. The factory of safety shall be for aerial lines and suspending wires at least 6, and for all other parts of the structure at least 12, taking the maximum possible wind pressure at 50lb. per square foot. No addition need be made for a possible accumulation of snow.

Every support if of metal shall be efficiently connected with earth.

Attachment of Aerial Lines.

(18) Aerial lines shall be connected to insulators, and shall be so guarded that they cannot fall away from the support. Conductors covered with insulating material shall not be attached to the insulators by uninsulated metal binders.

Height from Ground and Distance from Buildings, etc.

(19) An aerial line shall not in any part thereof be at a less height from the ground than 18ft.,* or where it crosses a street 30ft.,* or within 5ft. measured horizontally, or 7ft. measured vertically from any building or erection other than a support for the line, except where brought into a building for the purpose of supply.

Service Lines from Aerial Lines.

(20) Service lines from aerial lines shall be led as directly as possible to insulators firmly attached to some portion of the consumer's premises which is not accessible to any person without the use of a ladder or other special appliance, and from this point of attachment they shall be enclosed and protected in accordance with the subsequent regulations as to electric lines on the consumer's premises. Every portion of any service line which is outside a building, but is within 7ft. from the building, shall be completely enclosed in stout indiarubber tubing.

Angle of Crossing Thoroughfares.

(21) Where an aerial line crosses a street, the angle between the line and the direction of the street at the place of crossing shall not be less than 60deg., and the spans shall be as short as possible.

Crossing Wires, etc.

(22) Where an aerial line crosses, or is in proximity to any metallic substance, precautions shall be taken by the undertakers against the possibility of the line coming into contact with the metallic substance, or of the metallic substance coming into contact with the line by breakage or otherwise.

Suspending Wires.

(23) Every high-pressure aerial line shall be efficiently suspended by means of insulating ligaments to suspending wires, so that the weight of the line does not produce any sensible stress in the direction of its length. All suspending wires, if of iron or steel, shall be galvanised.

Discharge of Pressure in Case of Fire.

(24) In the case of any high-pressure aerial line exceeding one-half mile in total length, means shall be provided whereby the pressure may be discharged from any portion of the line erected over or alongside of any building or buildings without loss of time in case of fire or other emergency.

Maintenance.

(25) Every aerial line, including its supports and all the structural parts and electrical appliances and devices belonging to or connected with the line, shall be duly and efficiently supervised and maintained as regards both electrical and mechanical conditions.

Unused Aerial Lines to be Removed.

(26) An aerial line shall not be permitted to remain erected after it has ceased to be used for the supply of energy, unless the undertakers intend within a reasonable time again to take it into use.

ELECTRIC LINES OTHER THAN AERIAL LINES.

Construction of Receptacles for Electrical Lines.

(27) All conduits, pipes, casings, and street boxes used as receptacles for electric lines shall be constructed of durable material, and where laid under carriageways shall be of ample strength to prevent damage from heavy traffic; and reasonable means shall be taken by the undertakers to prevent accumulation of gas in such receptacles.

Crossing Pipes, etc.

(28) Where any electric line crosses, or is in proximity to, any metallic substance, special precautions shall be taken by the undertakers against the possibility of any electrical discharge to the metallic substance from the line or from any metal conduit pipe or casing enclosing the line.

Electric Continuity of Metal Conduits, Pipes, or Casing.

(29) All metal conduits, pipes, or casings containing any electric line shall be efficiently connected with earth; and shall be so jointed and connected across all street boxes and other openings as to make good electrical connection throughout their whole length.

Precautions Against Charging of Short Lengths of Pipe, etc.

(30) Where isolated lengths of metal conduit, pipe, or casing are used for the protection of any electric line at road crossings or similar positions, special precautions shall be taken to prevent the possibility of any electrical charging thereof.

Precautions to be Taken when Bare Conductors are Used.

(31) Where the conductors of electric lines placed in any conduit are not continuously covered with insulating material, they shall be secured in position, and no unfixed uninsulated material of a conducting nature shall be contained in the conduit. No such conductor shall be at a higher potential than 300 volts.

Adequate precautions shall also be taken to ensure that no accumulation of water shall take place in any part of the conduit, and to prevent any dangerous access of moisture to the conductors or the insulators.

In the case of any such electric lines laid in conduits after the date of these regulations, the insulators shall be so disposed that they can be readily inspected.

High-Pressure Lines Laid Above Ground.

(32) Every portion of any high-pressure electric line placed above the surface of the ground, or in any subway not in the sole occupation of the undertakers, shall be completely enclosed either in a tube of highly insulating material embedded in brickwork, masonry, or cement concrete, or in strong metal casing efficiently connected with earth.

High-Pressure Lines Laid in Proximity to Other Electric Lines or to the Surface of the Ground.

(33) Where any high-pressure electric line is laid beneath the surface of the ground efficient means shall be taken to render it impossible that the surface of the ground or any neighbouring electric line or conductor shall become charged by leakage from the high-pressure electric line.

Street Boxes.

(34) In addition to the provisions contained in regulation 27 as to the construction of receptacles for electric lines, the following regulations shall be observed with respect to the construction of street boxes.

(*a*) The covers of all street boxes shall be so secured that they cannot be opened except by means of a special appliance.

(*b*) The covers of all street boxes containing high-pressure apparatus other than cables shall be connected to strips of metal laid immediately underneath the adjacent roadway, and efficient means shall be taken to render it impossible that the covers or other exposed parts of these boxes, or any adjacent material forming the surface of the street, shall become electrically charged, whether by reason of leakage, defect, or otherwise.

(*c*) Where street boxes are used as transformer chambers, reasonable means shall be taken to prevent as far as possible any influx of water, either from the adjacent soil or by means of pipes; and in the case of any such street box exceeding one cubic yard in capacity, ample provision shall be made, by ventilation or otherwise, for the immediate escape of any gas which may by accident have obtained access to the box and for the prevention of danger from sparking.

(*d*) All street boxes shall be regularly inspected for the presence of gas, and if any influx or accumulation is discovered, the undertakers shall give immediate notice to the authority or company whose gas-mains are laid in the neighbourhood of the street box.

Transforming Stations.

(35) Transforming stations, or points in a system of distribution in which a high-pressure supply is transformed for the purpose of supply to consumers, and which are not on the consumer's premises, shall be established in suitable places which are in the sole occupation and charge of the undertakers,

* Note.—In the county of London 20ft. and 35ft.

Digitized by Google

CONSUMER'S PREMISES.

Responsibility of Undertakers for their Lines, etc., on Consumer's Premises.

(36) The undertakers shall be responsible for all electric lines, fittings, and apparatus belonging to them, or under their control, which may be upon a consumer's premises, being maintained in a safe condition and in all respects fit for supplying energy.

Fire Risks.

(37) In delivering the energy to a consumer's terminals the undertakers shall exercise all due precautions so as to avoid risk of causing fire on the premises.

Main Fuses or Disconnectors to be Provided in a Locked Receptacle.

(38) A suitable safety fuse or other automatic disconnector shall be inserted in each service line within a consumer's premises as close as possible to the point of entry, and contained within a suitable locked or sealed receptacle of fireproof construction, except in cases where the service line is protected by fuses in a street box.

Treatment of Electric Lines and Apparatus on Consumer's Premises.

(39) All electric lines and apparatus placed on a consumer's premises shall be highly insulated and thoroughly protected against injury to the insulation or access of moisture, and any metal forming part of the electric circuit shall not, unless efficiently connnected with earth, be exposed so that it can be touched. All electric lines shall be so fixed and protected as to prevent the possibility of electrical discharge to any adjacent metallic substance.

Transformers and High-Pressure Apparatus to be Enclosed in Metal.

(40) Where the general supply of energy is a high-pressure supply, and transforming apparatus is installed on a consumer's premises, the whole of the high-pressure service lines, conductors, and apparatus, including the transforming apparatus itself so far as they are on the consumer's premises, shall be completely enclosed in solid walls, or in strong metal casing efficiently connected with earth and securely fastened throughout.

Connection to Consumer not to be made where Leakage would result.

(41) The undertakers shall not connect the wires and fittings on a consumer's premises with their mains unless they are reasonably satisfied that the connection would not cause a leakage from those wires and fittings exceeding one ten-thousandth part of the maximum supply current to the premises; and where the undertakers decline to make such connection they shall serve upon the consumer a notice stating their reasons for so declining.

Discontinuance of Supply on Discovery of Leakage on Consumer's Premises.

(42) If the undertakers are reasonably satisfied, after making all proper examination by testing or otherwise, that a leakage exists at some part of a circuit of such extent as to be a source of danger, and that such leakage does not exist at any part of the circuit belonging to the undertakers, then and in such case any officer of the undertakers, duly authorised by them in writing, or, if the undertakers so require, an electric inspector, may, for the purpose of discovering whether the leakage exists at any part of a circuit within or upon any consumer's premises, by notice require the consumer at some reasonable time, after the service of the notice to permit him to inspect and test the wires and fittings belonging to the consumer and forming part of the circuit.

In any case where the undertakers require the services of an electric inspector under this regulation they shall pay him the prescribed fee.

If on such testing the officer or the electric inspector discovers a leakage from the consumer's wires exceeding one ten-thousandth part of the maximum supply current to the premises, or if the consumer does not give all due facilities for inspection and testing, the undertakers shall forthwith discontinue the supply of energy to the premises in question, giving immediate notice of the discontinuance to the consumer, and shall not recommence the supply until they are reasonably satisfied that the connection with earth has been removed. This regulation shall not affect any power contained in the order or otherwise enabling the undertakers to discontinue the supply.

Appeal to Electric Inspector.

(43) If any consumer is dissatisfied with the action of the undertakers in refusing to give or in discontinuing or in not recommencing the supply of energy to his premises, the wires and fittings of that consumer may, on his application and on payment of the prescribed fee, be tested for the existence of leakage by an electric inspector.

This regulation shall be endorsed on every notice given under the provisions of either of the two last preceding regulations.

ARC LIGHTING.

Arc Lamps to be Guarded.

(44) All arc lamps shall be so guarded as to prevent pieces of ignited carbon or broken glass falling from them, and shall not be used in situations where there is any danger of the presence of explosive dust or gas.

Height from Ground.

(45) Arc lamps used in any street for public lighting shall be so fixed as not to be in any part at a less height than 10ft. from the ground.

Cut-off Switch.

(46) Arc lamps used in any street for private lighting shall be fixed so as not to be in any part at a less height than 8ft. from the ground, and shall be so screened as to prevent risk of contact with persons. A cut-off switch, fixed in a suitable locked receptacle, shall be provided for every high-pressure arc lamp, and such switch shall be of such pattern and construction as will provide:

(*a*) That the lamp can by its means be entirely disconnected from the supply circuit;

(*b*) That the switch itself can be safely operated in the dark without special precautions; and

(*c*) That there shall be no danger of any injurious electrical arcing, sparking, or heating being caused by the operation of the switch.

Penalties for Default.

(47) If the undertakers make default in complying with any of the preceding regulations, they shall on conviction be liable to a penalty not exceeding £10 for every such default, and to a daily penalty not exceeding £10.

The recovery of a penalty under these regulations shall not affect the liability of the undertakers to make compensation in respect of any damage or injury which may be caused by reason of the default.

B.—REGULATIONS FOR SECURING A PROPER AND SUFFICIENT SUPPLY OF ELECTRICAL ENERGY.

Notice of Intention to Supply through Mains.

(1) Forty-eight hours at least before the undertakers are ready to commence to supply energy through any feeding, charging, or distributing main, they shall serve notice upon the local authority of their intention to commence such supply.

Undertakers to Provide Constant Supply.

(2) From and after the time when the undertakers commence to supply energy through any distributing main, they shall maintain a supply of sufficient power for the use of all the consumers for the time being entitled to be supplied from such main; and such supply shall, except so far as may be otherwise agreed upon from time to time between the local authority and the undertakers, be constantly maintained. Provided that, for the purposes of testing, or for any other purposes connected with the efficient working of the undertaking, the authority by whom the electric inspector is appointed may give permission to the undertakers to discontinue the supply at such intervals of time and for such periods as that authority may think expedient. When the supply is so discontinued, notice of such discontinuance, and of the probable duration thereof, shall be forthwith served upon the local authority.

Provisions as Regards Stoppage.

(3) The system of distributing mains shall be so arranged that in case it becomes necessary to stop the supply through any portion of a main for more than one hour for the purposes of repairs, or for any other reason, the stoppage of supply will in no case exceed in amount a maximum power of 200,000 watts, or extend to the premises of more than 80 consumers, and in the case of every stoppage for more than one hour reasonable notice shall be previously given by the undertakers to every consumer affected thereby except in cases of emergency.

Pressure in Mains During Supply.

(4) During the whole of the period when a supply of energy is required to be maintained by the undertakers in the distributing mains under the order and these regulations, it shall be maintained at a constant pressure in these regulations termed the "standard pressure," but the standard pressure may be different for different portions of the distributing mains. Provided that the undertakers shall be deemed to have complied with the requirements of this regulation so long as the pressure does not at any point vary more than 2 per cent. from the corresponding standard pressure in the case of a general supply at high pressure, or 3 per cent. in other cases, unless changes in pressure recur so frequently as to cause unsteadiness in the supply.

Fixing of Standard Pressure.

(5) The standard pressure shall be fixed by the undertakers, and notice of the amount of such standard pressure shall be given to the local authority before the undertakers commence to supply energy to consumers, and such standard pressure shall not be altered except by permission of the local authority, and upon such terms and conditions as the local authority may impose, and after public notice has been given during a period of one month in such manner as the local authority may require, of the intention of the undertakers to apply for permission to alter the same. The undertakers may appeal against any decision of the local authority under this regulation to the Board of Trade, whose decision shall be final.

Declared Pressure at Consumer's Terminals.

(6) Before commencing to give a supply of energy to any consumer, the undertakers shall declare to such consumer the constant pressure at which they propose to supply energy at his terminals. The pressure so declared at any pair of consumer's terminals shall not at any time be altered or departed from except in consequence of any authorised alteration of the corresponding standard pressure. In the case of a transformation of energy on the consumer's premises, the undertakers shall give the consumer the choice of a supply at either of two different pressures, one of which shall be approximately half the other, and in such case the pressure so chosen by the consumer shall be the declared constant pressure.

Provided that no change shall be made in the pressure of the

Digitized by Google

supply to any premises which at the date of these regulations are supplied with energy by the undertakers except with the consent of the consumer.

Variation of Pressure at Consumer's Terminals.

(7) The variation of pressure at any consumer's terminals shall not under any conditions of the supply which the consumer is entitled to receive exceed 4 per cent. from the declared constant pressure.

Penalty for Default.

(8) If the undertakers make default in complying with any of these regulations as to supply, they shall, subject to the provisions of the order, be liable on conviction to a penalty not exceeding £5 for every such default, and to a daily penalty not exceeding £5.

These regulations are made subject to the power of the Board of Trade to make such further or other regulations as they may think expedient; and nothing in these regulations shall be construed to authorise the undertakers to lay any electric line or work their undertaking otherwise than in accordance with the order and the principal Act, or to supply energy otherwise than by a system for the time being approved of by the Board of Trade under the order.

THE CHELTENHAM ACCIDENT.

The following is the report of Major Cardew to the Board of Trade as to the causes of the fatal accident in connection with the electric light supply of the Cheltenham Corporation:

I have the honour to report, for the information of the Board of Trade, that, in compliance with the instructions contained in your minute of the 3rd inst., I have held an enquiry into the cause of the death of John Pugh, mechanic, on the 16th ult., while employed by the Corporation of Cheltenham in carrying out some alterations in one of the transforming chambers used by this Corporation for the purposes of their electric light supply. The enquiry was held on the 15th inst. The following witnesses were examined—viz., Leicester Richards Lee, engineer; Richard Edwards, jointer; M. H. Kilgour, borough electrical engineer; Richard Cresswell, D.Ph., surgeon. They severally confirmed the evidence previously given by them at the coroner's inquest. I carefully examined the chamber in which the accident took place, and I also visited the generating station.

Account of Accident.—The circumstances of the case are, I find, as follow: The Corporation of Cheltenham supply electric energy by means of a high-pressure alternating current, at a constant pressure of 2,000 volts, which is reduced by means of transformers placed partly in transforming stations below the level of the street and partly on consumers' premises, to a pressure of 100 volts, for purposes of supply to consumers. The transforming stations are larger than those usually constructed for the purpose, and are in all respects suitable in construction. The arrangements within them consist, in addition to the transformers, of high-pressure and low-pressure switchboards for regulating purposes. The particular station in question contains an extra number of high-pressure switches, as from it is controlled the supply to another transforming station. The work upon which the party were engaged at the time of the accident was the erection of a low-pressure switchboard on the north wall, in a position closely adjacent to one of the high-pressure switchboards. The unfortunate man was at the time boring a hole in a wooden batten with a large gimlet at a distance of only about 4in. from the high-pressure switchboard, on which were fixed several switches with exposed metal surfaces charged to the full pressure of 2,000 volts. The conditions, in fact, were such that although it was possible to do the work without making contact with the charged metal, it required continual care and attention to avoid the fatal consequence of an unguarded movement. The danger was, I consider, almost equal to that of sending a man into a magazine full of loose powder with a lighted candle in his hand. From the evidence of the foreman under whom Pugh was employed it appears that the latter was decidedly careless by nature, and that before the accident happened he had been cautioned several times. An indiarubber mat had been provided as a protection to be used when working at the high-pressure switchboards, but had been moved away, probably by the men at work, as not being required, since they were not manipulating the electric circuits. Indiarubber gloves were also provided, but the use of these would certainly have been inconvenient. The accident appears to have been caused by Pugh in a moment of forgetfulness raising his left arm until it came, as it naturally would, into contact with the charged metal, in two places causing wounds as described by Dr. Cresswell, the current entering his body by this arm, and leaving it partly by his feet and partly by his right hand, assuming that he was grasping the gimlet at the time. The abrasions on the face were probably caused in his fall, either by a simple blow or a subsequent contact. Death appears to have been practically instantaneous.

Opinion and Recommendations.—In my opinion this accident is chiefly to be attributed to an error in judgment on the part of those responsible in allowing such work to be carried on in close proximity to highly-charged metal. It is too much to expect that any man, and especially an imperfectly educated man, should exercise such continual care over all the movements of his body as was necessary in this case when he is engaged upon work distracting his attention from the danger, and when the danger itself is not of a kind that appeals to the ordinary senses. I understand that had the electric pressure been switched off from the sub-station to enable the work to be done with safety, the supply to a few customers would have been interfered with to some extent. I ascertained, however, that the undertakers regularly stop supply altogether on Wednesdays for two hours in the middle of the day, and the work could have been carried out with absolute safety during this interval. The fact appears to be that the possibility of danger was unfortunately overlooked. Under ordinary conditions no work other than attention to the electrical circuits should be carried on in any transforming station when any apparatus contained therein is charged to a high pressure. In the second place, I consider that the switching arrangements on the high-pressure switchboards in use in this and other transforming stations are needlessly dangerous in that large surfaces of charged metal are exposed, which could easily be covered by solid insulating material, so as to render an accidental contact with them impossible. I was pleased to find that on the main switchboard at the generating station well-designed arrangements had been made for the guarding of all charged metal. Some similar arrangements should be carried out on the switchboards in the transforming stations. The necessity for some alteration in this respect is now fully recognised by the borough electrical engineer, who had prepared for my inspection a model of an insulating cap to partially cover the charged metal. It appeared to me, however, that the protection could be made more complete, and my suggestions are now, I understand, under consideration. Thirdly, I would suggest that in all the transforming stations a thoroughly insulated floor should be provided, as can easily be done at a small expense. The indiarubber mats at present used are probably effective, but they are easily displaced. They should be retained for use on the insulated floor as an additional precaution. There should also be in every case where it can be arranged a stout wooden rail or other division to separate off the portion of the chamber in which high-pressure apparatus is fixed.

Finally, the Board of Trade should, I consider, request the immediate attention of the Corporation of Cheltenham to the remarks and suggestions contained in this report. Those who undertake the supply of electrical energy at a pressure which involves the danger of sudden death from a cause so unnatural and so remote from human experience as the mere contact with a piece of metal, and who in their operations necessarily employ men of imperfect education, untrained to grasp abstract ideas, have a heavy moral responsibility for the safety of their employés. I feel confident that the Corporation of Cheltenham and their electrical engineer fully realise their responsibilities in this matter, and that they will spare no expense or exertion to prevent for the future any accident to their employés.

WHAT, WHEN, AND WHERE.

TO CORRESPONDENTS.

All Rights Reserved. *Secretaries and Managers of Companies are invited to furnish Notice of Meetings, Issue of New Shares, Installations, Contracts, and any information connected with Electrical Engineering which may be interesting to our readers. Inventors are informed that any account of their inventions submitted to us will receive our best consideration.*

All communications intended for the Editor should be addressed C. H. W. Biggs, *139-140, Salisbury Court, Fleet Street, London, E.C. Anonymous communications will not be noticed.*

TO ADVERTISERS.

Advertisements should be addressed to the Publisher, 139-140, Salisbury Court, Fleet Street, E.C., and should reach him not later than noon of Thursday. **Special Terms** *for a series can be arranged on application.*

"SITUATIONS VACANT" and "WANT PLACES" Advertisements will be charged at THREE WORDS for ONE PENNY with a MINIMUM charge of SIXPENCE.

BOUND VOLUMES.

Vol. XV. of new series of "The Electrical Engineer" can be had bound in blue cloth, gilt lettered, price 8s. 6d. Subscribers can have their own copies bound for 2s. 6d., or covers for binding can be obtained, price 2s.

IMPORTANT NOTICE.

The agents of a foreign Government are making enquiries with the view of placing orders in this country. The Editor of the *Electrical Engineer* and *Contract Journal* has been asked to supply a list of Government contractors, so far as all kinds of military stores are concerned. He would be glad if any firm desirous of being placed on the list would at once communicate with him, stating the materials they are prepared to supply. The only rule to be followed is that they must be contractors to our own Government. All military stores, entrenching tools, tents, cloth, yarn, ironmongery, etc., are in request.

PROMISES AND PERFORMANCES.

It is not a profitable undertaking to call attention to the fulfilment or otherwise of promises. Politicians, it is well known, are very careful when out of office to promise in language that cannot well be translated so as to mean anything definite. Canvassers when trying to induce customers to instal the electric light promise that the cost will not be greater than the cost for gas, but of course when the bills come in these promises have to be explained away. Promoters, when trying to get subscriptions, word prospectuses so that the prospect of dividends looks golden. But it is with none of these phases of business that we will now trouble about. There seems to be signs of progress in electric traction. It is not generally known, or has made little impression, that for twenty years or so after Faraday's discoveries the aim of every designer was to obtain a motor. They had their generator in the voltaic cell, and hoped by means of an electric motor to obtain a combination that would satisfactorily compete with steam. In 1841 a small book translated from the German was issued, under the title, "Steam Superseded—An account of the newly invented electromagnetic engine for the propulsion of locomotives, ships, mills, etc., and also applicable to the processes of spinning, turning, grinding, sawing, polishing, etc., and every species of mechanical movement." For fifty years the use of motors slumbered or slept. Why they failed in the early stages of electrical activity we know; why they do not progress faster now is hardly so well known. Fifty years and more ago we were promised these applications; the fulfilment of the promise is now in a small measure taking place. Knowing as we know the vast difference in cost between electrical energy generated in a battery and transformed into mechanical energy through a motor and such energy generated and transformed by means of a dynamo and motor, it is wonderful to read the aspirations of these old designers. Thus Stoehrer, of Leipsic, stated his conviction that he could get some forty-five horse-power to propel a train of wagons with the usual number of passengers from Leipsic to Dresden on the railroad at an expense of but six shillings, "whilst the expense at present (1841) is about five pounds sterling." About the same time Wagener, of Frankfort, constructed a machine somewhat on the same lines as that of Stoehrer, for which a reward of one hundred thousand florins was guaranteed him by the German Diet "as soon as the plan shall be carried out on a large scale." It would be interesting to know the after-course of Wagener's work; all we know is that "this execution on a large scale has, according to the latest accounts, succeeded most brilliantly, for a sawmill is at present (1841) worked by electromagnetism in Bavaria, and this new power has already realised the most sanguine expectations. A locomotive is also propelled by it." Did Wagener ever get his one hundred thousand florins, or what was really the result of his experiments? Stoehrer's name is common in the books, but what of Wagener? We think that sufficient has been said to prove that the future

Digitized by Google

of the electric motor was well foreseen in 1841 by these workers, and that they failed to realise success only for the lack of an economical generator. It is truly surprising to find a general credence that motor work is a thought or an accident of the last twenty years, instead of a knowledge that such work was the great aim of the men working in the early days of this electric era. They promised, but they failed to realise—they were looked upon as dreamers and failures; but we who live in this generation know that their dreams were destined to bear fruit, and therefore those among us who are dubbed dreamers and enthusiasts may take heart and comfort themselves with the idea that what does not come to pass now will be realised probably before the end of the next generation.

CORRESPONDENCE.

"One man's word is no man's word,
Justice needs that both be heard."

AUTOCARS.

SIR,—A prospectus of the Daimler Motor Company reached me the same day as it was announced that the Prince of Wales was riding in a self-propelled carriage at the Imperial Institute with two vice-presidents of the Motor-car Club, who were respectively a director and the engineer of this company. I further observe that my name appears in this prospectus in bold type, presumably as a kind of advertisement for obtaining money from the public. As to whether the prospects of this company and the value of its property are good or bad, I have nothing to say. This is purely a matter with which the financial Press has to deal, but from letters which I have received, as well as from personal remarks made to me, I learn that there is an impression that I am in some way connected with or interested in the Motorcar Club and the Daimler Motor Company, the two concerns being closely related to one another, so many names being common in both. It is a source of satisfaction to me to state that I am not connected with either in any way whatever.

The prominent part which I have taken from the start in the self-propelled traffic movement, and which has now been solved by Mr. Henry Chaplin's reception of the strong deputation which I had the honour of introducing to him a few days since, has no doubt led many to believe that I have some financial interest in the question, present or future. I am anxious to disabuse such an idea. Any part I have played in this matter has been done purely out of patriotism, not desiring to see our nation in a worse position than those on the Continent.—Yours, etc.,

DAVID SALOMONS.

Broomhill, Tunbridge Wells, February 15, 1896.

USEFUL ELECTRIC LAMPS.

SIR,—In your issue of the 16th inst. there is a letter from Mr. Sydney Baynes, who is the better credited among the initiated because he openly signs it and abjures the pen name.

So far, I feel that in these days of pushing business, in which it is evident that honesty of purpose will be only known as a name within the space of a decade, I am dealing with one who like myself is not *fin de siecle*.

But I do not think Mr. Baynes has carefully studied the tests which led to the correspondence, nor read the correspondence itself upon the subject. I do not deny that German firms can turn out good lamps, but I needs must veto those which have been imported and turned over to the trade as English lamps, because of a similarity as to the outline and general appearance. These lamps are put upon the market at such a low price as to render selection out of the question, since the margin of profit on the manufacture alone is too meagre to admit of any claim respecting quality or efficiency.

I should like to know from the advocates of foreign-made goods what Germany or any other European State has done in the genesis of the incandescent lamp. England is foremost, America follows suit, and the others simply add details of more or less importance. The Edison patent held its own in Germany as forcibly as here, but the constitution of the German law is somewhat different, insomuch as it neither retarded nor ruined trade.

Mr. Baynes must suspend his judgment until other and equally reliable public tests have proved the superiority of English-made lamps, and then he will, I am sure, confess that either the Germans wasted a splendid opportunity when we were perforce in bondage, or that they export bad lamps prohibited for home use by the commission on selection test.

Any way Mr. Baynes studies the question, whether with a clock, a photometer, and a wattmeter, on actual time, illumination, and current test, or from the general aspect of the case, he must admit that "English-made lamps are the best," and that any slight extra cost due to the better class of the workmanship is refunded a hundredfold within a week, by the saving of the current supplied.—Yours, etc.,

FREDK. WALKER.

SIR,—My letter, kindly inserted by you and signed "Fair Play," has called forth a reply of doubtful value over the signature "Fredk. Walker."

It is not my desire to enter into controversy with him on any point, still less do I intend to follow him into personalities; but I should feel obliged if you would kindly find room for the enclosed translation of an article published in the *Elektrotechnische Zeitschrift*, of Berlin, on the 6th inst., and which I think points to the root of the matter.—Yours, etc.,

FAIR PLAY.

Reprint from the "Elektrotechnische Zeitschrift" of Feb. 6, 1896.

From a well authenticated quarter a letter has reached us which draws attention to the campaign which English manufacturers of incandescent lamps are carrying on in their technical journals against German makes. In this letter we read, *inter alia*, "The report of the commission for the establishing of standards for use by incandescent lamp makers at the conference of representatives of electricity works is doing incalculable harm to the German industry in this article, as shown in the advertisements in English technical journals, which will certainly not fail in their object, especially in the face of current feeling.

"Although this is not the place to enter fully into the question itself, we may be allowed to observe that the mischief to this trade would not have occurred had this important question been decided at the proper time by the union of German members of the profession or by some other authoritative body. It should be a lesson for those who appear to meddle light-heartedly with matters respecting which the criticism should be left in the hands of those only who are thoroughly familiar with all the circumstances surrounding the subject.

"A large but not particularly prominent company in London, whose chief directors are Germans, makes use of a liberal translation of the above-mentioned report in order, evidently, to depreciate German lamps in the eyes of their *pseudo-compatriots*."

It is easy to understand the desire of English manufacturers to kill German competition. Under protection of a monopoly that rests upon those very patents which the holders themselves have successfully combated in other countries, the prices of lamps in England could be maintained at a point as high as they stood a year ago, which to-day are out of all proportion to the manufacturing cost if the lamps are turned out under the latest, most approved methods. These high prices have unquestionably opposed very considerable difficulties to the development of electric lighting in England. In Germany, meanwhile, under the influence of free competition, the manufacture has been carried on ceaselessly, and the methods of production have been so improved and simplified that a perfection has been attained which has not been surpassed in any single particular by the lamps made in any other country in the world. Thus it is but natural that the importation of German lamps should be highly *inconvenient* to English makers!

The representatives of electricity works certainly cannot have intended, when publishing their deliberations, to forge weapons against native productions, for their remarks and investigations were not confined to German lamps alone, but rather to incandescent lamps in general, imported from, *inter alia*, Austria, Holland, and Sweden.

It should, therefore, be an incentive to the determining of a *uniform standard* of comparison for all incandescent lamps. That the creation of such a standard should be left to the

Digitized by Google

discretion of the Union of German Technical Experts is wisely suggested in the above-mentioned letter, because in this union every department of the electrical profession is fully represented, from whose co-operation really fruitful results can be reasonably hoped for.

REVIEWS.

Dynamo-Electric Machinery. By SILVANUS P. THOMPSON, D Sc., B.A , F.R S E. and F. N. Spon.

The fifth edition of this manual is now before us, and we are glad to note that the usual custom of addition only has not been followed in revising the previous issues. On the other hand, a large amount of the old matter of the fourth edition has been cut out, and other elementary parts have been condensed to make room for new information. Thus, the total number of pages, which in the previous edition was 864, has been reduced to 835, and the number of plate illustrations has been reduced from 29 to 19. The result is a much more handy volume, and hence a more useful one. We would, however, suggest that more attention should be given to the cuttings from books, catalogues, and newspapers so largely incorporated in the text to ensure that the same terms are not used for totally different things, and also to explain contradictory statements. Thus, referring to the external armature type of direct-current machines manufactured in Germany, the information is volunteered that "the outer part of the windings are non-inductive or idle." Neither of these terms is in any way correctly applied, and both tend to confuse the student. The term "non-inductive" is particularly open to objection. In other places, where the matter has stood through several editions, we notice that the tendency to generalise has allowed several paragraphs to appear which practice would condemn. Thus, referring to a shunt dynamo, the author says: "For a set of lamps in series the power of a shunt dynamo to supply the needful current increases with the demands of the circuit, since any added resistance sends additional current round the shunt in which the field magnets are placed, and so makes the magnetic field more intense." If this paragraph is read literally, a shunt machine should be *sine quâ non* for series working. To understand it correctly, a reader must have a critical knowledge of the subject which, certainly is not possessed by the student. It is this want of a critical examination of the useful extracts from the writing of experts that this book is deficient. We should say that, as a collection of references likely to be useful to students, it is unrivalled, but not every writer on a given subject is qualified to give a decided opinion on that subject.

As an example of this we would refer to p. 368, where, in speaking of the magnetic flux density allowable in dynamos, we find at the head of a table of maximum value, the statement that "as a rule the higher flux densities are admissible in the larger sizes only." This statement is directly in opposition to the English practice, but is supported by an American author, whose theories the author states to be wrong. The list of Edison dynamos, given a few pages further on, also contradicts the statement. Again, in the new chapter on transformer design, the author gives a series of useful hints on the best methods of procedure in designing, which are culled from various sources, and then proceeds to generalise on the effect of alterations of frequency. He concludes that "if a transformer designed for a 2,000-volt circuit at 100 periods is used on a system at 50 periods, it ought to be rated at a lower voltage, say, as a 1,000-volt transformer, or else rewound." And, again, that "for a given total loss, the output of a given transformer is proportional to the frequency." Any maker's list would be enough to disprove these absurd statements, but the application of the formulæ and rules previously given is all that is required. The chapters dealing with alternators and their design are valuable, on account of the foreign machines illustrated and described. The sections of these alternating-current generators and motors will give the reader much information as to the Continental practice. One intricate piece of reasoning on p. 647 is worthy of note. Speaking of two alternators in parallel supplying lamps, we learn that they are really working in series with one another if the lamps are disconnected. Again, on p. 752, we find the author's opinion is that "the electric tension or stress to which the dielectric is subjected tending to pierce it, varies as the square of the volts." So we presume that a test at twice the normal voltage would result in four times the normal strain. Also, we suppose that a cable for 10,000 volts would require a thickness of insulation ten thousand times that for a 100-volt cable. If these faults had occurred in earlier editions only we should have refrained from referring to them, but their repetition demands notice. The illustrations throughout the book are well executed, and the plates at the end are worthy of special commendation.

INSTITUTION OF ELECTRICAL ENGINEERS.

At the meeting of this Institution on **Thursday, February 13**, the president (Dr. Hopkinson) in the chair,

The **Secretary** read the formal acknowledgment from the Secretary of State of the resolution of condolence on the death of Prince Henry of Battenberg passed by the Institution.

The discussion on the wiring question was then resumed.

Mr. Andrews, after acknowledging what had been said at the former meeting as to his share in the invention of concentric wiring, remarked that on its first introduction concentric wiring was opposed to the existing practice and was received with great opposition on the part of the insurance companies, who for the most part followed the Phœnix rules. That opposition, he was happy to say had now died out. He could not say that he approved of Mr. Mavor's proposals for the inspection of installations by the insurance offices, and he did not think that English contractors should be regarded with such distrust as had been suggested by the remarks of some of the speakers. After referring to the system to be adopted in Guildford, Mr. Andrews said that with an earthed concentric system a more perfect balance could be maintained than with three separate conductors. A wide introduction of concentric wiring would considerably reduce the service mains and joints, but the principal reduction would be in the reduction of the cost of interior wiring. Of course its introduction was dependent upon permission to earth the outer, but doing this would be a great advantage, as the course of any leakage current would be reduced. If there was a leakage in a house, it would be confined to that house. When he spoke of earthing he did not mean at one point only, but all along the system, though of course he did not advocate bare conductors. All the way from the dynamo to the lamp the outer conductor should be so close to the inner that an arc could not be established without blowing a fuse. The insulating material in concentric wiring should be substantial, but it need not be more than enough to prevent such a leakage as was detrimental in a commercial sense.

Mr. Wallis Jones remarked that, looking back on the progress of electric wiring since 1881, it would be found that they had passed through three periods—the stone age, the wooden age, and the iron age. He believed the present, the iron age, had come to stay. In the absence of moisture almost any system of wiring was good enough, but in the presence of damp wood casing was very uncertain. He had known a case in which the conductor, a nineteen-sixteens cable, had absolutely dissolved away owing to the action of moisture from a burst water-pipe. If a new building had to be wired on a two-wire system, there was nothing so good, he thought, as the interior insulated conduit system. The concentric wiring system elaborated by Mr. Mavor was a most admirable one in the case of an isolated plant, but imagined there would be difficulty in the way of applying it to finished buildings in a sightly manner unless with the hollow walls as used in Scotland. In a conduit system it was possible to draw in and out considerable lengths of wire, and 60ft. or 70ft. circuit runs from distributor points might be conveniently used. He believed, on the ground of expense, that the conduit might be improved by reducing its diameter, thereby saving the cutting away of chases in brickwork.

Mr. Addenbrooke, referring to the financial aspect of wiring, said that, assuming the central station and mains cost about £100 per kilowatt, then, taking a fair proportion of 8-c.p. and 16-c.p. lamps, this would light about 20. But there might safely be 40 wired, so that, put the wiring at £1 per lamp, it worked out £40 for lamps and wiring for every £100 for central station and mains. The question of wiring was therefore a most important one from a financial point of view, since it was greater than any other single item, such as boilers or engines. It would, he thought, be very difficult to make the progress that they wanted unless earthing the central wire was allowed. One of the great obstacles in the introduction of the electric light was the great cost of wiring houses. Landlords would not bear the expense, and tenants could not make them; consequently there were numbers of people who would gladly pay for the current, but who went without the electric light because of the initial expense. To perfect a new system, a great many branches of manufacture must be taken up, and this had deterred many people from attacking the question of producing something to supersede wooden casing. Moreover, people were afraid of a new system, if it confined them to getting their fittings from one firm.

Digitized by Google

As far as convenience went, he thought Mr. Mavor's system was the best, and having asked for estimates for wiring a steamer he had obtained two on the concentric system which were under those on the double-wire system. In reference to electrolysis, if the middle wire was earthed at the distributing point and not at the feeders, there would be under existing practice an outside difference of three volts. So that, halving this for the middle wire, and allowing for the house, they would be left with a fraction of a volt available for electrolysis—an amount which ought not to be sufficient to produce it.

Mr. Russell congratulated the readers of the papers upon their work, but would have liked to have had further figures from Mr. Bathurst on the subject of reducing the cost by his system Having had experience with plain iron tubes, he found that the bogies of rust and condensation had not existence. This made a good job, but could not compete with cheap work at 15s. per lamp. To greatly reduce the cost of wiring, they must have a new system entirely. He would be glad to see the formation of a class of registered wiremen something like the registered plumbers. That would give confidence to customers, raise prices, and give them all a better chance.

Prof. Ayrton said that he had some time ago worked out the question of what was an economical cross-section as apart from what was a safe one, and he had found that the economic gauge of wire was generally much greater than one that would be safe from anydanger of heating. He did not think that the average contractor realised that the bare cost of the insulated wire was a very small fraction of the sum charged for putting a number of lamps into a house. Take the extreme case, say, 10 16-c.p. lamps on the top storey of a house, and say it is necessary to carry the current 100ft. up to the lamps and 100ft. down again. Allowing a 2 per cent. drop of potential, the actual cost of vulcanised wire for those 10 lamps would be 12s. With a 1 per cent. drop it would cost 17s.—that is, the difference was 5s. Theoretically, 98-volt lamps might be used in the one case and 99-volt lamps in the other, so that 1 per cent. more would have to be paid for current with the 2 per cent. drop if the same amount of light was produced. On the basis of 1,000 hours per year and 6d. per unit this worked out about 3s., so that the thicker wire would pay for itself in less than two years. But in practice 100-volt lamps would be used, in which case the difference of a volt would make about 7 per cent. difference in the light, so that by paying 5s. more for the wire there would be a saving of 7 per cent. on 300s., the yearly bill for electric energy, or 21s. per annum. He had spent a good deal of time in endeavouring to work out the best drop from an economic point of view, and as a result found that it paid to put in as large a cross-section of copper as could be done without materially increasing the cost of labour. This result led to another one—namely, that a great number of fuses might be dispensed with. Showing a flexible wire intended to carry 0 6 ampere at 450 amperes per squre inch, Prof. Ayrton remarked that it had had 35 amperes through it without heating, so that it would be absolutely safe without any fuses if attached to wires on which there was anywhere a 15-ampere fuse. Such fuses as were used should be of the same kind, or, if not, they should be absolutely non-interchangeable. In conclusion, he might mention, in reference to what had been said by Mr. Russell, that a practical examination for wiremen had been started this year by the City and Guilds Institute.

Prof. Silvanus Thompson began by calling attention to the paragraph in Mr. Bathurst's paper: "If a defect occurs so that there is electrical contact between the conductor and the pipe, with two conductors in the pipe an unanticipated electrical condition prevails because one conductor is now of greater carrying capacity than the other, which has been increased by the capacity of the tube itself. Overheating of the intact conductor can now invite serious trouble at any point; also, that failure of insulation on one wire means that the voltage tending to break down the other is doubled, and the actual strain increased fourfold." Prof. Thompson remarked in reference to this that where there was a very high electrical resistance obtained by using a thin material of good quality, there was an advantage in lining the pipe and so obtaining a double insulation. Prof. Thompson described a method he had adopted in wiring his own house, where a flexible double-wire cable was produced by using lead covering. Prof. Thompson also contended that fuses in a ceiling rose were most objectionable, as it was impossible to get at them, and all fuses should be so made as to be replaceable without difficulty while the current was on. One disadvantage of systems in which the wires could not be taken out was that it was impossible to add materially to the number of lamps. In conclusion, reference had been made to the iron age as having come to say. There were some people who thought it was to be succeeded by the aluminium age. If so, by means of the new photography they would be able to inspect the joints and wires *in situ*.

Mr. Mavor, who stated that he would be unable to be present at the next meeting, when the discussion is to conclude, then replied upon it so far as it had gone. He thought the insurance companies were right in insisting on a high standard of insulation while wood casing was used, because it was only by exacting a very high standard that they could secure "good work of this bad kind." In reply to Mr. Geipel, he thought it one of the advantages of his system that it required a workman that could make a solder joint and that it could not be done by joiners. He protested against one of the illustrations in Mr. Bathurst's paper, which was a libel on concentric conductors. Mr. Langdon's suggestion as to inspection of installations by supply companies he did not agree with. It was not their business. Moreover, it left out the thousands of isolated installations. Mr. Swinton was mistaken in supposing that the contractor would require two staffs of workmen. There was nothing in his system that any man who could use a soldering bolt could not pick up in half an hour. Moreover, the expense for labour on the job was much reduced, and that, as they knew, was a kind of labour that was particularly difficult to supervise. The current capacity of the wire had little to do with the fuse. The fuse should be proportioned to the maximum current intended to be used. The danger was not general heating of the conductor, but heating at one point. It was advisable to limit the amount of current in any one conductor in a building. With reference to Mr. Antill's criticism on his curve of wiremen's employment, it represented Glasgow, and most of the work was in shops and offices, and would be finished in two or three weeks. As to earthing, it should, in his opinion, be done at the feeding points, and should be removable for testing purposes. He could not understand why some people wanted to keep drawing their wires in and out of tubes. In conclusion, he regretted that so long a time had elapsed since the papers had been read. Indeed, to judge from their speeches, some of the members seemed to have forgotten that they ever were read.

The discussion was then adjourned to February 27.

LEGAL INTELLIGENCE.

SOUTH STAFFORDSHIRE TRAMWAYS COMPANY.

In the Queen's Bench Division the action of the South Staffordshire Tramways Company *v.* Ebbsmith and Wain occupied the Lord Chief Justice and a special jury for five days, and was finished on Tuesday. The action was brought to recover damages from the defendants for fraudulent conspiracy while they occupied the fiduciary positions of solicitor and chairman respectively to the South Staffordshire and Birmingham District Steam Tramways Company, Limited, by which they had induced that company, whose property and rights were under an Act of 1889 taken over by the plaintiff company, to purchase from them certain unnecessary land and worthless patents; and to recover secret profits and moneys of the company used by the defendants in packing meetings of the shareholders; and for recission of the contracts for the purchase of the said land and patents.

The company was incorporated in May, 1882, with a nominal capital of £350 000, of which £260,000 was actually subscribed. There were also preference shares to the amount of £76,000, making the total capital £336,000 In addition to that the company raised about £30,000 in debentures. The defendant Mr. Ebbsmith was appointed local solicitor to the company in March 1882, and sole solicitor in March, 1887, which position he continued to hold till April, 1889, when he resigned his connection as solicitor, merely continuing as Parliamentary solicitor for the purpose of conducting a Bill through Parliament. The defendant Wain was appointed chairman in October, 1885, continuing in that capacity down to 1894. The defendant Ebbsmith in January, 1886, formed a company called the Dickinson Company, to which company he assigned his patents for a lifeguard, etc., receiving all the shares of the company in payment therefor, except the seven signatories' shares. It appeared that the defendant Mr. Ebbsmith, who had acquired 13 acres of land at Wednesbury for £1,000, transferred 2¾ acres of that land to the company for a consideration of £7,122. 10s. which with £100 for the assignment of the lease, and £91. 16s. for costs, made the figures in respect of the land £7,313. 6s. The plaintiffs' case was this was an extravagant profit, that no independent valuation was made of the land, which was not worth more than £700, and that the transaction was an abuse of the defendant's position as solicitor of the company. The plaintiffs also alleged that the meeting at which the resolutions for taking the land, etc., were passed was packed, a sum of £362 being expended in various ways, such as hire of saloon railway carriages, luncheons, etc As to the patents, the case for the plaintiffs was that too much money had been paid for the rights of the defendant Ebbsmith.

The defendant **Ebbsmith** denied that the circumstances connected with the sale of the Wednesbury property to the company were in any way kept secret. With regard to the patents, he bought the road and rail car from Dickinson. He thought it good, and did not know where it was made. There was no secrecy in the matter.

On behalf of the defendant Wain, **Mr. Kemp** submitted that the defendant had no fraudulent knowledge or intention.

The **Lord Chief Justice** having summed up, the jury found that in the matter of the sale of the land the defendants acted in concert and thereby defrauded the company, and that the damages in respect of that were £7,313, to which was to be added interest at 3½ per cent. from 1887. They also found that as regards the patents there was a conspiracy between Smith and Wain to obtain payment of sums for royalties, and that the charges made for the apparatus should have been sufficient to include royalties. On that head they assessed the damages at £2,150. As to the packed meeting, they found there was a misappropriation of the funds, and that £362 was to be given in regard to that, with interest at 3½ per cent. from the date of payment. Judgment was entered accordingly.

HOPKINSON'S GAUGES.

Last week Mr. Justice North, in the High Court of Justice, heard an action brought by Messrs J Hopkinson and Co., Limited, of Britannia Works, Huddersfield, and of Queen Victoria-street, London, jointly with Messrs. J Dewrance and Co., of Great Dover-street, London, engineers, to restrain the defendant, a

Digitized by Google

brassfounder, at Devonshire Brassworks, Keighley, from infringing the joint patent rights of the plaintiffs for the manufacture of improved water-gauges. Mr. R. W. Wallace, Q.C., and Mr. Arthur Pagett (instructed by Messrs. Learoyd and Co.) appeared for the plaintiffs. The defendant was perpetually restrained from continuing to infringe, ordered to withdraw all infringements from his customers and his advertisements, to deliver to the plaintiffs all infringing gauges, and to pay the costs of the action.

COMPANIES' MEETINGS AND REPORTS.

NEWCASTLE AND DISTRICT ELECTRIC LIGHTING COMPANY.

The annual meeting of this company was held at Newcastle last week, Mr. John D. Milburn, chairman of the directors, presiding.

The report has already been published, and the **Chairman**, in moving its adoption, said that it was gratifying to state that their output was still on the increase. They had issued no new shares because they required no extra money. They were keeping up a depreciation fund; they were fully alive to the value of it, and intended to continue it.

Sir B. C. Browne seconded, and the reports were adopted.

The **Chairman** moved that a dividend at the rate of 4 per cent. for the half-year ending December 31, making 6½ per cent. on the year, be paid.

Mr. J. B. Simpson seconded, and this was agreed to. It was decided that the directors' fees remain as before. Sir B. C. Browne and Colonel H. S. Dyer were re-elected directors; Messrs. Strachan and Co. were reappointed auditors.

WESTMINSTER ELECTRIC SUPPLY CORPORATION, LIMITED.

The ordinary general meeting of this Company was held at their offices, Eccleston-place, Belgravia, S.W., on Wednesday. In the absence (through illness) of the chairman of the Board (Right Hon. Lord Suffield, K.C.B.), Mr. James Heslop Powell presided.

In moving the adoption of the report and accounts, a copy of which appeared in our last week's issue, the **Chairman** first referred to the illness of Lord Suffield, who, he was pleased to say, was now much better. The directors thought that the report presented would be considered satisfactory by every shareholder. The public had soon become aware of the advantages of the electric light; that it not only gave the best illuminating power, but was accompanied by no bad air or undue heat, which was not the case with all other illuminants, and the Company's accounts proved that the public believed the Company's system was safe, reliable, and inexpensive The number of lamps installed on January 1, 1895, was 167,703, which had been increased by the end of the year to 210,982, while applications had then been received for 6,478 lights in addition. The increase both in the number of the lamps and of their customers was steadily maintained, although the field they drew upon had decreased. Their capital charges during the past year had increased by about £33,000, or about 8 per cent., but during the same time their revenue had increased by 32 per cent.—from £53,407 in 1894 to £70,511 last year—and their net revenue had increased by £12,410 on the capital expenditure mentioned of £33,000. They regretted to notice that the charge for fire insurance had increased. They had taken every possible means which they knew of to make their buildings practically fireproof, and they had purchased and had on the premises every mechanical appliance known to them for extinguishing fire if one should happen. Moreover, their men were drilled in the use of these appliances. In regard to their revenue the receipt per light was fractionally, but only fractionally, higher than it was in 1894. The increase in their business was not spasmodic, but was all along the line. In regard to depreciation, shareholders generally differed as to how much should be carried to that account. Some had written commending the directors' judgment in placing so large a sum to this account, but a few had expressed the opinion that £9,784 was an excessive amount to put by. The Board had fixed on this figure by following implicitly the advice of their eminent consulting engineer. Prof. Kennedy had divided the respective values of their plant and machinery according to their cost, and had allowed different percentages on each class, with a due regard to how they were likely to wear out. He (the chairman) remarked that his own opinion on such a subject was worth very little, but he might say that he had seen in other undertakings very evil effects arise from not having carried right principles into practice in dealing with depreciation. He had explained at a former meeting that it was necessary to establish a sinking fund to provide for the recoupment of the money paid for their leases, and that they ought to have a reserve fund to provide against any contingency that might happen. Should new discoveries antiquate their machinery or some accident befall it, particularly at a time when the business life of the corporation was coming to an end, and they might be unable to issue new shares advantageously, or to borrow on the security of their undertaking on low terms, a reserve fund invested outside their business, in first-class trustees' securities, would prove very useful to them; and even if no contingency arose, or accident happened, such a reserve fund would be a pleasant bonus for the shareholders at the end of their career. They had therefore invested £3,773 as the nucleus of a reserve fund, and £8,000, the premium on the new shares issued last year, together with the interest which had been already received on these investments. Interest and compound interest invested, and he hoped some additions to the principal, would bring these funds to a very respectable sum in due time. The property which they had lately acquired in Eccleston-place and in Millbank street adjoined their works, and would, when needed, be adapted for them. It was absolutely necessary to be possessed of this land before they stood in immediate need of it, otherwise the owners would raise the price against them.

Mr. Edmund Boulnois, M.P., seconded the motion, which was unanimously adopted, and subsequent resolutions followed authorising a dividend at the rate of 9 per cent. per annum for the half-year, which, with the previous dividend, makes 7 per cent. for the year.

The retiring directors were then re-elected, and, on the motion of **Sir Mark Stuart, M.P.**, seconded by **Mr. Stratton Boulnois**, the Board of Trade auditor was appointed the auditor for the Company.

INDIA RUBBER, GUTTA PERCHA AND TELEGRAPH WORKS COMPANY, LIMITED.

The ordinary general meeting of the shareholders was held at the Cannon-street Hotel on Thursday morning, Mr. S. W. Silver presiding.

The **Chairman**, in moving the adoption of the report, which recommended the payment of a dividend of 15s. per share, congratulated the shareholders on the results of the year's operations. They had passed through a period of many changes not the least affecting their trade, which was greatly improved. The works, having been kept prepared and ready, were in a condition to meet any demands made upon them. The electrical department had been fully employed in erecting installations for important cities, including Brussels, which was considerably extending and increasing its demand upon them. They had manufactured and laid about 300 miles of submarine cable for the Cuban Telegraph Company, and all the other cables turned out had been most satisfactory. The chairman concluded by referring to the death of Mr. Robert Henderson.

Mr. Scott seconded the adoption of the report.

Mr. Wright asked several questions as to items on the balance-sheet, but

The **Chairman** said they could not answer those questions, as they would be giving valuable information to be used against them by their competitors.

Mr. Silver and Mr. Scott were re-elected directors, and the auditors also were elected.

A vote of thanks to the Board concluded the meeting.

MAGDEBURG TRAMWAYS COMPANY, LIMITED.

An extraordinary general meeting of this Company was held on Tuesday, at Birmingham, to sanction the sale of the undertaking of the Company to the Union Elektricitäts-Gesellschaft on the terms of two agreements, dated May 27 and December 13 last. The terms entered into were that the purchase should be subject to the consent of the Town Council of Magdeburg to the transfer of the concessions, the amount of the purchase-money was to be £86,000 cash, to be paid on June 30 next, the tramways to be worked by the Company till that date for their own benefit, and the purchasers were to have the option of completing the purchase at earlier specified dates Inasmuch as the purchase included the Alte Neustadt Depôt, which the Company held on lease, with a purchasing clause at £8,300, it would be necessary for the Company to exercise that option, and therefore that sum must be deducted from the amount which would be available for distribution among the shareholders. The amount of the debenture debt, £25,000, must also be deducted, and assuming that the purchase was not completed before June 26, there would be £52,700 left for distribution, subject to the deduction of the necessary liquidation expenses.

Major Fosbery presided, and in proposing a resolution approving of the sale of the undertaking, said the Company was over-capitalised at the beginning, but the present directors were not responsible for the position of affairs, because they were not associated with the management until some time after the formation of the Company. The result of the sale would be that the shareholders would receive as nearly as possible £5. 10s. for each £10 share, and that was the best bargain the directors could make.

Mr. S. S. Lloyd seconded the resolution, and it was carried.

CITY OF LONDON ELECTRIC LIGHTING COMPANY, LIMITED.

Directors: Sir David L. Salomons, Bart. (chairman), the Earl of Suffolk and Berkshire, Edward Lucas, Colonel B. H. Martindale, C.B., Frederick W. Reynolds. Frank Bailey, engineer to the Company. J. Cecil Bull, manager and secretary.

Abstract of report of the directors to be presented to the shareholders at the ordinary general meeting of the Company to be held at Winchester House, Old Broad street, E.C., on Friday, February 21, 1896, at 2.30 p.m.:

The expenditure on capital account during the year ended December 31, 1895, amounted to £138,456. 2s. 6d. Details of this outlay are given in the capital account. During the year the balance of £100,000 of the present authorised amount of £400,000

Digitized by Google

5 per cent. debenture stock has been issued, and an official quotation for the same has been granted by the committee of the Stock Exchange.

Revenue.

The total revenue for the year was			£109,766 19 10
From which must be deducted the following items:			
Expenses of generation and distribution	£32,324 4 6		
Rents, rates, taxes, general charges, and allowances to consumers	17,004 8 9		
Amount written off suspense account	1,338 0 8		
		50,666 13 11	
Leaving a net revenue of		59,100 5 11	
To which must be added the balance brought forward from 1894		752 13 11	
Making a total available revenue of		59,852 19 10	
Of this sum the following amounts have been distributed:			
(*a*) Interest on debenture stock for year ended December 31, 1895	12,076 16 0		
(*b*) Interim dividend on £400,000 6 per cent. preference shares, half-year to June 30 last	12,000 0 0		
		24,076 16 0	
Leaving for further distribution		£35,776 3 10	

The directors now recommend the following dividends—viz.: 6s. per share on the preference shares for the second half year, making with the interim dividend already paid a total distribution of 12s. per share, or 6 per cent. for the year, and 10s. per share on the ordinary shares for the year, being at the rate of 5 per cent. per annum. This will absorb £32,000, leaving a balance of £3,776. 3s. 10d., which the directors propose to carry forward. The necessary provision for depreciation in accordance with the City of London Electric Lighting Act, 1893, has been made. The generation and distribution expenses for the year, including repairs and renewals, were 36·87 per cent. of the earnings, as compared with 46 for 1894 and 54·2 for 1893. The Company continues to make satisfactory progress, the number of customers and lamps connected at December 31, 1895, being 4,230 and 195,317 respectively. On February 5, 1896, there were 201,128 8-c p. lamps (equivalent) connected, and, in addition, 8,759 awaiting connection. The income as shown in the audited statements of accounts issued by the Company for the year ended December 31, 1895, was as follows: gross revenue, £106 999. 17s. 2d.; net revenue available for interest and dividends, £59,100. 5s. 11d. In September last Mr. Joseph Bevan Braithwaite jun., resigned his seat on the Board. In accordance with the articles of association two of the directors, Lord Suffolk and Mr. Fredk W. Reynolds, now retire, and, being eligible, offer themselves for re-election. Messrs. W. H Pannell and Co. retire, and, being eligible, offer themselves for re-election. The total of the Company on capital account now stands at £1,127,910. 2s. 4d.

HOUSE-TO-HOUSE ELECTRIC LIGHT SUPPLY COMPANY, LIMITED.

Directors: Henry Ramié Beeton (chairman), William Page (managing director), William Reginald Davies, Robert Arthur Germaine, William Francis Leese. Manager: Henry W. Bowden. Secretary: Thos. J. Owens.

Abstract of the report of the directors and accounts for the year ended December 31, 1895:

The revenue account shows a credit balance of £6,840. 16s. 1d., which, with the balance of £108. 11s. 5d. brought forward from the previous year, and £49. 11s. 8d., being dividend on 300 £5 fully-paid ordinary shares in the Yorkshire House-to-House Company, Limited, together with £12. 10s. 5d. for interest on deposit at bank, makes a total of £7,011. 9s. 7d. After deducting £1,907. 18s. 4d. for interest on debenture stock paid and accrued and other interest, and £875 for interim dividend paid on the 7 per cent. cumulative preference shares, the directors recommend that the sum remaining—viz., £4,228. 11s. 3d.—be dealt with as follows: in reduction of preliminary expenses, £500; to credit of depreciation account, £2,000; to payment of the remainder of dividend to December 31, 1895, on the 7 per cent. cumulative preference shares, £875; in reduction of the construction business development account, £788. 11s. 11d.; and that the balance of £64 19s. 4d. be carried forward to the next account—total, £4,228. 11s. 3d. The amount of £829. 9s. 4d. received as premiums on the issue of £10,000 debenture stock it is proposed to apply in further reduction of the construction business development account, thus reducing that item to £15,000. The increase in the lights connected during 1895 was equivalent to 8,304 8-c.p. (35-watt) lamps, being the largest increase since the year 1890, and the increase in revenue was £1,699. 5s. 3d, while the working expenses show an increase of £1,122 4s. 2d. During the year various alterations and additions to the plant have been made, which, it is anticipated, will tend to reduce the cost per unit of electricity in the future; but the effect of carrying out these works, while maintaining continuous running of plant, has naturally tended to increase the works cost for the period under review. A sum of £18,532. 8s. 9d has been expended during the year on additional plant, mains, and buildings and the expenditure for 1896 to meet the increased demand is estimated at £15,000. In order to provide for this outlay a further issue of capital is necessary. With regard to the construction business development account, the directors regret that they have been advised that the accounts of the Leeds and London Electrical Engineering Company, Limited (to whom this business has been leased), do not admit of the distribution of any profit. During the year 1895, a further £10,000 of 4½ per cent. mortgage debenture stock has been issued, bringing up the total issue to £50,000, being the full amount created. Mr. W. R Davies and Mr. R A. Germaine retire from the Board by rotation, and, being eligible, offer themselves for re-election. Messrs. Miall, Wilkins, Randall, and Co., the auditors of the Company, offer themselves for re election.

CHARING CROSS AND STRAND ELECTRICITY SUPPLY CORPORATION, LIMITED.

Directors: G. H. Brougham Glasier, Esq., 7, St. James's-street, S.W. (chairman); Richard Chadwick, Esq., 34, St. Martin's-lane, W.C.; I. P. Mendoza, Esq., 4A, King-street, St. James's, S.W.; Agostino Gatti, Esq., and Stefano Gatti, Esq. (managing directors). General manager and secretary: E. Wilmot Seale, Esq. Chief engineer: W. H. Patchell, A.M.I.C.E., M.I.E.E.

Report of the directors to be presented to the ordinary general meeting of the shareholders to be held at 2, Craig's-court, Charing Cross, W.C., on Monday, February 24, at 12 noon:

The directors, in submitting the accounts for the year ended December 31, 1895, are glad to be able to put before the shareholders a satisfactory report of the working of the Company. There has been a constant increase in the demand for current, while on December 31, 1894, the Company were supplying energy to 41,216 8 c.p. lamps, they were on December 31, 1895, supplying to 51,302 8-c.p. lamps, being an increase of nearly 25 per cent. ever those supplied in that year, and 48½ per cent. over those supplied in the year 1893. The station has been maintained in a high state of efficiency, but the directors have thought it well to carry £3,000 to depreciation account. The provisional order enabling the Corporation to supply electricity in the district of the Strand District Board of Works was granted by the Board of Trade, and the Bill confirming it passed a Committee of the House of Lords; owing, however, to the dissolution of Parliament, the Bill

Digitized by Google

could not be dealt with by the House of Commons, by whom it will be considered in the present session of Parliament. In view of the large increase in the business of the Corporation, a wharf and spacious premises, covering an area of 29,000 square feet, have been secured in the Commercial-road, Lambeth. The necessary alterations to render the premises suitable for an electric lighting station are now being made, and trunk mains laid connecting up the proposed station with the existing station of the Corporation at Maiden-lane. The net earnings, as shown in the revenue account, have amounted to £12,587. 3s. 11d.; £700 has been written off for preliminary expenses; £300 from law costs suspense account; £3,262. 10s. has been paid in respect of interest on debentures up to December 31, 1895; and £2,899. 18s 10d. was distributed in payment of an interim dividend at the rate of 4 per cent. for the half-year ended June 30, 1895. A sum of £5,424 15s. 1d. now remains, which, added to the undivided profit of £304. 19s. 10d. from last year's account, makes £5,729 14s. 11d, and which the directors propose to deal with as follows: to pay a dividend (less tax) at the rate of £6 per cent for the half-year ended December 31, 1895, making with the interim dividend paid in August, 1895 £5 per cent. per annum for the whole year, £4,350. 1s 2d.; and to carry forward, £1,379. 13s. 9d. Mr. Stefano Gatti and Mr. Richard Chadwick are the directors who retire by rotation and, being eligible, offer themselves for re election. The auditors, Messrs. O. R. Johnson and Son, also retire and offer themselves for re-election.

NATIONAL TELEPHONE COMPANY, LIMITED.

The report of this Company for the last six months of 1895 states that the income amounted to £422,649, as compared with £378,789 for the corresponding period of 1894 an increase of £43,860. The working expenses were £216,537, as compared with £205,192, an increase of £11 344. The net result, after deducting the Post Office royalties, amounting to £38,238, is a profit balance of £167,874, as compared with £138,643, an increase of £29,231. The rentals carried forward for unexpired terms of running contracts amount to £354,635, as compared with £313 979, or an increase of £40 656. Out of the available balance of £138,217 the Board recommend the payment of a dividend at the rate of 6 per cent. per annum less income tax, on the first and second preference shares, 5 per cent. per annum, less tax, on the third preference shares and 6 per cent. per annum, free of tax, on the ordinary shares. The Board also propose to transfer £35,000 to the reserve fund, and to carry forward the balance of £6,623. With regard to the preliminary agreement for the acquisition by the Post Office of the Company's trunk lines, it is stated that the many difficult questions involved in the settlement have led to some further delay. Happily, however, the amount due to the Company is now practically agreed, and there is reason to believe it will very soon be paid. In the meantime the Board is loyally co-operating with the Post Office in preparing for that transition in the conduct of the trunk business of the country which will follow the assumption of the trunk lines by the State.

NOTTING HILL ELECTRIC LIGHTING COMPANY, LIMITED.

Directors: William Crookes, Esq., F.R.S. (chairman); Arthur Ellis Franklin, Esq.; Alexander Howden, Esq.; James Thomas Jervis, Esq; Francis Radford, Esq.; Sidney Waters, Esq. Engineer and manager: G. Schultz. Secretary: R. G Rawkins.

Report of the directors and abstract of accounts to be submitted to the shareholders at the ninth ordinary general meeting to be held at the offices of the Company at Bulmer-place, Notting Hill, on Tuesday, February 25, at 5.30 p.m.:

The expenditure on capital account at the date of the last balance-sheet stood at £78 335 16s. 1d. During the past year a further sum of £5,702. 18s. has been expended. The largest item is for an additional battery of accumulators, which has been rendered necessary by the expanding business of the Company, and the balance is principally for mains in Addison-road and for other extensions. The required capital has been raised by the issue of ordinary preference shares, and owing to an increased demand for these shares, the directors have been able to obtain a premium of £2 a share in recent allotments. The amount of premiums thus obtained—viz, £246—has been applied to the reduction of the preliminary expenses account. The whole of the remaining unissued shares, amounting to £11,380, have been applied for at the same premium, and when allotted the directors will be enable to apply the premiums realised (£2,276) to the further reduction of this account. The revenue account shows a profit of £3 227. 14s. 10d., as compared with profits of £2,101. 17s. 8d. in 1894; £1,481. 7s. 1d. in 1893; £112. 6s. 1d. in 1892; and a loss of £554. 18s 6d. in 1891. The number of lamps on the circuit has increased from 15,669 to 20,307, being an increase of 4,688 lights, against increases of 3,516 in 1894, 2,715 in 1893, and 3,382 in 1892. The amount received from the sale of current shows an increase of £1,686. 12s. 2d., following an increase of £687. 4s. last year, and has now reached a total of £5,881. 0s. 10d. The expenditure on repairs and maintenance has been £780. 3s. 3d.,

Digitized by Google

an increase of about £270 over last year. This increase arises from special additions which might have been charged against the depreciation reserve: the whole of this amount was, nevertheless, paid out of revenue. The sum of £700 has been set aside for depreciation and renewals, making up this fund to £1 300, and after writing 3 per cent. off the preliminary expenses and allowing for the other items on the net revenue account, a balance remains of £2 329. 9s. The directors recommend the following dividends: (1) 6 per cent. less income tax on the ordinary preference shares for the year ending December 31, 1895, £901. 17s. 2d.; (2) 2 per cent. free of income tax on the ordinary shares, £1,290. 8s.; carrying forward the balance of £137. 3s. 10d. In their last report the directors explained the position of their application to Parliament for powers of supply over the northern part of Kensington. The provisional order from the Board of Trade was duly obtained, and the confirming Bill brought into Parliament, but unfortunately it had not passed through its final stages at the time of the recent dissolution, and it will therefore be proceeded with again during the present session, no opposition being anticipated. The engineer and manager, whose valuable services have before been referred to by the directors, reports that the machinery, plant, and mains are in good condition, and no accident of any kind has occurred The directors who retire are Messrs. William Crookes and Sidney Waters, and, being eligible, they offer themselves for re-election. The shareholders' auditors, Messrs. Fox, Sissons, and Co., retire, and, being eligible, they offer themselves for re election.

CONTRACTS FOR ELECTRICAL SUPPLIES.

CONTRACTS OPEN.

Parma (Italy).—The municipal authorities of the city of Parma desire tenders by February 25 for the electric lighting of the city from June, 1897, to 1912.

Namur.—Tenders will be received on July 10 next for the construction of a telephone building at Namur. Plans and particulars can be obtained from le Service Téléphonique, Namur.

Leeds.—Firms desiring to tender for the various works required in extension of the electric light station in Leeds, should send their names to Messrs. Milnes and France, architects, 99, Swan-arcade, Bradford.

Teneriffe (Canary Islands).—Tenders are invited for the electric lighting of the town of Santa Cruz, Teneriffe, for a period of 35 years. Particulars can be obtained at the Ministerio de la Gobernacion, Madrid, and tenders must be delivered by February 29.

Elberfeld.—Tenders will be received on February 28 for the supply to the Prussian State Railways of iron wire, bronze gutta-percha-covered wire, insulators and supports, etc., for the telegraphic service. Address, Die Konigliche Eisenbahn-Direktion, Elberfeld.

Bangor.—Tenders are invited by the Corporation for the construction, supply, and laying down of the necessary plant and mains for the supply of electricity in the borough. Tenders are to be sent to the town clerk by March 18. Full particulars will be found in our advertising columns.

Brunn (Austria).—The Municipality desire offers for the construction and working of a central station for the supply of electric energy for lighting the town, for power, and, if required, for running a tramway. Tenders must be sent before March 31 to the Bürgermeister, Brünn, Austria, from whom particulars can be obtained.

Lisbon.—Tenders are wanted by the Royal Portuguese Railway Company for the supply of apparatus for electric alarm bells. Tenders, suitably endorsed, must be sent to the Chief Engineer, at the Company's Stores, Santa Apolonia, Lisbon, by March 11, and particulars, etc., can be obtained from the Paris Offices of the Company, at 28, Rue de Châteaudun.

Sunderland.—The Town Council ask for tenders for two continuous current dynamos and engines, three Babcock and Wilcox boilers, an economiser, and water-softening plant. Particulars can be obtained from the borough electrical engineer at the electrical supply station, Sunderland, upon depositing £1. 1s, and tenders must be in by March 13.

Eston.—The Eston Urban District Council invite schemes for lighting the district by electricity. Such schemes to embrace (*a*) plan and estimated cost, (*b*) annual working cost and maintenance. Plan of the district may be seen and particulars obtained of Mr. T. W. Stainthorpe, A.M.I.C.E., district surveyor, Grange-town, Yorkshire, to whom the plans, etc., must be sent by May 1.

Hanover.—Tenders are wanted for the supply of anthracite coal to the amount of 2,250,000 kilogrammes (about 230,000 tons) during the year for the municipal electric supply station. Tenders for lots of 10,000 kilogrammes are to be sent in by February 29, and particulars can be obtained for 50pfg. (6d) from the Registratur, Stadtisches Elektricitätswerke, Hannover.

Keighley.—Tenders are invited for providing and fixing telephonic communication between the various buildings forming the infectious hospital now in course of erection at Morton Banks, near Keighley, for the Keighley and Bingley Joint Hospital Board. The buildings and plans can be inspected on application to Mr. Alfred Moore, clerk of the works at the hospital. Tenders, marked on the outside "Tender for Hospital Telephones," will be received by Mr. Geo. E. Spencer, clerk, North-street, Keighley, not later than noon on March 4.

Hanover.—Tenders are wanted for the supply to the State Railways during the ensuing year of certain articles for the telegraphic service of the districts of Altona, Cassel, Erfurt, Hanover, and Münster. The contract includes 250 lamp globes, 40,000 lamp chimneys 38,600 zincs and 22 500 coppers for galvanic batteries, 40,900 kilogrammes sulphate of copper, 5,040 kilogrammes sulphate of zinc, 159,700 rolls of paper-tape, etc. Conditions and particulars can be obtained from the Rechnungsbureau, Königliche Eisenbahn Direktion, Joachimstrasse, Hannover.

Cologne.—Tenders are invited for the supply of about 8,300 battery cells, 9,900 stoppers and glass funnels, 19,200 zincs, 11,720 coppers, a quantity of connections, 38,640 kilogrammes of sulphate of copper, 5,400 kilogrammes of sulphate of zinc, 8,100 bottles of ink, 316,500 rolls of paper-tape for the telegraphic service of the State Railways at Cologne, Elberfeld, Essen, Frankfort-on-the-Main, and St. Johann-Saarbrücken (44 lots).

Digitized by Google

Particulars and conditions can be obtained for 80pfg. (10d.) from the Königliche Eisenbahn Direktion, Centralbureau, Domhof Nr. 28, Köln a. Rh., and tenders must be in by February 29

Chesterton (Cambs).—The Urban District Council is open to receive tenders for the public lighting of the district for seven years. The tenders shall be made in the three following modes—namely, (*a*) lighting the district from August 14 to May 15 (inclusive) in each year; (*b*) lighting the district throughout the whole year commencing May 15 next; (*c*) lighting the district for either of the above periods (1) with ordinary burners, (2) with incandescent burners, if the illuminant with which the tender be made be gas. All cleaning, lighting, and maintenance to be done by the contractors. Tenders to be sent to Mr. James Spearing, clerk, 15, Sydney-street, Cambridge, by 28th inst.

Islington (London).—The Vestry of St. Mary, Islington, invite tenders for electrical engineers' stores, etc. Forms of tender and further particulars may be obtained, and the draft contract inspected by application, between 10 a.m. and 12 noon, at the Vestry Hall, Upper-street, N. No tender will be received after 12 noon on 27th inst. Persons tendering must be prepared with a £10 note, to be deposited (not enclosed with the tender), as a guarantee of good faith until the execution of the contract. Those tendering for more than one of the items must enclose each tender in a separate cover, and be prepared to deposit a separate £10 note with each tender. Each cover must be properly endorsed.

Tunbridge Wells.—Tenders are wanted for the enlargement of the central electric lighting station, adjoining the South-Eastern Railway goods station, at Tunbridge Wells, for the Corporation, to be carried out under the superintendence and in accordance with drawings prepared by the borough surveyor, Mr. T. E. W. Mellor, A.M.I.C.E. The drawings and specification may be inspected at the office of the borough surveyor, town hall. Persons wishing to tender may obtain bills of quantities on application to Mr. W. C. Cripps, town clerk, Town Hall, Tunbridge Wells, accompanied by a fee of £2. 2s., which fee will be returned on receipt of a bona fide tender. The person or firm whose tender is accepted will be required to enter into a formal contract and a bond with two approved sureties for the performance of contract. Sealed tenders, endorsed "Electric Light Station," must be sent to the town clerk by 25th inst.

RESULTS OF TENDERS.

Liverpool.—The tender of Messrs. Craven Bros, Manchester, £65, has been accepted for erecting an overhead travelling crane in the engine-house at Aubrey-street, for the City Council.

Taunton.—The Electric Lighting Committee have received tenders for the supply of 1,000 tons of steam coal, and accepted that of Messrs W. Thomas and Co. for Powell Duffryn best large steam at 14s. 4d. per ton, delivered at the works, a weight note to be delivered with each load at an extra cost of 2d. per ton.

Harrogate.—The following tenders have been accepted for the works required in the erection of electricity generating station on the Corporation farm, near Harrogate, for the Corporation. Mr. Samuel Stead, borough surveyor:

J. Stephenson, Florence House, Oatlands Mount, Harrogate, mason, etc.	£2,747	18	0
G. A. Carrick, Little Wonder, Harrogate, joiner, etc.	240	0	0
G. A. Terry, 3, Holderness-terrace, King's-road, Leeds, painter	26	17	9
T. Rayner, 35, Franklin-road, Harrogate, slater	83	5	3

Swadlincote.—The following were the tenders received for lighting the township of Stanton with electric light, for the Swadlincote Urban District Council. Mr. R. Cartwright, Swadlincote, surveyor:

Hall and Geary, Church Gresley, near Burton-on-Trent (accepted)	£120	0	0
Fletcher, Hirst, and Co., Burnley	117	0	0
Cutting Bro., Derby	119	0	0
Electric Construction Company, Limited, Wolverhampton	145	0	0
Walsall Electrical Company, Limited, Walsall	151	0	0
Ellis and Ward, Birmingham	179	0	0
H. M. Edwards, Cardigan Works, Wakefield	186	10	0

BUSINESS NOTES.

Ross.—There are at present about 400 navvies employed at the aluminium works at Foyers.

Liverpool.—At the new Dingle Station of the Overhead Electric Railway a shed is to be erected for the stabling of bicycles.

Southend.—Messrs. Crompton and Co., of Chelmsford, estimate the cost of the additional plant for lighting the town by electricity at £2,900.

Portobello (Midlothian).—The Town Council have appointed a committee to consider and report as to introducing the electric light into the burgh.

Neston.—The electric light is being installed at Ashfield Hall by Mr. J. S. Harmood Banner. The installation will be of a very elaborate character.

Portsmouth.—The Town Council have decided to light Goldsmith avenue with 28 electric lights (incandescent), and run mains through, at a cost of £1,500.

Peterborough.—The Town Council have decided to apply to the Local Government Board for sanction to borrow £20,000 for the electric lighting of the city.

Radcliffe (Lancs.).—The Urban Council have resolved that the compulsory area for electric lighting purposes be a limit of 200 yards from the main trunk line.

Southport.—The telephone has proved of great service throughout the Corporation departments, but intercommunication is needed between the Southport and the Birkdale police systems.

Bury St Edmunds.—In view of the Corporation's proposal for an electric lighting scheme, the gas company at their general meeting considered the question of introducing improved incandescent gas lamps.

Brush Company, Limited.—Notice has been given that the first debenture stock transfer books of the Brush Electrical Engineering Company, Limited, will be closed from February 19 to March 3, 1896, both inclusive.

The Furness Railway.—The directors have decided to light experimentally two of the main-line passenger trains with Stone's system of electric lighting, in place of the unsatisfactory system of lighting by oil lamps.

Liverpool Overhead Railway.—The traffic receipts of this railway for the week ending February 16 amounted to £1,134, as compared with £843 in the corresponding week of the previous year, being an increase of £291.

Harrogate.—The borough surveyor has laid before the General Purposes Committee draft specifications which he had prepared for the works in connection with the electric light buildings, and after revision they were approved.

Leeds.—The Tramways Committee of the Corporation were to have visited Bristol on Monday to inspect the electric tramway, but the visit had to be deferred to meet the convenience of those who were to receive the deputation.

Newcastle-on-Tyne.—The poll of the ratepayers upon the tramways question, which was demanded at the town's meeting on January 15 last, commenced on Saturday and closed on Wednesday. The counting begins to-day (Friday).

Leeds.—At the Municipal Offices Messrs. Hopper and Sons offered for sale by auction electric lighting plant, engines, and boilers, put in by the Leeds Corporation about six years ago at a cost of £5,000 The amount realised was £1,684. 2s. 6d.

South Africa.—Messrs. Meldrum Bros., of Manchester, have received instructions to equip the new electric supply works of Johannesburg with their patent forced-draught furnaces, and the Durban electric supply works are to be similarly equipped.

Cardiff.—Mr. Hallett has reported as to the allegations made in connection with the electrical department. He suggested several alterations in the staff, and said there was nothing serious the matter with the machinery. The Corporation have adopted the report.

Telegraphic Material.—The Customs House returns show that during January last the value of the exports of telegraphic wires and apparatus connected therewith was £57,224. For the same month in 1895 and 1894 the amounts were respectively £35,193 and £18,738.

Northampton.—The electric light company report that, after allowing £250 for depreciation, there is sufficient, and a small balance over, to pay 1½ years' interest up to last June on preference shares. A dividend to ordinary shareholders thus is thought to be within measurable distance.

Coatbridge.—At a meeting of the Town Council, Councillor O'Neil gave notice of motion for the appointment of a committee to consider the advisableness of the Town Council acquiring the works of the gas company and the electric lighting company, with a view to working these in the public interest.

Obituary.—We hear with regret of the death of Mr. John A. Bird, the managing director of Rose and Bird, Limited, which took place after a very brief illness on Thursday, 13th inst. We are informed that arrangements have been made so that the business of the company shall be carried on as usual.

Aberdeen.—After the successful experiment with the lighting of their carriages by electricity, the Great North of Scotland Company have now permanently introduced the system in their suburban trains between Aberdeen and Dyce. The new illuminant is regarded as a great improvement on the old method.

Hampstead (London).—The Lighting Committee have reported to the Vestry that they had instructed the vestry clerk to prepare a full report on the electric lighting undertaking to the end of the year 1895. A fund has been opened on behalf of the parents of Edwin Clarkson, the victim of the recent fatal accident.

City and South London Railway.—The returns for the week ended February 16 were £949, compared with £998 for the corresponding period of last year, being a decrease of £49. The total receipts for the half-year terminating as above were £6,946, compared with £7,039 in the same period of the preceding year, being a decrease of £93.

Tramways Union.—The report of this company, to be presented at the annual general meeting on the 25th inst., refers to the circular on electrical traction addressed to the shareholders last July, and adds that the directors are glad to be in a position to report that considerable progress has been made towards obtaining the necessary powers therein alluded to.

Coventry.—Last week some excitement was caused at Coventry by a breakdown in connection with the electric tramways. A car had passed a junction of the overhead wires about two-thirds of the way down Hertford-street, when some sparks were seen flashing from the trolley wire, which shortly afterwards fell. The car stopped suddenly. The wire for some length fell to the ground.

Digitized by Google

Buralem.—At a meeting of the Wolstanton Rural District Council to consider the proposal of the North Staffordshire Tramway Company to extend their lines into the district of the Council, it was unanimously decided to agree to the proposed extensions from Longport to Wolstanton and from Sandyford to Golden-hill, subject to a time limit being fixed by the Board of Trade.

Metropolitan Asylums Board.—It has been determined to invite tenders for the provision of telephonic communication and electric bells and fire alarms at the Brook Hospital, and the Fountain Hospital Committee reported the acceptance of an estimate, at the sum of £59. 7s. 4d, from the Private Wire and Telephone Installation Company, to make good the defects in the electric bell system.

Huddersfield—At a meeting of the Tramways Committee it was stated that no further communication had been received from the London and Provincial Electric Traction Company, Limited, who made overtures to the Corporation for a lease of the tramways. The Local Government Board have granted the Corporation authority to borrow £50,000 for electric lighting. The Town Council have agreed to the extension of the tramways.

Belfast.—A deputation of the Town Council has visited Dublin and Bristol to examine into the question of electric tramways. Havre, Paris, Brussels, and Berlin are also to be visited by the deputation. Mr. A. Hamilton Smythe, C.E., appointed by the Board of Public Works in Ireland, has held an enquiry concerning the proposed street tramways. Mr. Nance (assistant borough surveyor) stated that the total length of the proposed double lines was 6 miles 7 furlong 8·6 chains.

Lochee (Forfarshire).—The electric light, which has been fitted throughout the baths and library, is generated by a dynamo which has been placed over the drying-chamber in the laundry, and which is capable of working up to 50 amperes. The power is obtained from the engine which drives the laundry machinery. A main switchboard has been fitted convenient for the attendant, and from this control of the whole installation is had. Messrs. James Maxwell and Son have carried out the work. This is the first public installation of the electric light in Lochee.

Prestwich—At the meeting of the Urban District Council a report was presented on the electric lighting of the district, which set forth that by an outlay of about £5 000 a reasonable profit would be made provided not less than 6,000 lights were used; but it would not be wise for the Council to proceed further in the matter until it had been ascertained whether it was likely that this number of lights would be used. With a view to obtaining this information it was recommended that circulars be issued to the residents and ratepayers. The report was adopted.

Dublin.—The Corporation have had under consideration two proposals for introducing the principles of electric traction into the street-car traffic of the city. The South District Tramway Company, which has an electric line on the outskirts of the city from Balls Bridge to Kingstown, but no footing inside the city, proposed an extensive scheme, and of this, on the advice of the city engineer, 13 miles were approved at a rental of £4,000 per annum, the rental to be revised every five years. By 21 votes to 17 the overhead trolley system of electric traction was approved.

Ayr.—A report by the electrical engineer, submitted at the meeting of the Council, recommended that additional plant be got. Mr. R. M. Beveridge held that the Council were being made toys of in connection with the electric light. He held that there had been bungling, and that the time had come when they were not going to sit by with their fingers in their mouth. This electric light held the Town Council up to contempt to the inhabitants and visitors to the town. Mr. Park, the electrical engineer, thought the light for dwellings would be ready in the first week of March.

Morecambe.—At a meeting of the District Council Mr W. R. Brown produced a catalogue of articles to be sold at the electric works, and asked whether it would be advisable to appoint someone to purchase articles which would be of use to the Council Mr. J. Brown replied that the engineer appointed by the Council had valued everything that would be useful to them, and the things to be offered for sale would be of no use to the Council. The seal of the Board was affixed to the agreement between the Council and the electric light company on the motion of Messrs. J. Brown and W. Harper.

Hull.—At a meeting of the Electric Lighting Committee Mr. Skinner, deputy chairman, moved, "That this committee regrets the retirement of the late chairman from the committee, and they take this opportunity of expressing their appreciation of the services rendered by him to the town in the establishment of the now successful electric lighting station." Mr. Atkinson seconded the motion which was carried unanimously. Mr. Atkinson moved, and Dr. Kessen seconded, that Mr. Skinner be appointed chairman of the committee. The motion was carried unanimously. Mr. Millington was elected deputy chairman.

Torquay.—According to the latest modifications of the electric lighting scheme, it is stated that it is proposed to utilise cellars adjoining the Bath Saloons as a generating station The whole of the sea-front from the Bath Saloons to near the railway station is to be lighted by electricity. Fleet street is also to be lighted, and Union-street, from the Strand to Tor Station. The 70 arc lamps necessary for this are estimated to cost £1,260. For private lighting, mains are to be laid in the following roads: Happaway-hill, Warberry-road, Torwood-street, Meadfoot-road, Babbacombe-road, Higher Erith-road, and Lower Lincombe-road.

Catalogue.—We have received a catalogue and price-list (Section A) from Messrs. P. R. Jackson and Co., Limited, steel and iron founders, millwrights and electrical engineers, of Manchester. Numerous photographs are published of the works at Salford Rolling Mills, and also of the machinery, patterns, castings, etc., and a useful and complete price-list is appended. This firm has been very successful in its new electrical department, and, in addition to a large number of dynamos for electric lighting and the transmission of power in mines and mills, there are on order eight large dynamos of 270 kilowatts each.

The Isle of Man Tramways.—The Isle of Man Electric Tramway Company have issued a notice to the shareholders stating that the Company intended to apply for sanction at an extraordinary general meeting to purchase the Snaefell Mountain Railway for £72,500, the purchase-money to be payable £32,500 in cash, £20,000 fully-paid 6 per cent. preference shares, and £20,000 ordinary shares. The Company is asked to increase the capital to £175,000 by the creation of 25 000 new £1 preference shares. The Company's system will then extend 12 miles from Victoria Pier to the summit of the Manx Monarch Mountain.

Bradford.—The sub committee of the Gas and Electricity Committee have met to consider matters relating to the new electricity works They decided to entrust to Messrs. John Brown and Co., Limited, of Sheffield, the construction of the new boilers, fans, and some other machinery for the new works. It being reported to the committee that the Board of Trade had sanctioned the increased voltage recently referred to, the committee gave instructions for the preparation of estimates of the cost of the extension of the supply of light along Manningham-lane as far as Queen's-road, with the view of proceeding with such an extension if the applications are numerous enough to justify the expenditure.

Willenhall.—At a meeting of the Urban Council, the General Purposes Committee reported that they had considered the application and position of the fire brigade, and they recommended that no more than £70 be spent in providing electric calls from such station to the residences of the firemen. Councillor Tayler moved that the recommendations be adopted, and Councillor Knowles seconded. Councillor Parkes said he could not vote for the amount for electric calls. He was in sympathy with the brigade, but possibly during the next six or twelve months they might have to remove their stores to a more suitable place. The report was adopted, no member voting against it.

Warminster.—At the Urban Council meeting the Clerk said he had received a letter from Mr. Toone offering to supply the necessary electric current for lighting the arc lamp on the fountain He had made a calculation that the lamp would be lighted 1,640 hours, and the previous contract was ridiculously low, and Mr. Hill must have been considerably out of pocket by the transaction. On the Council laying down the cable, maintaining the lamp, and renewing the carbons, he would light the lamp from sunset to 11.15 p.m. and from 6 a.m. to sunrise each day, except Sundays, for £24 per annum. The matter was referred to the Sewage and Electric Light Committee for consideration and report.

Darjiling (India).—Mr. Mitchell, of the firm of Messrs. F. Osler and Co., Calcutta, has visited the Rungli Khola and Little Rungneet Rivers with the purpose of discovering a means of water power to work turbines for electric lights for the town. He observed that the water-flow at Rungli Khola was not sufficient to work a turbine capable of lighting the town with electricity, but that the Little Rungneet would be better suited to fulfil the work. The spot selected is near Sidrapong. It is proposed to start the generating power there and to conduct the current to the town, a distance of about three miles.

Halifax.—There was a large attendance of members of the Town Council on the occasion of their visit last week to the electricity works, Foundry-street, to witness the starting of No. 4 engine, which has been supplied by Messrs. Pollit and Wigzell, Sowerby Bridge, at a cost of about £3,000. It is a vertical compound-condensing engine, with a speed of 140 revolutions per minute and a stroke of 2ft. 6in. The engine is 600 h.p., and is fitted with Corliss valves. It is directly coupled to a 300 kilowatt alternator, the machine being built round the flywheel. The Mayor started the engine, and afterwards, at the invitation of Alderman Woodhead, the company adjourned to the offices, where refreshments were served.

J. D. F. Andrews and Co.—We are informed that Mr. J. D. F. Andrews has severed his connection with the firm hitherto carried on, under the name of J. D. F. Andrews and Co., at 34 Victoria-street, and has started in business on his own account under the same name (J. D. F. Andrews and Co) by Putney Bridge Station, London, S.W. Mr. J. D. F. Andrews has made some improvements in his system of concentric wiring. These relate more especially to a new wire which he has devised for the system, for the manufacture of which he is setting up plant at Putney Bridge Station. The new wire is neat in appearance, and is sufficiently stiff to be fixed to a wall in perfectly straight lines. The outer conductor is a copper tube, and the insulation is fire resisting.

Worcester.—The Street-Lighting Arc Lamp Sub-Committee have recommended an extension of the arc lamp lighting by the provision of further lamps in College-street, Sidbury, Bridge-street, the Bridge, St. Nicholas-street, and Lowesmoor. This would entail capital outlay of £1,850 for laying down mains, etc., and the lighting would cost £650. or for less than three times the cost of the gas-lamps, the Council would have 20 times as much light. At £650 per annum 26 lamps would displace 74 gas-lamps, of which 55 were double burners, lighted at a cost of £222 per annum. This extension would require four new circuits, and the

Digitized by Google

mains would be of sufficient sectional area to allow of future extensions. The gas-lamps to be displaced had an aggregate candle-power of about 1 600.

London Extensions.—Notice under Electric Lighting Acts and Orders having been given by the County of London and Brush Provincial Electric Lighting Company of intention to construct two large transformer boxes, the one at Field-place, St. John-street-road, and the other at Peartree-court, the committee of the London County Council recommended this should be sanctioned subject to the condition that there shall be no gas-pipe within such distance from any box as is equal in feet to the diameter of the gas-pipes in inches, and that adequate means be taken to prevent the accumulation of gas in the boxes and conduits. Notices were also passed from the Vestry of St. Pancras of intention to lay mains across Camden-road; in Gray's-inn-road, Wells street, and Phœnix-place; and to lay a lead-covered cable in stoneware casing in Judd-street.

Edinburgh.—The members of the Edinburgh Architectural Association were conducted over the electric lighting station at Torphichen-street last week under the guidance of Mr. Monkhouse, the resident engineer. On assembling in the engine-room Mr Monkhouse made a short statement regarding the machinery, its capacity, and the intentions of the Electric Lighting Committee regarding an extension of power. In reference to the expenses incurred in opposing a claim made by the company possessing the electric lighting patent of Dr. Hopkinson, which would expire in July next, for a renewal of the patent, it was stated in the Town Council that, should the company be successful in this point and in proving that Edinburgh had adopted the patent, the Corporation might be mulcted in an annual rental of £700, increasing on extensions, for 14 years.

Fareham.—The District Council have obtained the consent of the Local Government Board to the raising of a loan of £6,681 for the purchase of the electric light undertaking, the laying of electric lines underground, the purchase of lamp columns and an additional engine, and the cost of an additional adviser. The central body has, however, refused to sanction the borrowing of £200 for the purchase of additional land, and of £120 for larger wire for the underground lines; but it is thought that sanction will not be withheld in these respects when a little further explanation is given. The District Council have resolved upon coming to a speedy settlement forthwith, subject to the approval of the Board of Trade, and have decided to engage an electrical engineer to advise them in the matter. Mr. E. Manville, if willing to act, is to be invited to state his terms.

Taunton.—The Town Council have decided to increase the salary of the borough electrical engineer (Mr. Couzens) by £50 per annum. The electrical engineer reported as follows: "We have laid the main to Staplegrove for the supply of Pinkhurst, and we are now commencing to test the same. The cables and plant for No. 3 transforming sub-centre are in hand, and will be laid shortly. As regards the other mains, I have gone into the matter very carefully with Dr. Fleming, and these will be laid of adequate capacity, and in such a way as to meet the probable future requirements of the district which they serve. Since writing my last report we have fixed the new engine and alternator, and are running the plant regularly. Dr. Fleming made an inspection of this extension and the works generally on December 4 last, and reported to the committee thereon."

Bristol.—After discussion the Electric Lighting Committee have decided to recommend to the Town Council that no objection should be raised to the tramways company using electric traction on the tramway to Fishponds-road and supplying the current from their present station at St. George, on condition that any future proposal for the adoption of electric traction in other parts of the city must be on the principle of the current being supplied by the Corporation. The committee express the opinion that, having regard to the large outlay of capital undertaken by the Corporation to enable them to supply electricity for all purposes and to the fact that they are prepared to undertake such supply, all future applications for extension of electric traction within the city should only be entertained upon the condition that the electricity be supplied by the Corporation.

Bath.—The City Council have again had before them the question of the electric lighting of the city and the respective applications of the Council and the electric lighting company to the Board of Trade for a provisional order. The company are anxious to obtain a provisional order for 40 years and to extend the lighting area, but the Council want to have the electric lighting of the city under their own control and are applying for the provisional order themselves The committee in their report asked that they might be allowed to proceed upon the basis of the advice of Mr. Hammond, their consulting engineer, who, in an exhaustive report to the Council, recently specified what portion of the company's plant might be acquired in the public interests The report was adopted without discussion, as it was thought unwise to go into the details of the negotiations in public.

Harwich.—At the Town Council's quarterly meeting the Public Health Committee reported that they had exhaustively considered the tender of the Towns and Villages Electric Lighting Company for the supply of an installation of electricity for public and private lighting, but the company having withdrawn their offer to purchase the rights of the Corporation under the Harwich (Corporation) Electric Lighting Order, 1892, they recommended that the negotiations be terminated. The Mayor said the company gave them to understand from their tender that they were going to supply the plant, etc, but had declined now to do so. The initial outlay for such plant, etc., would mean a great expense to the borough, and he (the mayor) thought the Council were justified in retracting from what the Council did on November 9. Several members concurred, and the recommendation of the committee was unanimously adopted.

Yarmouth.—At the meeting of the Town Council the surveyor reported that since the last meeting applications had been received from five new customers for 155 lamps making the total number of customers 145 for 6,647 lamps In addition to the applications named above, there was one on the North-quay requiring a considerable extension of the mains. The income for the past month was £284. 6s. 8d.; the expenditure amounted to £149. 19s. 7d.; earned beyond cost of production, £134. 7s. 1d. The repayment of capital, interest, rates, and insurances now amounted to about £100 per month. The surveyor was instructed to ascertain whether there are likely to be any additional customers upon the North quay. Messrs. Turrell and Torkildsen made application for and obtained leave to lay the electric light into the office at 23, South quay, which they hire of the Corporation.

London County Council.—On Tuesday the Parliamentary Committee reported as follows: "By the United Tramways Provisional Order it is sought to exempt the company from the provisions of the London Overhead Wires Act, 1891, and the by-laws made under the Act, and to authorise the company, with the consent of the Council to place overhead wires for working the tramways by electrical or other mechanical power, including the overhead trolley system of electric traction or any other system. The Council twice last year refused its consent to the use by this company of electric traction by means of overhead wires, and, having been informed by the Highways Committee that in their opinion the granting of the order should be opposed, we recommend that the Council do refuse its consent to a provisional order being granted to the London United Tramways Company." This was agreed to.

Dewsbury.—Speaking on the motion for the adoption of the Lighting Committee's report at the Town Council, the Mayor said that, so far as the electric light of the town was concerned, they seemed at present to be in a fair way of securing some return for the outlay made. For instance, he found that last week there was a result of £40 to the good. He did not mean to say that there would be such a return for every week in the year. More electricity was being required; and since the beginning of November there had been a gradual increase in the consumption. Councillor Wilby said he had been informed by a member of the Council that, in the storing of electricity, there was a loss of something like 47 per cent. Was there any truth in that? The Mayor said there was a loss, and they would remember that the committee had ordered a new engine and dynamo, and as soon as they had obtained it they would be able to do away with the loss.

Llandrindod Wells.—It having transpired since the last meeting of the Urban District Council that Mr. Edward Davies, J.P., of Llandinam, was prepared to form a company to provide an installation of the electric light, and would undertake to light the public lamps (32 c.p) at 40s. per annum, against 58s. 6d. under the hitherto proposed contract, and private lights at 6d. per unit, against 7d. and 8d. under the contract, after a heated debate, it was resolved to inform the contractors with whom negotiations had been going on (Messrs. Jevons and Thomas) that the Council were not now prepared to proceed with the proposed contract Although the standing orders prevented any definite decision being arrived at as to the alternative scheme, it was agreed that Mr. Edward Davies's order should be accepted at the next meeting, and Mr. Davies subsequently attended the meeting and arranged for the immediate completion of the business, so that the street-lighting may be installed by next August.

Wakefield.—At the City Council meeting Councillor Cradock was added as a member of the Electric Lighting Committee. Councillor Moorhouse remarked that he hoped now that the committee was complete no time would be lost in calling it together. He believed it had only been once called together since the 9th of November, and in the present position of affairs he thought this was an unfortunate delay. Alderman Sherwood, chairman of the committee, said, in answer to Councillor Moorhouse, that there was very little to meet about at the present moment, for the simple reason that they were waiting for the order of the Local Government Board sanctioning the borrowing of the money. Councillor Moorhouse said it was not information, but customers that they wanted now. The new County Council offices are to be supplied with the electric light from the Corporation's works about to be constructed at Calder Vale, upon which the sum of £25,000 has to be expended.

Lynn.—At a meeting of the Town Council the Town Clerk said when the original notice was given for the electric lighting provisional order a little clause was overlooked, and it was now necessary to confirm it. Mr. Savage said he understood that the cost would not be more than £50, but the other day he found that the cost would be £200 at least, and some said it might be £400. If up to the present they had only spent £100 he thought they had better drop it altogether. The Town Clerk said he asked his parliamentary agents what the cost would probably be and they said £200, and he mentioned that at that time. Up to the present four-fifths of the expense had been already incurred. Mr. Floyd pointed out the necessity for going forward, or they cleared the way for a private company to step in, which they would regret. Twenty municipal authorities had gone in for electric light and some of the results were very remarkable, while no serious loss had occurred even on the first year's working. It had been a financial as well as a lighting success. The order was confirmed.

Digitized by Google

Maidstone.—At the Town Council meeting the Mayor moved that the consideration of the Electric Lighting Committee's report be deferred for another fortnight. He had received a requisition to call a town meeting to consider the electric lighting question, and on account of this he thought it was advisable they should postpone the consideration of the committee's report for another fortnight. Mr. Cox seconded the resolution. Alderman Ellis observed that the electric lighting question was getting rather old. It was 12 months ago that the Council instructed the committee to see if they could dispose of the order, and now that they had got a report recommending certain steps to be taken, it could not, for some reason or other, be discussed by the Council. If they would discuss the report, which had been dangling before them for the past month, there would probably be some reasons before the public meeting for the action which the Council had been taking in the matter. The resolution was carried.

Walsall.—The Baths Committee report read at the meeting of the Town Council contained a recommendation that the baths be lighted with the electric light, and that the tender of Messrs. Fellows and Wheatcroft for supplying and fixing the necessary fittings, in accordance with the specification prepared by the resident electrical engineer, for the sum of £120, be accepted. This was agreed to. The Electric Lighting Committee reported that the whole of the electric lighting plant continues to run in a satisfactory manner. The total number of consumers supplied on January 28, 1896, was 45, the number of units consumed during the four weeks ending that date being 5,230, and the income therefrom £130. 15s The length of mains laid is—low-tension, 2¼ miles; high-tension, 1¾ miles; pilot mains, 1¾ miles. The number of applications for supply received since January 31 is four. With the view to reduce the temperature in the Dragon Hotel transformer station, the committee had given instructions for the removal of the flue in connection with the heating apparatus to the Dragon Hotel Assembly Rooms to some more convenient position. The report was adopted.

Ashton-under-Lyne.—The Sanitary Committee have been requested by the Electric Lighting Committee to supply information relative to the erection of the refuse destructor, in order that the question of utilising the same in connection with the proposed electric light installation may be considered. The Highways and Tramways Committee reported at the Council meeting that the town clerk submitted a letter received on January 17 from the clerk of the County Council, in reference to the application *re* the Oldham, Ashton, Hyde and District Electric Tramways, asking for the views of the Corporation in respect to the provisions of the proposed provisional order enabling the promoters to place and maintain on any street or road posts and overhead electric wires for working the tramways. The town clerk was instructed to write in reply stating that the committee saw considerable objection to such posts and overhead wires, but expected, in the event of the application being proceeded with, to induce the promoters to erect such posts and wires on the most improved principles, and so that any objection thereto might be minimised as much as possible. The report was adopted.

Swansea.—The negotiations with the tramway company for the purchase of their undertaking have fallen through. It should be stated that this does not prevent the scheme of electric lighting and a dust destructor being carried out. Powers were obtained for electric lighting some years ago, and have not lapsed whilst the dust destructor is simply a question of public sanitation Sir John Jones Jenkins, M.P., was in communication with the Corporation on Tuesday on the subject concerning the points in dispute with the Swansea Tramway Company, and also, it is said, as to the possibility of acquiring electricity for driving the Mumbles trams. The letter from the tramway company was couched in the following terms: "60, Finsbury-pavement, London, E.C., February 17.—Swansea Tramways and Swansea Corporation.—Dear Sir,—I have submitted your letter to my clients, who are unable to alter their views as expressed in my letter of the 13th inst.—Yours truly, HUGH C. GODFREY.—To the Town Clerk, Swansea." On receipt of this letter the town clerk (Mr. John Thomas) wired instructions to his London agents at once to withdraw the Tramways Bill. It is stated that there is no possibility of the negotiations being reopened.

Whitehaven.—At the Town Council meeting the engineer reported as to progress made in laying new cable to Bransty, George-street, and Oakbank, and further correspondence between the engineer and Dr. Hopkinson. It was resolved that the engineer write to Dr. Hopkinson as soon as the repairs to the conductors were completed, and request him to come to Whitehaven and inspect and report to the committee on the whole system of conductors laid under Messrs. Siemens's contract. Further correspondence with Messrs. Hathorn, Davey, and Co. as to delivery of the new pumping engines was read, and the engineer reported on the progress which was being made in laying the new mains to Kells-cottages. Councillor Musgrave said it was apparent that there would be a necessity to relay the whole of the single-wire cable before the term of Messrs. Siemens's contract expired. They were about to lay a substituted cable to the end of the North Pier, and one from the Grand Hotel to the top of Bransty, joining the portion already relaid there The committee expected Dr. Hopkinson to be at Whitehaven within the next fortnight, when they hoped to have his advice as to the course they should adopt with regard to the remaining faulty cables not yet relaid.

Dover.—The following letter was read at the Town Council Managing Committee meeting from the Electricity Supply Company: "Regarding our offer of the 27th ult., to supply incandescent electric lighting in some of the streets along the lines of our mains, we now observe that it has been stated, and not contradicted in the Council, that the Corporation are in honour bound to complete the contract they are entering into with the gas company. Under these circumstances we do not feel inclined to press our claim. For the present we are content that the Council should know that we are prepared to offer the same advantages to the town as our friends the gas company, and at as low a price. As, however, the efficiency of electric lighting is daily becoming more manifest, we expect that we shall soon hear again from you on the subject In the meantime we feel that we have earned the sympathy of the ratepayers of Dover. The price of gas has fallen, and public lighting of the streets been immensely improved; we leave it to the burgesses of Dover to judge if they would have had these benefits but for the presence of this company." The committee thought this was a very satisfactory letter, and unanimously decided to recommend the Council to seal the contract with the gas company.

Plymouth.—Interesting experiments have been made on tramcars belonging to the Corporation and the Plymouth, Stonehouse, and Devonport Tramways Company, electricity being substituted for oil as a lighting power. Several members of the Tramways Committee and the managers of the private company rode in the cars, and at the end of each trip the prevailing opinion appeared to be that the present mode of lighting the cars was not to be compared with the electric lamps. The experiments were made at the instance of the I. E. S. Accumulator Company, Limited, who fitted the cars with the light in such a manner that the source of the power was invisible to the passenger, the wires being carried along the top of the cars. Two Edison-Swan lamps were placed at each end of the car usually occupied by lamps, the accumulator being placed under the seats. The light enabled passengers to read a newspaper when sitting at any part of the car, and was not affected in the slightest by jolting, whilst there was of course, an entire absence of the disagreeable smell produced by oil lamps. It is claimed that after the initial cost the light is as cheap as oil, and as the outer casing of the lamp needs removing not more than once a year, there is also a great saving in labour. Special advantages with extra lightness and durableness are claimed for the accumulators with which the trial was made.

Castleford.—The lighting of the town by gas leaves much to be desired, and the Urban District Council have at last taken the matter in hand. At the last meeting, Mr. Latchem moved, "That the clerk be instructed to acquire all the necessary materials for the purpose of applying to the Board of Trade for permission to procure a supply of electric light for public and private consumption." In doing this, Mr. Latchem said he thought he was expressing the feelings of a large number of people in the town. The price of gas had been higher and more excessive than it ought to have been, and all the ratepayers of the town knew that the quality of the gas had been but very poor indeed. The matter had become a general complaint, and he thought a little consideration by the company was required. He was not going to reiterate what had been said at the previous meeting, but he must say that the matter had got to the extreme He had been a little surprised to find that towns further away from coalfields than Castleford paid a considerably lower price than they did. There was something wrong somewhere, and it was quite time the matter was taken up by the Council. He was aware some considerable time would have to elapse before they could have the better light installed, but if they got the order they could proceed at any convenient time to secure the much-needed remedy. On these grounds he moved the resolution. Mr. Wood seconded, but it was eventually decided to hold the subject over for another meeting, so as to have the matter well threshed out.

Kensington (London).—The Works Committee have reported to the Vestry that their attention had been called to the fact that a portion of the Fulham road has been opened by the Chelsea Electricity Supply Company, for the purpose of laying bitumen conduits for electric lighting mains without notice to the Vestry, the portion of roadway in question being situate in the parish of Chelsea, but maintained by Kensington under an arrangement with the Vestry of Chelsea. In reply to a letter addressed to them upon the subject by the surveyor, the company have signified their willingness to pay the cost of the restoration of the road, but the committee endorse the opinion of the surveyor, that works of this nature affecting the stability of a road maintainable by the Vestry should be carried out under their supervision; and the committee accordingly recommended that the vestry clerk be instructed to communicate with the company, intimating that the Vestry will object to any interference with roads under their control and management, without prior notice, and requiring them to take out a license before proceeding with the execution of any works. This recommendation was agreed to. The Works Committee further reported having had before them a letter from the Kensington and Knightsbridge Electric Lighting Company with reference to the Jandus arc lamp fixed as a trial on the refuge in Kensington High-street, by St Mary Abbott's Church, intimating that they would be willing to extend the trial, but expressing the opinion that the Vestry should pay them the cost which would have been incurred had the previous lighting been continued; and the committee recommended that the company be informed that the Vestry will be prepared to pay them the cost of the maintenance of an ordinary refuge lamp from February 4 and during the continuance of the trial of the Jandus arc lamp. This was also agreed to.

Glasgow.—The India Rubber, Gutta Percha, and Telegraph Works Company, Limited, Glasgow, Bradford, and Silvertown, Essex, have secured the contract for a complete installation of electrical machinery for the Glasgow Subway Company, Limited.

Digitized by Google

The contract includes four high-speed engines and dynamos, 13 electric power pumps, the lighting of 15 stations and trains, and the supply of power for the elevators. The current will be supplied from a central station in Scotland-street, and conveyed through tunnels by means of cables highly insulated with india-rubber. At a meeting of the Police Department of the Corporation, Mr. Primrose submitted the minutes of the Watching and Lighting Committee, which included the report, already published, on the electric lighting of the city streets. He dwelt upon the great superiority of the system adopted in Edinburgh compared with that of this city, and pointed out that its comparative cheapness was due to the policy which had from the first been pursued consistently and persistently by the Edinburgh Corporation of making popular the electric light. Mr. R. M. Mitchell was not prepared to accept fully the rosy report of the Edinburgh deputation, as important particulars on some points had been withheld—the fact, for instance, that the lamps were put out at 12 o'clock at night, while here they were kept burning all night. The cost of the light in various cities which he quoted led to him to believe that it was not so bad as it had been painted Dr. Colquhoun contended that the failure was due to the initial blunder of adopting the low instead of the high tension, in consequence of which two stations were necessary in place of one, and that in one the machinery and staff were kept idle all day. The report of the committee was adopted, and the matter remitted back to them to consider and report as to what measures are necessary to improve the system. In view of the report and adverse criticism by the Watching and Lighting Committee on the system of the electric lighting in Glasgow as compared with that successfully carried out in Edinburgh, a meeting of the sub-committee on electric lighting has been held to consider the position of matters. It was ultimately agreed to co-operate with the Watching and Lighting Committee with the view of devising means to improve the lighting.

Torquay.—At a special meeting of the Town Council the Electric Lighting Committee recommended that application be made to the Local Government Board for sanction to borrow £22,300 for the purpose of proceeding with the electric lighting of the borough. The committee also presented a report from Mr. W. H. Trentham, M.I.M.E., who estimated the cost of plant for 4,000 16-c.p. lamps and 70 arc lamps, with the proper reserve power, as follows: three boilers, including setting, £2,031; six engines, steam-piping, etc., £3 815; dynamos, exciters, accumulators, switchboard, etc, £4,320; 70 arc lamps and posts, £1,260; mains, transformers, street work, etc., £5,197; chimney, converting buildings, etc, £1,300; consumers' connections, meters, etc., £1.500; extension to Lincombe and Warberry districts, £2,147; contingencies and engineer's fee, £2,156—total, £23,716. The revenue per annum, charging the current at 6d. per unit, and taking the consumption at the very moderate rate of 13 units per 30 watt or 8-c.p lamp, would amount to £4 322, or, adding £519, the cost of gas lamps in roads, gardens and pier, where it is proposed to substitute arc lamps, the total revenue, with £150 for meter rents, would be £4,991. On the other hand, on the presumption that the destructor would give the power estimated—namely, 80 h.p.—the working expenses certainly should not exceed 2½d. per unit, which, including carbons for arc lamps and labour of trimming them, would be £3,234, or, adding interest and sinking fund, a total of £4,595, showing a net profit of £396. If, however, to be perfectly safe, they took the destructor as giving one-half the power above estimated, the working expenses, including interest and sinking fund as before, would be £4 895, clearly demonstrating that when the plant was fully loaded, they would get the light from the 70 arc lamps practically for nothing, even if the destructor would not perform what was claimed for it Alderman Kerswill, moving the adoption of the report, said the Council had already decided to retain the installation of electricity in their own hands. Therefore there would be no question in the future of paying something like 60 per cent. to buy back powers they had allowed to get into other hands. The lighting of the borough was already a big question and it would be greater in the future. The fact that some electrical companies were supplying boroughs with light at cost price should be a hint to gas companies to make an allowance to large consumers like the Corporation. Their provisional order had nearly expired, so they must now take action in the matter. Alderman Mortimer seconded, and the motion was carried by 14 votes to 4.

Belfast.—At the half-yearly meeting of the tramways company, the chairman referred to the contemplated use of electricity as a motive power for the tram system in Belfast. Electricity, he need hardly say, was fast coming to the front, and the tendency of all tramway companies was to alter their lines from a horse to an electric system. The fact was placed beyond doubt that in various cities on the Continent and in America the electric tram system was working in the most satisfactory manner. The directors, seeing what was taking place elsewhere, and what the general movement was in the tramway world, resolved to go carefully into the question. Having done so, they had deemed it advisable to deposit a Bill in Parliament taking powers to enable the company to apply electricity to the Belfast tramways. If they could not agree with the Corporation the Bill would be dropped, because the company had no desire to fight against the Corporation. In the event of both parties disagreeing, then this matter of electric tram power must be left over for a later period, when they would be more likely to see their way in adjusting their differences. He hoped, therefore, that the company on the one hand, and the Corporation on the other, would find no difficulty in coming to a settlement, in which event the Bill would be proceeded with this session. Mr. Wrigley asked if the directors had come to the conclusion that the electric system would be cheaper than the one now in use. The Chairman said the directors were certain that it would be cheaper; otherwise, he need hardly say, they would not have recommended its adoption. The directors had visited various places where electricity for working tramcars had been adopted. One of them (Mr. Murphy) had been to America, and he, with their secretary (Mr. Glenn) and their manager (Mr. Nance), had been to the Continent to acquaint themselves with the various systems. From all that they could learn, and from what had come within their observation, they had no doubt that the overhead system was the best to adopt. It was one of all others that would pay well, and it would effect a considerable saving over the working of the present system. These were the main considerations which weighed with them in recommending it for a city like Belfast. A special general meeting of the proprietors of the company was afterwards held, when the proposed Bill, entitled "A Bill to confer further powers upon the Belfast Street Tramways Company, and for other purposes," was submitted. The Chairman said that the meeting approved of the proposed Bill, and Mr. Fry seconded the motion. In replying to the questions, the Chairman said it was absolutely necessary to progress with the times, and they had to take into consideration the very manifest advantages which electricity had over horse power. With regard to the overhead system, the only difficulty which he apprehended against it was the presence of the supporting posts or poles *en route*. These, he pointed out, might easily be made of such an ornamental character as to deprive an objection of this kind of any force which otherwise it might possess Posts of this description would certainly be infinitely more desirable than the intolerable telephone and telegraph posts with which they were more or less acquainted. He did not think the Belfast people would, by reason of this objection, be greatly prejudiced against the electric tramway system. The motion for the Bill was agreed to. The Electric Committee have reported that the assistant engineer had attended and submitted applications for current supplies, some of which the committee were obliged to decline owing to the very great distance from the central station. They expressed the hope that within reasonable time the Corporation would establish a large generating station which would be capable of supplying the entire needs of the city.

Swansea.—A special meeting of the County Borough Council was held on Friday afternoon to receive the report of the last meeting of the Electrical Committee and the modifications offered by the committee to the tramway company in reply to their demands. The following letter from the solicitor to the company was discussed for two hours: "Your letter of the 10th inst has been carefully considered by my clients, who desire me to point out to you that the company has at no time shown any desire to depart from the original understanding as contained in the report of the Tramways Committee on October 31 and the letter from the secretary of the company of November 8 last. In the letter the secretary was careful to provide for 'the costs and other expenditure which must be incurred in carrying out the operation,' and which could not at that time, of course, be definitely defined, but particulars of which have since been given to the committee The company has no intention to apply any portion of the purchase-money towards return of capital to the shareholders, and will raise no objection to the application of the money being limited to the objects defined in the original proposal of the committee as modified by the letter of November 8 last Nor would there be any objection to agree that any portion of the purchase-money which should be left in the company's hands as working capital should be redeemed on the 21 years basis instead of 30. The company will also agree that any motors and cars provided by the Corporation shall be paid for on the 21 years' basis, provided that the company shall be at liberty to provide any of these cars if they elect so to do, in which case the cars would be the property of the company, and would be taken over by the Corporation on the same terms as the cars to be provided for the existing lines. The company cannot agree to pay for the cost of any plant necessary for the supply of the current, whether accumulators or transformers. They have no knowledge as to what the cost of these things may be, but it was agreed from the first that the current should be supplied to them ready for use and the price was fixed on this basis. I understand from your letter of the 6th inst. that the costs were to be divided between the Corporation and the company. The present proposal seems to be rather against my clients, although probably the difference may not be very great. With regard to the Mumbles Railway, there will be no objection whatever to the terms proposed, provided that the Corporation can make the arrangement which you suggest as feasible with the railway company. It seems to me, however, that this would more probably form the object of a separate agreement. It does not appear reasonable to the company that the purchase of the rolling-stock at the termination of the lease should be conditional on its being kept in a state of repair to the satisfaction of the borough surveyor. The rolling-stock is only to be taken at a valuation, and it is obvious therefore that the price will depend upon the condition of the material at the time of purchase. If however, the company should call upon the Corporation to provide any rolling-stock, the company would not object to the borough surveyor having power to call upon them to repair the same as and when required. If the committee should under the present circumstances recommend the Town Council to withdraw the Bill, the company, while regretting the result, will feel that they have done everything in their power to loyally carry out the understanding between themselves and the committee." The committee resolved to adhere to its recommendations, with the following variations: to alter the original

Digitized by Google

expenses on which the £32,000 be expended, so that it can comprise (1) the purchase of cars and motors, (2) alterations of depôt, (3) payment of all reasonable costs incurred by the company in connection with this matter. Another variation was that all questions in dispute be subject to the arbitration of the Board of Trade, and another that the electricity supplied be measured from the transformer. It was decided that unless these terms as altered be accepted by Monday, when the Bill comes on for first reading, the Bill be withdrawn.

PROVISIONAL PATENTS, 1896

FEBRUARY 10.

2944. Improvements in electromagnetic instruments. Herbert Watson Sullivan, 29, Ladbroke square, London.

2964. An improved system of wiring for electric installations. Robert Cornelius Quin, 18, Hamilton-road, Brighton.

3022. Improvements in and relating to the electrodes of secondary batteries. Henry Harris Lake, 45, Southampton-buildings, Chancery-lane, London. (Hubert John Tudor, Belgium.)

3032. New or improved self-acting electrical signalling apparatus for preventing collisions on railways. Heinrich Otto Krapf, 115, Cannon-street, London (Complete specification.)

FEBRUARY 11.

3071. Improvements in and relating to dynamo-electric generator and motor collecting brushes. George Edenson Dorman, The Hawthorns, Newport-road, Stafford.

3082. Improvements in armatures for induction motors. Abe Lincoln Cushman, 52, Chancery-lane, London. (Complete specification.)

3083. An improved ceiling rose and attachment therefor, chiefly applicable for electrical purposes. Robert Walter Braham, 60, Red Lion street, Clerkenwell, London.

3091. Improvements relating to the composition of the filling paste of accumulator batteries. Richard Linde, 18, Buckingham-street, Strand, London. (Complete specification.)

3092. Improvements in controllers for electric motors. James Devonshire, 70, Chancery-lane, London. (William B. Potter, United States.) (Complete specification.)

3093. Improvements in controllers for dynamo-electric machines. James Devonshire, 70, Chancery-lane, London. (Walter H. Knight and John W. Darley, jun., United States) (Complete specification.)

3094. Improvements in regulating phase relation of alternating currents. James Devonshire, 70, Chancery-lane, London. (Ernst J Berg, United States) (Complete specification.)

3096. Improvements in apparatus for regulating the tension of alternating electric currents. John Imray, 28, Southampton-buildings, Chancery-lane, London. (La Société Anonyme pour la transmission de la force par L'electricité, France)

3133. Improvements in and relating to electric clocks. Jacob Wiesner and Albert Witzel, 6, Lord-street, Liverpool. (Complete specification.)

FEBRUARY 12

3151. Improvements in arc lamps. Annie Taylor Schmidt and Frederick Thomas Schmidt, 12, Cherry street, Birmingham.

3213. Improvements relating to treating or flashing filaments for electric incandescent lamps. John Hadden Douglas-Willan and Frank Eustace Wilkins Bowen, 24 Southampton-buildings, Chancery-lane, London.

3224. Improvements in or connected with culverts or conduits and insulators for carrying electric conductors, more especially intended for carrying underground bare electric conductors. William Harding Scott, 47, Lincoln's-inn-fields, London.

FEBRUARY 13.

3235. Improvements in electric cranes. Edward George Fiegehen, Stafford Lodge, Ampthill-road, Bedford.

3256. Improvements in electric cables. George Hinde Nisbett, 15, Water-street, Liverpool.

3322. Improvements in electric batteries. Josef Fuchs and Louis Thiemann, 18, Southampton-buildings, Chancery-lane, London.

FEBRUARY 14.

3350. Improvements in coin-freed apparatus for administering electricity. Karl Rudolph, 18, Southampton buildings, Chancery-lane, London.

3359. Improvements in electrical furnaces for volatilising metallic and other ores. Ernest Bailey and John Dunn, 10, Lorne-terrace, Maryhill Glasgow.

3361. The electro-plating of iron and other metals and alloys, and the electro-reduction of metallic iron. John Kirkwood, 2, Carson-street, Edinburgh

3375. Improvements in electrical contact devices for clocks and the like. Thomas Smith Paynter and George Crockroft Walker, 73, Wroughton-road, London,

3394. Improvements in electric glow lamps. George Webb, jun., and Leonard John Underwood, 77, Chancery-lane, London.

3409. Improvements in or connected with recording electric meters. Arthur Wright, Norfolk House, Norfolk street, London.

FEBRUARY 15

3441. Improvements in or connected with or to be used with telephones. James Hunter Bennet, 6, Lord-street, Liverpool.

3478. Improvements in switches for controlling glow or incandescent electric lamps when used in conjunction with arc lamps. William James Davy, 40, Chancery-lane, London.

3481. Improvements in dynamo-electric machines. Sebastian Ziani de Ferranti, 27, Charterhouse-square, London.

SPECIFICATIONS PUBLISHED

1890.

16889. Electric motors. Kennedy. (Second edition.)

1891.

584. Dynamo-electric motors. Hutin and Leblanc. (Second edition)

1894.

8961. Electro-chemical decomposition. Carmichael. (Second edition)

1895.

1698. Electric current regulators. H. and R. Niewerth.

2182. Incandescent electric lamps. Attree

3076. Telephone and telegraph systems. Lake. (Shea and another)

NOTES.

City Technical Lectures.—Mr. W. H. Preece, C.B., is to be one of the lecturers in the Carpenters' Company's course of lectures on subjects connected with architecture and building at Carpenters' Hall.

Highbury Quadrant Association.—A lecture was given by Mr. P. P. Kipping, of the National Telephone Company, last Monday at Highbury-quadrant on the subject of the latest development of the telephone and telegraph.

Burmese Telegraphs.—Replying to a question of Mr. Yerburgh's in the House of Commons, Lord G. Hamilton said he had no information of an intention on the part of the Government of India to extend their Burmese telegraph system beyond its present terminus at Kieng Tung.

Finsbury Technical College.—A course of four lectures on "Recent Discoveries in Electro-Optics" is announced for delivery by Prof. Silvanus P. Thompson at the Technical College, Finsbury, on Thursday evenings in March. The lectures will deal with the experimental work of Hertz, Lodge, Tesla, Lenard, and Röntgen.

Iron and Steel Institute.—For the autumn meeting of the Iron and Steel Institute, which is to be held at Bilbao at the beginning of September, arrangements have been made to charter one of the Orient Company's steamers to convey the members there, and to act as a floating hotel. The cruise will last a fortnight. The annual meeting is fixed for May 7 at the Institute of Civil Engineers.

Theatrograph.—Mr. R. W. Paul's theatrograph is to be shown at the Royal Institution this (Friday) evening. The apparatus is one for the successive projection, by means of a lantern, of instantaneous photographs with such rapidity as to give an appearance of movement to the picture. The mechanism is so arranged that during the shifting of the picture the light is shut off. The apparatus is driven by a handwheel.

West Australian Telegrams.—The *Australian Mail* says that for more than a week Western Australia has been, so far as telegraphic communication is concerned, as quiet as the dead cities of the Zuyder Zee. Up to Tuesday nothing had been received since the 20th, and the news that came to hand then was despatched on the 18th. The interruption has been caused by storms and gales which have brought down the West Australian Government lines. Cablegrams, however, have now come to hand dated the 19th, so that communication is open again.

Tram-Wheels.—The February number of the *Street Railway Journal* sums up the recommendations which have appeared during the past year on the subject of electric tramway wheels. Our contemporary recommends a weight of 325lb. for a 33in. wheel. One wheel in every hundred should be tested for strength, and it should be specified that the wheels should be of uniform diameter within $\frac{1}{16}$in., and a guaranteed life of 40,000 miles should be demanded. Finally, flatting of wheels should be made an offence, leading to the prompt suspension of the motorman.

Motorcarts.—In his speech to the shareholders at the annual general meeting, the chairman of the Crystal Palace Company stated last week that it was intended to hold an international horse and horseless carriage exhibition, which would be of considerable magnitude. The grounds were well suited for experimental or competitive trials of the various kinds of motorcars, and the interior of the palace for a large show of carriages. The Lord Mayor had accepted the presidency of the honorary council, which also included the names of many noblemen and gentlemen of influence.

The Metric System.—Mr. W. M. Acworth has written to the *Times* pointing out that the Swiss Government have recently invited the countries parties to the Berne Convention—in other words, all the leading countries of the Continent of Europe—to a conference to discuss, *inter alia*, the introduction of a uniform gauge of screws based on the metric system. This is, according to the official document, intended to take the place of the Whitworth system, based on English measures, which is at present in use. Mr. Acworth points out that, if this is carried out, an obstacle due to our retention of a system different to the rest of Europe will be placed in the way of our foreign commerce.

A Chain Feeder Tramway.—A surface contact system for electric tramways has been described by Mr. Schnepf in the *Electric Railway Gazette*. In this system there is a chain lying in a trough covered by sectional rails, and under ordinary circumstances is not in contact with them. When, however, the car passes over the rail a magnet on the car draws the chain into contact with that particular section of the rail. The chain is connected to the feeders, and so makes that section alive while the car is passing over it. The sections are 8ft. long, and the rail is made of a non-magnetic metal. The chain is partly of iron and partly of brass. The commercial value of the system has not yet been demonstrated in practice.

Electro-Chemistry and Batteries.—According to the *Zeitschrift für Elektrochemie*, Liebenow's theory of electrolysis assumes that when a compound in solution can split up into ions simultaneously in different ways it will do so. In the case of the lead accumulator, owing to the low solubility of the lead salts and the low degree of dissociation of water, the lead ions and those from the water contribute little to the conductivity of the electrolyte, this being determined chiefly by the sulphuric acid. When a charging current flows through the accumulator only the peroxide and the lead ions in the solution will be set free, as they represent the least work of the current; but owing to their small number, they would soon be exhausted in the immediate neighbourhood of the electrodes, if the lead sulphate on the electrodes did not immediately go into solution after the deposition of these ions. When all the lead sulphate on one of the plates has been exhausted, a further current will electrolyse the water.

Technical Education.—The proposals of the Technical Education Board of the London County Council for the ensuing year involve a probable expenditure amounting to £120,000, of which £9,000 is for the equipment and £16,000 the maintenance of technical departments of polytechnics. The other items are £9,680 for Shoreditch, Wandsworth, and other technical schools; £20,000 for technical departments of public secondary day schools (including allowance for the fees of the Board's county scholars £7,500); £4,000 for higher education; £26,070 for county scholarships; £14,440 for art teaching (including art scholarships); and £8,985 for science teaching (including science exhibitions and pioneer lectures, technology, and manual instruction). In 1893-94 the Board's expenditure was £46,000; in 1894-95, £63,000; and in 1895-96, £91,000. One of the chief causes of the increase is the development of the Board's scholarship system, which has now nearly reached its limit, and is costing nearly £40,000 per annum.

New Incandescent Lamp.—A filament of somewhat complicated nature which it is proposed to use for incandescent lamps has been described in the German technical papers. The filament is made of hygroscopic asbestos paste. This, after being prepared in the form of a paper ·3mm. thick, is cut into strips 6cm. wide and impregnated with

Digitized by Google

a 30 per cent. solution of platinum chloride, then passed through a saturated solution of sal-ammoniac, after which it is dried in hot air and then heated in a Bunsen flame, which converts the platinum solution into a platinum sponge. It is then further impregnated with a 20 per cent. solution of magnesium chloride and heated, which process is repeated until the plate is covered with a uniform coating of magnesia, and it is finally dipped into a 10 per cent. solution of cerite nitrate. The magnesium coating protects the platinum, and as the light-radiating properties of the cerite metals are much greater than those of carbon, it is thought possible that such lamps will take less current. It is stated that the electrical resistance is much higher than that of carbon, and the radiating surface can be made much greater.

A Radical Departure.—Inventors and others who have devoted their attention to working out new methods of electric traction have occasionally produced curious results, and it will probably be admitted that the system patented in the United States by Mr. T. F. O'Connor, of New York, is, as the *Electrical Age* puts it, "a radical departure in design and operation from any hitherto devised." In Mr. O'Connor's system there is a conduit, but every tramcar has its own conductor all to itself. This conductor is reeled out from the power-house to the tramcar, which drags it along the conduit over anti-friction rollers. It is remarked that on long lines "it will be necessary or at least desirable to divide the line into sections." (Few will dare to dispute this.) In that case, when the car has passed off the section and done with its conductor, the latter is dropped and hauled back from the power-house end. Various advantages are claimed for this remarkable system, but, curiously enough, no use is made of the fact that the tramcar cannot run away under any circumstances. It seems a pity to omit anything that could possibly be said in its favour.

Lighthouse Communication.—In the course of a lecture delivered at the Imperial Institute on Monday by Mr. Charles A. Kent, secretary of the Trinity House, on the subject of lighthouse illumination, it was remarked that telegraphic communication with light-vessels was now an accomplished fact, and the more difficult task of connecting rock lighthouses electrically was being dealt with, the non-continuous system which was in successful operation at the Fastnet lighthouse on the south-west coast of Ireland offering special facilities in this matter. With this system the difficulties formerly inseparable from carrying a telegraph cable up an exposed rock, where it was subject to constant chafing, were overcome, the cable now terminating in the water 60 yards off, and the electric currents sent from the shore finding their way through this distance to two bare wires that dipped into the sea from the rock. In connection with this it may be remarked that the Royal Commission on electrical communication with lighthouses will probably issue a fourth report in the course of the next few months, and hopes to be able to make its final report before the end of the year.

Quadruplex Telegraphy.—An article by Mr. W. Finn has appeared in the New York *Electrical Engineer* on the subject of the "K R" law as applied to quadruplex circuits. Innumerable attempts have been made in the past to improve the working of the quadruplex telegraph system, which is still far from being a perfect one, especially when operated upon long lines. This is because there has not yet been in use a receiving apparatus with a sufficiently low time-constant. The distance to which it is now possible to operate quadruplex successfully is limited by the capacity, K, and the resistance, R, of the line, and the number of signals that can be transmitted per second depends on the product, K R. The applicability of this law to the quadruplex system, however, has not been generally known or appreciated. Mr. Finn suggests that for each of the improved systems in use the value of K R should be found and serve as a standard for determining their working capacities and the distances. He made two such measurements, and concludes that it may be considered fully established that when the K R equals 10,500 it is an excellent working quadruplex circuit, and when it is equal to 35,938 it is an impracticable circuit for quadruplex working.

A Novel Ladder.—The *Elektrotechnischer Anzeiger* reproduces from a Tokio paper a diagram of a new kind of ladder adapted for telegraph and telephone poles. A detailed description is wanting, but it appears that the ladder is constructed upon the principle of the lazy-tongs, so that it will shut up into a small space, and can be easily carried out. When it is wanted it is pulled out, and cross-pieces rapidly fitted on to pegs so as to form a horizontal diagonal to each of the parallelograms of the lazy-tongs serve the purpose of steps, and at the same time render the structure rigid. Hooks are attached at the top to pass over the cross-piece of the telegraph mast. It is understood that the author of the design is Mr. S. Kanda, a professor in the School of Telegraphy at Tokio. From another source it appears that the particulars given in the Japanese paper the *Electrical Friend* describe the ladder as entirely constructed of hard oak. The length of the ladder varies from 12ft. to 18ft. when extended, and is only 2ft. when folded up. The thickness is about 3in., and the width about 1ft. The whole ladder could be put in a box of 600 cubic inches. Work of this kind is one of the Japanese strong points, and the contrivance may very possibly prove a useful one.

A Wire-Thief's End.—The following is taken from the columns of the New York *Electrical Engineer*: "While stealing fully-charged electric light wires in Newark a man named J. B. Gove received a shock while on a pole 25ft. above the sidewalk, and fell. His skull was fractured, and he died instantly. A companion engaged with him in the thefts disappeared. His identity is unknown. The two men were thoroughly equipped as linemen, and early in the night stopped with a horse and wagon, which contained a ladder, some tools, and a quantity of wire, in front of 298, Belleville-avenue. They took the ladder to a pole, and Gove ascended. He had cut one strand, and was working on another when he gave a cry, threw up his hands, and fell head foremost, landing on the block pavement. The other man ran to him, seemed to realise that he was dead, took Gove's watch from his pocket, jumped into the wagon, lashed the horse, and drove away before the astonished onlookers could interfere. A physician and policeman were summoned, and an examination showed that Gove's left hand had been badly burned by the wire. His skull was fractured, and his legs and other bones in his body were broken. It was learned that Gove formerly worked as a lineman in Atlantic City." No particulars are given as to the current or voltage. Up to the present it is believed that it has not been found necessary for companies in this country to take into calculation the danger of having their line stolen.

Lighting Drapers' Shops.—It has been pointed out in the *Drapers' Record* that more fires occur in drapery establishments than in any other class of business houses. It is not to be wondered at, therefore, that insurance companies are somewhat shy of taking such risks, even at increased premiums. With regard to minimising the fire risk incidental to a gas-lighted shop-window full of highly-inflammable materials, our contemporary refers to the practice of lighting the gas with an unguarded taper when

Digitized by Google

a gas-lighting apparatus of a perfectly safe character is readily obtainable, and ought to be in universal use, and adds: "One of the greatest advantages of electric lighting has hitherto been supposed to be its freedom from dangers of this sort. The incandescent wires are completely covered by a glass case, and no taper is required for their ignition. These are advantages which it is impossible to gainsay, yet it is beginning to appear that they are not absolute but only comparative. Unless the fitting of the wires is thoroughly well done by experts, there is considerable danger of the fiery energy breaking out at unexpected and dangerous places. The only effectual way, therefore, to reduce the chances of fire to a minimum is to exercise the most scrupulous care in the choice of methods of lighting and their practical utilisation. We do not pretend to decide which is the best method under all circumstances, but certainly half-shielded gas-jets and quite naked tapers ought by this time to be things of the past."

Light Railways.—Mr. W. J. Brewer, in the course of a paper read at the Imperial Institute on the subject of light railways, held out the expectation that improvements would be forthcoming in rolling-stock and motive power to meet the requirements of feeder lines. By the aid of electricity it would be possible to supply both power and light, not only for the lines, but for the towns and villages on their route. The lines would be a means by which a system of telegraphs and telephones could be established at a slight expense, and they would add to the income. In his opinion, the new "autocar" in the interests of the agricultural classes would never do the work of a light railway, simply because no road could ever equal the surface of a rail. It was absurd to argue that these feeder lines should be of the same gauge as the main lines. The loads on the cars of the feeder lines could be so arranged as to be moved from the feeder car to the main-line car with the least possible amount of trouble or waste of time. As a motive power, Mr. Brewer took his stand by electricity. The materials comprising the car, motors, standards for carrying the electric conductors, rails, and other necessary equipment should be manufactured on the duplicating system, so as to reduce first cost and facilitate renewal. Points, crossings, signals, and signalmen could well be dispensed with, except at terminal stations. No greater mistake could be made than to load a light line by first initial cost. The speed he would suggest was from 10 to 12 miles an hour.

Forced Draught.—In the growing central station the question of increased boiler capacity is frequently a most troublesome one to deal with on account of limitations of space; and where the load line is particularly peaked, the solution of putting in more boiler power merely to carry the peak for a few hours is far from a satisfactory one, not only on account of the capital outlay and space occupied, but also because of the all-day decrease in economy of steam generation entailed. It is remarked by the *Electrical World* that the best solution, in many cases, is afforded by the storage battery, but a cheaper method consists of installing a fan and providing for forced draught. While with any air pressure increasing the capacity of the boiler plant to any significant extent there is a loss of efficiency in generating steam, yet as this would extend over but a comparatively short period, and the resultant efficiency may be greater than with natural draught and part of the boiler plant cut out during some hours. On the other hand, the effect of forced draught on the life of boilers must be considered, and this is a point that it would be well for boiler-makers to investigate. At present there seems to be no definite opinion in regard to the maximum air pressure that can with safety be used with various types of land boilers, and it is extremely desirable to know just where the limit lies, as well as the increase in capacity with various pressures of draught. Until this has been ascertained superintendents of central stations thinking of putting in a blower to assist the boilers over a peak in the load line should carefully consider the subject of the amount of pressure to use.

Telegraphs in Rhodesia.—The report of the British South Africa Company for last year (ending March 31), which has just been issued, gives the total length of telegraphic line under the control of the company south of the Zambesi as 1,354 miles. For the six months ending September 30, 1895, the receipts showed an approximate total of £7,631, and the expenditure £3,389. The construction of the Salisbury-Tete section of the line of the Trans-Continental Telegraph Company, Limited, has been delayed owing to exceptional difficulties, caused principally by the scarcity of native labour, the shortness of water due to prolonged drought, and the rocky nature of the country beyond Mount Darwin. Temporary through connection was made with Tete on October 22, and the communication has been maintained by joining the completed portion of the line from Salisbury to the Portuguese wire, which runs in a southerly direction from Tete by means of a temporary line 62 miles in length. It was originally arranged that there should be no public telegraph office of the company within Portuguese territory, but at the request of the local Portuguese authorities temporary arrangements have been made for the acceptance of telegrams at their local office at Tete. The Portuguese Government have erected a telegraph line from Chinde to Tete, and by using the Trans-Continental line, which runs through the latter place, the shipping community of Chinde is brought into touch with other parts of Central and Southern Africa, as well as with Europe and the rest of the world. The Blantyre section is completed, and the projected extension north of Blantyre has been commenced.

Electro-Harmonic Society.—This evening (Friday) there is to be a ladies' night. The following is the programme:—Part I.: madrigal, "Come, Let Us Join" (Beale), and part song, "Forsaken Am I" (Koschatt), Members of the South London Musical Club; song, "Come To Me" (Wadham), Mr. Henry J. Humm; violin, 'cello, and piano, "Allegro Animato" (from Trio in F) (Gade), the Misses Uhlhorn-Zillhardt; song, "Vainka's Song" (arranged by F. J. Whisham), Miss Emily Humm; 'cello solo, "La Cygne" (St. Saëns) and "Polonaise" (Popper), Miss Ethel Uhlhorn-Zillhardt; song, "The Scent of the Lilies" (Gerard F. Cobb), Miss Ethel Izard; part songs, "Must I Then Part" (Otto) and "Song of the Pedlar" (Lee Williams), Members of the South London Musical Club; humorous song, "The Tin Gee Gee" (Cape), Mr. Harry Jones. Part II: violin, 'cello, and piano, "Allegro Molto Vivace," from Trio in F (Gade), the Misses Uhlhorn-Zillhardt; song, "Queen of the Roses" (Sullivan), Miss Emily Humm; part song, "The Image of the Rose" (Reichart), and chorus, "A Hunting We Will Go" (Harding), Members of the South London Musical Club; piano solo, Mr. Alfred E. Izard; song, "Good-bye" (Tosti), Mr. Henry J. Humm; part song, "The Long Day Closes" (Sullivan) and chorus, "A Chinese March" (Otto), Members of the South London Musical Club; song, "Summer" (Chaminade), Miss Ethel Izard; humorous song, "Sheeny Man" (Rich), Mr. Harry Jones. The musical directors are Messrs. T. E. Gatehouse and A. E. Izard, and the concert takes place at 8 o'clock at the St. James's Hall Restaurant.

Attenuating Toxines.—Messrs. D'Arsonval and A. Charrin, of the Collège de France, have been investigating the action of high-frequency currents on bacterial toxines.

Digitized by Google

Former investigators in this direction, and notably Messrs. Smirnoff and Kruger, have confined themselves to continuous currents, in which case the results obtained are vitiated by the chemical action due to electrolysis. Mr. D'Arsonval and Mr. Charrin, on the other hand, have used high-frequency alternating currents, the toxine being contained in U-tubes plunged in iced water in order to prevent heating. As much as 223,000 alternations per second, and a current density of 250 milliamperes per centimetre were used, and the toxines worked with were those of diphtheria and pyæmia. The results were tried on guinea-pigs, and it was found that in every case the effect of the electrical action was greatly to diminish the virulency of the toxines, and that if carried to the proper limit the toxines, thus rendered harmless, sensibly augmented the resistance of the animals to infection of a similar kind, became, in fact, preventive vaccines. If this proves to be the case with the toxines of other bacteria, it will provide a much better method of attenuation than that at present in use, for though in a few cases this can be done by age or drying, it is usually necessary to pass the virus through the system of some unfortunate animal. A purely physical process would not only avoid the appearance of inhumanity, but would give a certain and measurable result instead of one always liable to be affected by unknown factors in the constitution of the animal operated on. Although when the frequency is extremely high the human body can be subjected to the action of an alternating current without any of the effects produced by one of more moderate frequency, it would be probably too much to hope that it might be possible to operate directly in this way on the bacterial products in the body of the patient.

The Official View.—In *El Telegrafista Español*, a journal which may be taken as representing with considerable ability the views of the Spanish telegraphic service, there has appeared a series of articles on the subject of the concession by the State to private companies of the right of erecting either urban telephones or interurban lines. This is considered to be altogether a dangerous proceeding from the point of view of the State, and, moreover, the revenue suffers. One of the conditions imposed upon the Interurban system was that its tariffs should be made uniform with those of the State telegraphs. This, however, our contemporary contends has not been done. Taking, for example, the published tariff of the Interurban system for the stations of Burriana, Castellon, and Villarreal it is remarked that telegrams from Valencia to these stations or from them to Valencia sent over the State lines pay 1·15 pesetas (11d.) for 15 words, while on the telephone system a three minutes' conversation can be had on payment of 75 centimos (7d.), and during those three minutes much more can be said than could be put into three telegrams. As a result, the telegraphic service to Burriana, Villarreal, and Castellon has fallen off so, that as regards the first two there have been days when no message has been sent, and this in spite of it being the time of shipping oranges, during which in other years one operator was not sufficient for the work of these offices. Our contemporary does not wish it to be supposed that it desires to oppose the telephone or to be counted among the enemies of progress in electrical matters, but contends strongly that the telephone service may and ought to be a State service, as it is in several other European countries. As to all this it can only be said that, however annoying it may be to a Government service to find itself undersold by a private company, it will probably be difficult to persuade the Spanish public, who get the advantage, to see the grievance quite so clearly.

Incandescent Lamps.—The *Electrical World* says that those who have followed closely the proceedings of bodies of practical men will doubtless have noticed the tendency toward the widest divergence of opinion in their discussions. Several examples of this were furnished at the recent Milwaukee meeting of the North-Western Electrical Association in the discussion on central-station economy with respect to incandescent lamps. One speaker advised central-station men to use 2½-watt lamps, and even to seek for 2-watt lamps, while another was cautious about recommending an efficiency as low as 3·5 watts. Superficially, the statement that 2½-watt lamps with a life of 300 hours are more economical than 3·1-watt lamps having a life of 600 hours has an appearance of reason, but, as shown by Messrs. Terry and Howell, it ignores several factors of the utmost practical importance in the present state of the incandescent lamp manufacture and of central-station operation. As incandescent lamps are made at present, the higher beyond a certain point the efficiency at which they are burned, the greater the deterioration in candle-power, and the less the ability to stand fluctuations in voltage. If, therefore, the voltage of currents were kept constant, it would not follow as a matter of course that the lamp of higher efficiency would give the best average result; while, under the conditions as to regulation in the majority of plants, the use of lamps of very high efficiency becomes impossible under the present methods of their manufacture. The discussion brought out very strongly the necessity of close regulation of voltage if satisfactory results are to be obtained from lamps of even 3·1 watts efficiency. It would be a great benefit to impress on lamp manufacturers and inventors the absolute need to the incandescent lighting industry, under present conditions as to competition from other sources of light, of a high-efficiency lamp that will have the same qualities as to life and maintenance of candle-power of, say, the present 4-watt lamp. Gas manufacturers in America have been urged by the competition of the electric light to improve their product in view of competition with the 16-c.p. incandescent lamp. Whether with the present class of filament and method of manufacture it is possible to hope for a 50-watt 24-c.p. lamp that will have a life with sustained candle-power of over 300 hours with the fluctuations of voltages encountered with alternating systems and many direct-current plants, seems a matter of some doubt. It is suggested, finally, that by working along new lines an improved lamp may be obtained.

The Telephone Service.—In the House of Commons on Monday last a question was put by Sir John Brunner to the Secretary to the Treasury, as representing the Postmaster-General, as to whether it was the intention of the Department, after the transfer of the telephone trunk lines from the National Telephone Company to the Department, to close these trunk lines at the hours of closing the various post offices, and thus to deprive a large body of subscribers of the convenience hitherto enjoyed by them of making use of the telephone at all hours of the night? To this Mr. Hanbury replied that, from the best information in the hands of the Post Office, it appeared that except in a few cases the telephone trunk wires were scarcely ever used at night, and the Department would not, therefore, be justified in going to the expense of providing attendance after the ordinary official hours. In the first instance, therefore, it was proposed that the hours for telephone business should be the same as for telegraph business, but the Department would give careful attention to the matter and ascertain where the requirements of the public would justify an extension of the hours. At many of the larger offices the telegraph service was open to the public all night,

Digitized by Google

and there, of course, the telephone service would also be open. Later on Mr. Tully asked what steps the Post Office proposed to take in reference to the numerous complaints as to the inefficiency and expensiveness of the telephone service supplied by the National Telephone Company, and whether it was the intention of the Government to terminate the monopoly of that company by taking over the entire telephone business, as was done in the case of the telegraphs. Mr. Hanbury replied that if it were proved that the company did not afford a satisfactory service, the Government would consider the advisability of establishing a limited competition. It was not the intention of the Government to take over the entire service before the expiration of the period of the license. It may be added to this that at a meeting of the Telephone Sub-Committee of the Glasgow Corporation it has been decided to ask the Postmaster-General to fulfil his promise of last year to appoint a committee to take further evidence as to the municipalisation of the telephone. As the result of the endeavours of the Liverpool Chamber of Commerce for permission for cablegrams to be transmitted by telephone after 6 p.m. to private addresses, the secretary of the Chamber has received a letter from the Postmaster-General's department intimating that arrangements to this end have been made with the Anglo-American, the Commercial Cable, and the Western Union Companies, and that the National Telephone Company are prepared to co-operate.

Telegrams to France.—Mr. J. Henniker-Heaton, having tried in vain to obtain from three successive English Governments returns of the telegraph and telephone business between England and France, addressed his enquiries to the French Government. The latter have given him what his own Government have refused, the Ministry of Posts and Telegraphs sending him the following letter: "In accordance with the request contained in your letter of the 9th inst., I have the honour to inform you that the number of telegrams exchanged between France and Great Britain amounted in 1894 to 1,216,545, containing together 14,417,260 words, which, at the rate of 20c. a word, represents a total receipt of 2,883,452fr. The number of the messages sent from France was less than the number despatched from Great Britain, France having sent only 548,154 telegrams, with 6,554,041 words, while she received 668,391 telegrams, containing 7,863,219 words. The total receipts were, under the provisions of the convention of June, 25, 1888, equally divided between the two countries, from April 1, 1894, whereas before that date France received $\frac{11}{20}$ths and Great Britain $\frac{9}{20}$ths of the proceeds. As regards the telephonic communications exchanged between Paris and London, they amounted in 1894 to the number of 45,115, which at the rate of 10fr. for each conversation, represents a total receipt of 451,150f. The number of conversations originating in Paris was less than that of the conversations started from London. The former only reached the number of 18,930, while the latter amounted to 26,185. The total receipts were, under the provisions of the convention of November 19, 1891, divided between the two countries in the proportions fixed for the division of the proceeds of the telegraph rates." In a letter to the *Times* Mr. Henniker-Heaton remarks: "Satisfactory as these returns are, there is a matter of grave complaint in connection with them—I mean the heavy charge for transmission of telegrams. The inland rate in Great Britain is ½d. per word; in France it is slightly less than ½d. (5 centimes). The rate between the two countries should be the sum of the two inland rates—that is, 1d. per word. Commercial readers need not be told of the immense stimulus to Anglo-French trade which this common-sense cumulative rate would administer. We can telegraph from London, by a submarine cable 100 miles long, to Jersey for ½d. a word, but to telegraph to Calais, by a cable 30 miles long, costs 2d. per word. So while a letter to Calais costs 150 per cent. more, a telegram to Calais costs 300 per cent. more than a similar letter or cablegram to an island nearly three times further away. From enquiries, I am disposed to think that if the British Ministry proposed a penny tariff the idea would be heartily welcomed in France."

Electric Lifebuoy.—The American papers contain descriptions of an electric lifebuoy which has been tested on board the lighthouse tender "Armeria," and favourably reported upon to the United States Lighthouse Board. The buoy consists of a ring mounted in a framework of metal tubing. The ring is normally in the plane of the frame. When the buoy is dropped into the water the ring on which the buoy floats turns so as to rest with its side on the water, and on so turning operates an automatic switch controlling the lights in the manner described below. At the lower end of the frame is the battery-box, containing the cells. To keep this perfectly dry inside, a moisture absorber is placed there with the cells. The box cover is easily removable and made watertight by a packing of rubber with wax or tar. The framework passes from the ends of the battery-box upward, meeting to form an arch above the ring. On top of this arch is the lantern, a glass globe covering one or more pairs of incandescent lamps. Electrical connection between these lamps and battery cells is through the tubes of the framework on both sides. On each side of the frame is a switch-box, containing the automatic switch controlling the circuit. The ring is mounted upon trunnions journaled in the switch-boxes. Where the trunnion enters the switch-box it is surrounded by a watertight stuffing-box to better protect the switch. The stationary contacts of the switch are secured to the frame and box, and the movable contacts are secured to the ring trunnions, but, of course, both sets of contacts are insulated from their supports. These contacts are so related to each other that the turning of the ring but a very small angle out of the plane of the frame will close the circuit and light the lamps, which will remain in circuit until the ring can be turned around nearly one complete revolution. This precaution is very important, because it ensures the continuous glow of the lamps in a rough sea. There is also a hand switch to the lamps and a bell. In reference to this the New York *Electrical Engineer* says: "A very interesting problem here is that of battery power. The lamps will be from three to eight volt, from ½ c.p. to 8 c.p., or more, and in every case will take about one ampere of current. The market can now furnish cells of which six in multiple series of three can glow continuously a couple of 1-c.p. lamps one hour. Connected in the same way, 18 such cells can glow these lamps three hours, and 36 of them can glow the same lamp six hours. More hours can be gotten by adding cells." After referring to the subject of recharging the accumulators, our contemporary adds: "There is now being designed a salt-water battery of such power that it will glow a strong light for several whole nights continuously when overboard, its capacity being large, without occupying much room.' The ordinary calcium phosphide "flare up" may not last quite as long as is desirable, but surely something less expensive and elaborate, not to say rough and ready, than the new buoy would be more likely to come into common use.

INTERCOMMUNICATION IN RAILWAY TRAINS.

BY J. PIGG.

"Every company shall provide and maintain in good working order in every train worked by it, which carries passengers and travels more than 20 miles without stopping, such efficient means of communication between the passengers and the servants of the company in charge of the train, as the Board of Trade may approve."

"To call the attention of the guard and driver, passengers must pull down the cord which will be found outside the carriage close to the cornice over the window of the carriage door. There are cords on both sides of the train, but that on the right-hand side in the direction in which the train is travelling is the one by which alone the communication can be made."

The first of these extracts is from Sec. 22 of the Act of Parliament 31 and 32 Vict., cap. 119, and, as will be seen, makes it obligatory for railway companies to provide such means of communication as, in the opinion of the Board of Trade, is efficient. The remainder of the section enumerates the penalties incurred by railway companies for neglecting to provide such communication and by passengers for unnecessary use thereof.

The second extract is a copy of the printed instructions to passengers for their guidance in using the communication between passengers and officials in charge of the train, and may be seen in almost any railway carriage in England.

Of the necessity for some means of communication there can be no possible doubt; the "separate cell" construction of English passenger rolling-stock makes it imperative.

No doubt the corridor train is the train of the future, and it has already obtained a slight footing in this country for certain classes of trains, but the change must, of necessity, be very slow on account of the large amount of capital invested in the existing class of carriages, and must, therefore, even if taken in hand at once, extend over many years before the conversion can be completed. Hence, it would appear that the necessity for means of communication will not immediately disappear, and it becomes of interest to consider what has been done towards complying with the requirements of the Act quoted and also in how far they may be regarded as satisfactory.

The most general mode of communication is by means of a cord stretched along the whole of the train, outside, and immediately over the carriage windows. One end terminates on the engine, where it is connected to the engine whistle; the other end terminates in the guard's van, where it actuates a bell. Instructions similar to those already quoted are posted in every compartment of the train.

The arrangement, which is wholly mechanical, is simple to work, cheap in construction, and does not require any special skill in its manipulation. The varying requirements of the train at different stages of its journey are easily met, the stock of apparatus to be kept on hand for repairs, etc., is simple in character, and the device, when used, is certainly effective. Its one vital defect is its comparative inaccessibility under certain circumstances which call for its use, but which need not be more particularly specified here. To put down the carriage window on one particular side and pull the communication cord would, in some cases, be quite impossible, however urgent the need, and, therefore, simply on account of this lack of easy use, the cord communication must be considered as comparatively ineffective, notwithstanding its numerous other advantages.

Considerable attention has been given to the provision of electrical communication as a substitute for the mechanical arrangement, and a few years ago a valuable prize was offered by the chairman of a southern railway company for a method of adapting the telephone to this class of work.

FIGS. 1 AND 2.—Diagrams of Connections.

The offer, so far as the writer is aware, was not taken up. The noise and vibration on a railway train in rapid motion are effectual obstacles to the use of such a delicate instrument as the telephone. Moreover, the possibility of conversation being carried on between any of the officials in charge of the train and a passenger is, in itself, in conceivable cases, evidence that the need is not urgent in the extreme. Passengers have constantly before them the fact that the use of the means of communication will be interpreted by the officials as indicating the necessity for bringing the train to a stand as quickly as possible. There is thus no need for an elaborate code of signals, or for means of carrying on a conversation; an arbitrary signal of the character of which there can be no doubt, is all that is required.

Railway companies have made some efforts in this direction, and as an illustration of the means adopted to meet the requirements of the service by substituting electrical for mechanical signalling appliances, the electrical part of the method in use on the South-Eastern Railway is shown in the diagrams.

In devising the method of working, considerable ingenuity has been exercised in making arrangements for testing the circuits at any time, for continuance of the alarm as long as may be necessary, and for locating the point from which the alarm has been given.

Digitized by Google

The arrangement shown in Fig. 1 is the normal condition for use by the passengers to give an alarm. On the engine a "make-and-break" bell and a six-cell battery are fixed, and in each van a switch, "shunt" bell, and six-cell battery are placed. In each separate compartment of the train a bell-pull is fixed, by which passengers are able to complete the circuit. The three batteries are opposed to each, as in Fig. 2, which is the arrangement of Fig. 1 simplified, and shows by the arrows the direction of the currents when a contact is made at any point between the two vans. Obviously, a "short-circuit" made anywhere on the train will cause all the bells to ring, and they will continue to do so until the circuit is broken again. By turning the switch handle to the right either guard is able to give an alarm if he sees the necessity, and is able to leave the bells ringing whilst he attends to such duties as the reason for the alarm renders necessary. By turning the handle upwards, the apparatus in that van is cut out of circuit and made inoperative.

It will be noticed that a defect in the apparatus does not, of itself, give any indication to that effect, and, consequently, the apparatus must be frequently tested in order that its condition may be known. The testing is done by the small push button shown above the switch.

The necessity for preventing mischievous use of the communication, and for locating the position from which an alarm has emanated, has been met by the mechanical connection of a small semaphore arm with the bell-pull, which, when the latter is used, projects from the carriage side. The bell-pulls are also arranged so that they can only be replaced by the guard after having been used. In this way it is comparatively simple to locate the point from which an alarm is given.

In some cases there is a separate semaphore arm and bell-pull to each compartment. In other cases a rod runs along the whole length of the carriage, and carries only one semaphore arm at one end. The pulls in this case are connected mechanically to the rod, and the use of any pull causes the rod to rotate and show the semaphore arm, and at the same time makes an electrical contact, which gives the alarm to the officials. The projecting semaphore arm indicates the carriage, and the position of the pull indicates the compartment of that carriage from which the alarm was given.

The system is fairly complete, and, since it has been in use some years, it may be assumed to meet the requirements of the company using it, but it would appear as if the first cost and maintenance would be much greater than for the usual cord communication.

If we contrast the electrical method just described with the cord communication, we find that if the former is more accessible owing to the number of points from which signals may be given and the greater facilities for reaching them, the latter holds an enormous advantage in the greater ease with which changes, rendered necessary by alterations in the composition of the train at different stages, can be made. The rock on which projects for electrical train communication have hitherto been wrecked is, as in train lighting, this breaking up of trains into sections at different stages of the journey, and the attaching of vehicles which may not be adapted for the particular method of communication employed on that train.

The rolling-stock of any one company is not confined to that company's lines alone, but is very frequently found on the lines of neighbouring companies. If all railways who interchange rolling-stock adopted one and the same method of electrical communication, nothing could well be said against such methods as are in use or have been suggested, provided all the rolling-stock were fitted up simultaneously. This last condition is, of course, not to be expected, and since existing or suggested methods of electrical communication do not seem adapted to work in conjunction with the existing mechanical arrangements, the former would appear, at first sight, incapable of fulfilling all the conditions of the railway service. From these considerations we are led to infer that any electrical system of train communication which will receive more than passing attention from railway officials must, of necessity, be capable of being used in conjunction with the system it is intended to displace, until the older and less efficient method is completely replaced. In the writer's opinion, it is to the persistent neglect of these requirements that the comparative failure of electricity for train communication is to be attributed.

Not the least requisite for a complete system of electrical communication is the organisation of the means of keeping the apparatus in a state of constant efficiency, more especially on lines which constitute part of the through routes of the country. An efficient system of testing the apparatus is, no doubt, very desirable, but, since the object of all testing is the detection of faults before they become apparent in the actual work for which the apparatus has been fixed, unless the testing is supplemented by an equally efficient means of remedying defects it becomes proportionally valueless. If all trains were run *en bloc*, or if trains always consisted of the same vehicles, and were subject to the same changes *en route*, the organisation of the maintenance would be comparatively simple, seeing that railway companies have linemen stationed at all important stations, and at many of less importance, whose duty it is to look after the maintenance of the company's electrical apparatus within a certain district. Unfortunately, as everyone acquainted with railway working is aware, these conditions are not attainable. The train service of a railway is constantly varying, and there is no certainty that any vehicle will always be available for certain work, or that any given number will always be available for the composition of a particular train. For these and similar reasons, it would appear that the organisation required for the maintenance of electrical communication in a constant state of efficiency will require to be very complete, and the details must be arranged with more than ordinary care.

It may be thought, from the tone of the previous remarks, that a somewhat pessimistic view of the prospects of electrical train communication has been taken. This is not the case, but it would appear from the considerations of the requirements to be met that any system, to secure general adoption, must proceed on radically different lines to those hitherto followed, and that the first thing to be done with the object of securing an acceptable system for general use is to fully understand and face the requirements of the service.

MUNICIPAL WORK AT COLOGNE.

RESULTS OF COMBINED WORKING OF WATER AND ELECTRIC LIGHT WORKS, BY MESSRS. C. P. FELDMANN AND ENGELBERT FROITZHEIM.

The details of the electricity works at Cologne were fully given in our recent issues (pages 89 and 120). As then explained, the municipal waterworks occupy an adjacent site, and by combining the electric station and the waterworks, considerable advantage has been obtained. In the first place, it was not necessary to acquire a special site for the electric station. The plans for gaining water would have necessitated a much larger area of ground than that required only by the buildings for the pumping plant. The wells are now arranged at distances of 50 metres (54·5 yards from one another, and this is the least distance allowable if the normal output of each well is to be maintained. If the distance between two adjacent wells is smaller, the areas from which they obtain water overlap so much that the total output is diminished, and, starting pumping from one well, the water-level in an adjacent well, not working, is lowered to a certain measurable degree. With 50 metres (54·5 yards) distance this mutual disturbance is but small; still, the total area of extraction of water by one well covers a radius of 200 metres (218 yards) diameter. Besides, if the surface water obtained satisfies the strictest sanitary requirements, it is necessary to have a considerable area free from all structures, as the drainage from the buildings might infect the water. The danger of infection may be considered as excluded as soon as the area of supply, which in this case embraces a radius of 200 metres (218 yards) diameter, is kept free from all houses, etc. For these reasons the waterworks required an area like the present one, even if the electric

Digitized by Google

station had not been combined with them. In spite of this fact, and in order to avoid any error as to the real earning power of the electric station, the latter indemnifies the waterworks by paying them a tax of 3,000 marks (£150, about) annually, which corresponds to the interest on about 100,000 marks (£5,000 about). For this sum, however, it would not have been possible to obtain an equal area in any part of the city.

In the second place, the combination has diminished the initial cost of both works. As mentioned in the preceding articles, the waterworks required a second boiler-house similar to the old one; this can be dispensed with by working both sets of engines from the large new boiler plants. The maximum output of the two works never coincides. The largest consumption of water takes place during the day and the summer months; the maximum output of the electric station is attained in the evening and during the winter months. The boiler plant is therefore worked at a nearly constant rate of steam production throughout the year—that is, the load is practically constant.

In the third place, therefore, the total costs of steam production are greatly reduced. These costs are made up of the outlay for fuel and for wages. The electric station works with a load corresponding to the whole number of lamps connected to its mains during 1·3 hours a day. As it is an alternating-current station, and runs continuously, its boilers have to be kept working without intermission with a widely varying rate of steam production. During the large number of hours of small load the loss would be nearly constant and rather high. Similar conditions would be obtained if the waterworks were working alone. How much these losses would have cost cannot be stated with regard to the electric station, as this has never worked alone, but they are clearly pointed out by the coal bill of the waterworks. Before erection of the electric station 526 kilogrammes (1,157lb.) of coal were used for 1,000 cubic metres (35,200 cubic feet) of water supplied; after erection of the station only 478 kilogrammes (1,052lb.) were consumed. As the output for the last year (and for the new works, of course) was 6,315,000 cubic metres (223,000,000 cubic feet), the total saving of coal makes 3,000 marks (£150, about). The total amount of fuel is distributed between the two works according to their daily number of horse-power hours. This distribution is made every day. It is not necessary to explain that the total wages of the firemen are less for both works than they would have been for each of them separately.

In the fourth place, the immediate neighbourhood of both works provides cheap and good water for condensing for the electric station. Had the latter been within the city, it would have been necessary either to erect and to work a special pumping plant or to take water from the supply pipes. In both cases the outlay would have been much higher than at present. It was very favourable that in the present case the whole work of raising water was divided, thus allowing the water to be taken (without reaching the total pressure) from the first reservoir. The water may, therefore, be sold at a low price, equal to the waterworks own costs for the work spent on it. The waterworks revenue from water used for condensing purposes is about 3,000 marks (£150, about) annually. The total earnings of the waterworks from the central station are therefore 6,000 marks (£300, about), or about 20 per cent. of the total outlay for coal, which amounts to 30,000 marks (£1,500, about) annually.

In the fifth and last place, the costs of administration are diminished by the combination. The work is superintended by an engineer, assisted by a second man, who does the writing. The latter keeps the wages books and stores, etc., and the lists of the daily output and consumption. The service is controlled by two foremen and a manager, the former watching over the day and the night shifts respectively. A doorkeeper notes persons and goods that enter and leave the ground; in addition, he works the weighing-machine and controls the total amount of coal introduced. The coal consumed is weighed in the usual way by the firemen. These latter, as well as the rest of the workmen, have to begin with the simplest work. Only strong young fellows are taken, who have to begin as helpers with handing in coal, putting out ashes, etc.; in due time they advance, and become helpers for the firemen, and afterwards firemen. In the same same way the engine drivers are educated, but they must have finished their apprenticeship in a smith or engineer's shop before entering the works service. These engine drivers have to work both sets of engines, so that sickness or strike are not likely to disturb the regular service to any great degree. The whole rooms for the administrative work, the doorkeeper, and the workmen are common to both works, thus forming another point of saving in first cost.

In this way the combination has proved successful for both works, and especially the electric central station has obtained financial results which make it one of the best working stations of Germany in spite of the short time of its existence.

THE "JANDUS" LAMP.

REPORT BY PROFS. HOUSTON AND KENNELLY.

We beg to submit the following results of our measurements of the candle-power and rate of burning of carbons of the lamp placed in our hands for examination. The lamp submitted to us is designed to operate on incandescent circuits of from 90 to 120 volts pressure. In order to determine the rate of consumption of the carbons, we operated the lamp daily from July 19 to August 1 last, making in all two runs of 50 hours each. We found the average rate of burning of the positive carbon to be 0·057in. per working hour, and of the negative carbon 0·015in. per working hour.

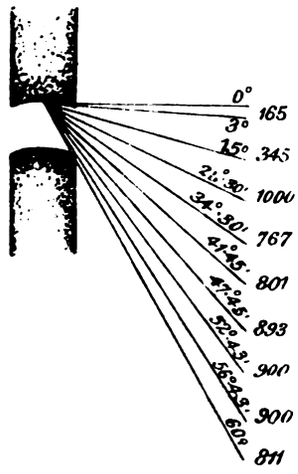

FIG. 1.—Jandus Incandescent Arc Lamp Test made by Prof. Edward Houston and Dr. A. E Kennelly through two clear glass globes.

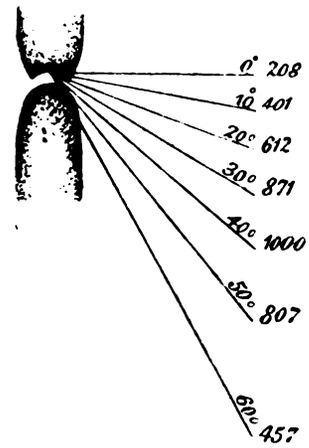

FIG. 2.—Average of 26 Ordinary Arc Lamps. Official test made by Wybauw with naked arc.

According to this rate, the positive carbon, which is 12in. long, of the solid "Electra" type, and ½in. in diameter, would last 210·5 hours; and the negative carbon, which is 6in. long, and also of the solid "Electra" type, would last 400 hours, assuming that the carbons could be entirely consumed. The lamp, therefore, requires to be recarboned only at comparatively long intervals. The average current supplied to the lamp from 400 observations was 5·60 amperes. The power consumed by the lamp at 110 volts pressure represents 616 watts, or 0·826 e.h.p. The pressure between the carbons of the lamp when in operation averaged about 80 volts, and the resistance permanently inserted in the lamp effected a drop of pressure of approximately 30 volts, thus enabling the lamp to be used on a 110-volt circuit. The apparatus may be regulated so as to carry the current strength and power absorbed, and we have observed one of your lamps taking an average current of 4·5 amperes. Owing to the comparatively large pressure between the carbons, one of these arc lamps can be inserted in a single-branch circuit across 115-volt mains, and, on the other hand, the arc obtained is a long one, and thus the shadowing of the positive crater by the negative carbon is largely avoided.

The lamp is simple in its mechanism and efficient in operation. It only employs a single magnet, which

Digitized by Google

regulates the position of the upper or positive carbon. We found the arc to be very quiet, and rarely to flicker. It is suitable for indoor as well as outdoor illumination. The carbons being completely enclosed, no sparks or hot carbon dust can fall from the lamp and set fire to inflammable material which might be placed beneath it. The lamp is provided with two glass globes, an outer and an inner. The long life of the carbons is due to the fact that the presence of these globes maintains around the carbons an atmosphere free from uncombined oxygen. In measuring the candle-power of this lamp, both of these globes were of clean and clear glass. The lamp was raised and lowered by a rope near the photometer, so as to measure the candle-power at different angles of elevation and depression. Our standard of luminous intensity was a Hefner-Altneck amyl-acetate lamp, and our secondary standard an incandescent lamp burning at an efficiency of about $\frac{1}{2\cdot5}$ candle per watt. The maximum candle-power observed in any position was 1,295 standard British candles. The following are the mean results of two sets of observations at various angles:

Angle of elevation.		Luminous intensity. (British standard candle.)
	− 25° 30′	141
	− 19° 30′	145
	− 8° 15′	177
Depression	3° 30′	189
	15°	396
	25° 30′	1,148
	34° 30′	869
	41° 45′	920
	47° 45′	1,025
	52° 43′	1,032
	56° 43′	1,035
	60°	931

Under the conditions above described the maximum candle-power may be taken at 1,300 British standard candles. During the tests for candle-power the lamp was operated under practically the same conditions of pressure and current as during the test for consumption of carbons.

SWINBURNE'S NEW VOLTMETERS, AMMETERS, AND WATTMETER.

BY W. PERREN MAYCOCK, M.I.E.E.

Swinburne's Electrostatic Voltmeter (Holt's Patent).—A plan of this instrument with dial removed is given in Fig. 1, and a side-sectional view in Fig. 2. Fig. 3 gives a separate sketch of the vanes and pointer. Q_1, Q_2, Q_3, and Q_4 (Fig. 1) are four quadrant-shaped brass cases, the form of which will be more clearly seen from Fig. 2, where a section of Q_1 and Q_3 is given. Q_1 and Q_3 are connected together, as are also Q_2 and Q_4, the position of the connecting brass strips being shown dotted at *w* and *w'* (Fig. 1). Q_1 is connected with one of the terminals and Q_2 with the other, the connection being through fine copper fuse wires enclosed in glass tubes. In the event of any sparking or arcing taking place between the differently charged parts of the instrument, the resulting current fuses these wires, and any short-circuiting of the mains to which it may be connected, as well as damage to the instrument, is prevented. These fuses are on the outside of the case at the back, and are thus easily got at for renewal. One of them is shown at F (Fig. 2), their position being shown dotted at F and F′ in Fig. 1. The parts of the instrument are mounted on a thick ebonite base (shown black in Fig. 2), and the surface between the quadrants is corrugated, as at C, C, C, C (Fig. 1), to increase the insulation and prevent leakage between the oppositely-charged quadrants. For this purpose also the terminals are very highly insulated, one being shown at T (Fig. 2): the terminal shank is enclosed in an ebonite tube, E T, and its inner end provided with an ebonite cap, E C. The position of the terminals and their ebonite caps is shown at T and T′, E C and E C′, in Fig. 1. The pointer, P, and vanes (of which there are two), V V′ (Fig. 2), are mounted on a light steel spindle resting on friction wheels, F W (Figs. 1 and 2). This kind of bearing, which enables the spindle to turn very easily and freely, is as follows: two small wheels with smooth sharp edges are mounted side by side in jewelled or highly-finished bearings, so that they overlap, but do not touch; the end of the spindle rests between and on their top edges. The front vane, pointer, and counterweight are shown in Fig. 3. The vanes and pointer are of aluminium, and to decrease their momentum and render the instrument more dead-beat, the former are perforated: their peculiar shape will also be noticed. P projects round in front of the scale, S, as shown in Fig. 2; the position of S is shown dotted in Fig. 1. It is obviously important that the instrument be set up perfectly level, and for that purpose a spirit-level, S L (Fig. 2), is provided. The instrument is adapted to the measurement of either direct or alternating pressures, and is made in various ranges—800 to 1,600; 1,400 to 2,600; and 1,800 to 3,200 volts being the ordinary. It can, however, be made to read up to 8,000 volts, and in a different form to 50,000 volts. Its action is as follows: As seen in Fig. 2 the vanes are in connection through the spindle and bearings with the quadrant Q_1, and thus Q_1, Q_3, and the

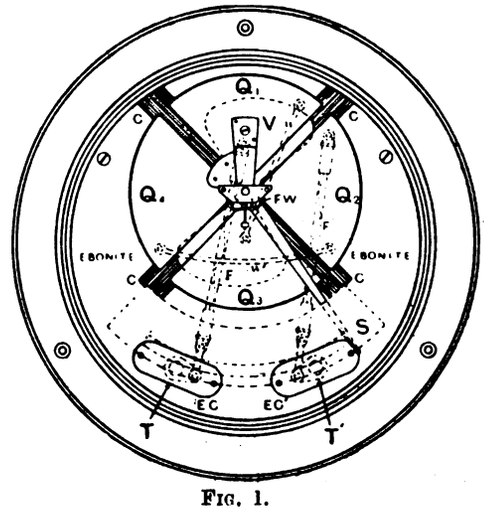

FIG. 1.

vanes are in connection with one terminal, T, of the circuit, Q_2 and Q_4 being joined to the other, T′. The zero position of the vanes is shown dotted in Fig. 1; it will there be seen that they project slightly from the enclosing quadrants. Suppose the terminals, T and T′ (Fig. 1), are connected respectively with the + and − points in a circuit, the pressure between which it is desired to measure: Q_1, Q_3, and the vanes will become + ly electrified, and Q_2 and Q_4 − ly electrified; the vanes will consequently be repelled by Q_1 and Q_3 and attracted by Q_2 and Q_4, against the force of gravity acting on the counterweight: the projection of the vanes when in the zero position will cause them to move round in a clock-wise direction, and the pointer will move from right to left. The same reasoning applies with

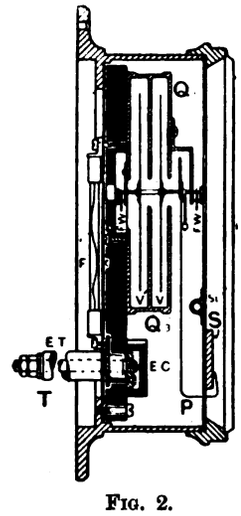

FIG. 2.

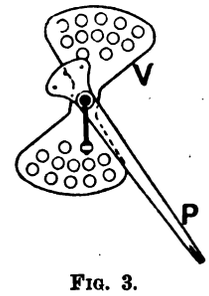

FIG. 3.

an alternating pressure, it being remembered that, though the electrification is rapidly alternating, the vanes, Q_1 and Q_3, are always similar in electrification, and opposite to Q_2 and Q_4.

Swinburne's "N" Type Voltmeters and Ammeters.—These instruments consist of a pair of astatic needles and a current-carrying coil: the principle of action is thus the same as that of an ordinary astatic detector. They are clearly only adapted for direct-current work, but by reason of their construction are claimed to be unaffected by neighbouring fields, and to be cheap. The interior of a voltmeter is shown in Fig. 4, the exterior being very similar to that of other instruments. B F is a brass skeleton frame, on which is wound a coil of fine wire, C, of about 800ω resistance; another coil, R, of platinoid wire and about 3,200ω resistance is joined in series with C, and the two are connected with the terminals, T and T′. The use of R is to reduce the current passing through the instrument, and to minimise any error due to the current heating the coil and increasing its resistance. The turns of the coil are opened out

Digitized by Google

at O to enable the needles to be put in place. The latter, one of which (N) can be seen in the figure, are of thin sheet steel carefully magnetised, and the poles being close together are little affected by external fields. The flatness of the needles and the closeness together of the poles (giving a nearly closed magnetic circuit) is the special feature of this instrument. The needles and pointer, P, as well as two counterweights, C W, C W′, are fixed to a steel spindle mounted in bearings, one of which (B) can be seen on the front of the coil. C W is used

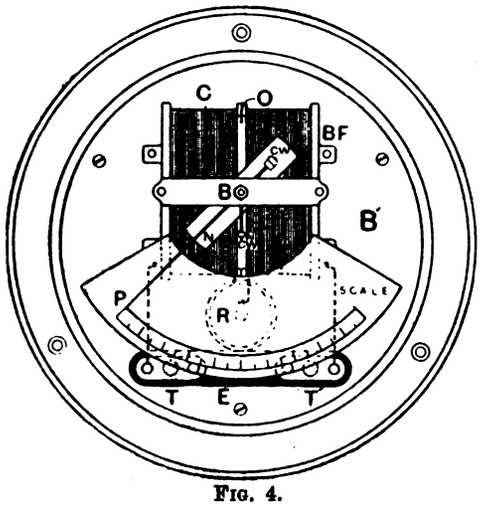

FIG. 4.

to balance the needles and pointer, while altering C W′ increases or diminishes the sensitiveness of the apparatus. The parts are mounted on a sheet-iron base, B′, and the terminals on an ebonite block, E, shown black. Voltmeters of this type are generally constructed for ranges up to 100 or so volts, but can, of course, be made to read to higher values. Fig. 5 shows an ammeter coil for this type of instrument. The winding consists of a single turn of copper strip carefully insulated from the brass frame. It is in two pieces, P and P′, joined in parallel; one joint is shown at J, the other being below. T and T′ are the terminals. For heavy currents the instrument is arranged as a shunt across a low resistance in the main circuit, so that the heavy main leads need not be led to and from the instrument.

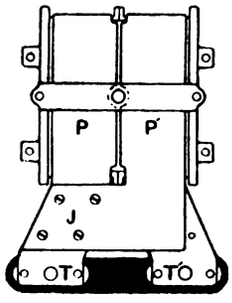

FIG. 5.

Swinburne's "Inductor" or "U" Type Instruments.—This type of instrument for alternating-current work, which may be fitted either as a voltmeter, ammeter, or wattmeter, is unique in principle, and though not complicated in construction, its action is somewhat difficult to explain clearly. I C (Figs. 6 and 7) is a square-shaped iron core built up of thin sheets of soft iron in two pieces, which are bolted together at the joints, J and J′, the larger sheets having a projecting piece, P. These sheets or stampings are insulated from each other with thin paper to prevent the setting up of eddy currents. A closed magnetic circuit is thus provided for the two coils, C_1 and C_2, which are of copper wire and joined in series, while the magnetic flux due to the third coil, C_3, completes its circuit across the air gap, G. C_4 is a coil of a single turn, three sides of which are made of copper strip, while the fourth side, which moves in the field gap, G, is of manganin, to retard the setting up of induced currents in it. C_4 embraces the iron core, I C, and is fixed to an arbor or spindle, together with a pointer, P, and counterweight, C W. The fixing of the parts to the ebonite base, E B, is clearly shown in Fig. 7. The terminals, T and T′, are like those of the electrostatic voltmeter above described, but they are unprovided with ebonite caps when the instrument is only used for low pressures, as in the accompanying figures. The action of the instrument is briefly as follows: The passage of an alternating current through C_1 and C_2 sets up a magnetic flux in the core which induces an alternating current in C_4. C_4 being movable, and one side of it being in a correspondingly alternating field due to C_3, that side will travel along the air gap, G, and C_4 and P will be rotated. C_1 is the same whether the instrument be used as a voltmeter, ammeter, or wattmeter; but the connection and winding of C_1, C_2, and C_3 differs in these various cases. In a voltmeter C_1 and C_2 are of copper wire (about ·02in. diameter), connected in series to the terminals, and of a low resistance. C_3 is of fine German-silver or manganin wire wound to a high resistance, and joined as a shunt to the termi-

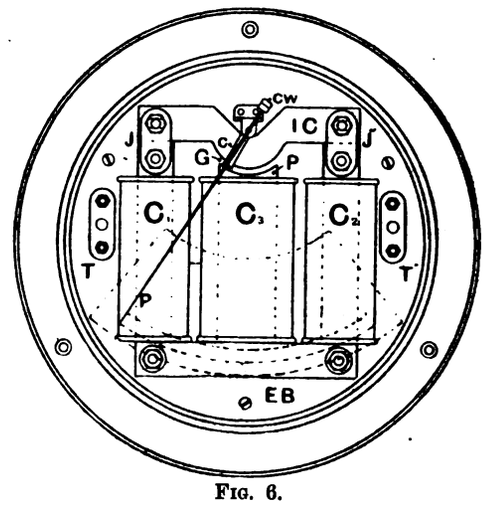

FIG. 6.

nals, T and T′. In an ammeter the connections are just the same, but C_1, C_2, and C_3 are wound with much thicker wire. In a wattmeter C_3 has a copper winding of low resistance, and is joined up in the main circuit; while C_1 and C_2 are wound the same as in a voltmeter and connected in series with two separate

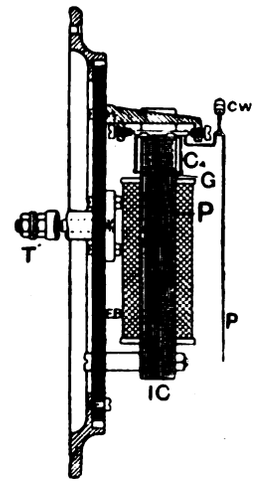

FIG. 7.

terminals. As before mentioned, the main current is sent through C_3, while C_1 and C_2 are connected as a shunt to that portion of the circuit whose power is to be measured.

ELECTRIC WELDING.*

BY T. SCOTT-ANDERSON.

It will perhaps be desirable to devote attention to two processes—(1) the one named in this country the Benardos system, and (2) that of Dr. Zerener, which is called the deflected arc method of welding. In doing so no injustice will be done to the earlier Thomson system if the writer refers the members to a paper on the "Thomson Electric Welding Process," read by Mr. Dobson at the Manchester meeting of the Society of Mechanical Engineers. A fourth, the Hoho-Lagrange system, may be mentioned, but as far as the writer's knowledge goes no plant on this method is yet working in England. The last-named process relies for its heating properties upon the following conditions: a wooden tank (lead-lined) is filled with acidulated water to a density proportionate to the voltage or electrical pressure used, one pole of a dynamo is connected directly to this inner leaden sheath, and the remaining pole is coupled to the bar of steel or other article

* Abstract of paper read before the Federated Institution of Mining Engineers, February 19, 1896.

Digitized by Google

to be heated; this system therefore needs the use of a tank or bath large enough to receive the metal which requires heating. The moment the bar touches the water electrolysis of the acidulated water is set up, the water is split up into its component parts, oxygen going to the leaden sheath, and hydrogen rushes to the bar of steel or other article being heated; these particles or globules of hydrogen cling to the metal, and form a complete gaseous envelope around it, so that the metal is actually no longer touching the water. The hydrogen sheath offers a large resistance to the flow of current, and the whole energy is thus transformed into heat. For case-hardening of small articles, for hardening and tempering of steel wire, knife-blades, and similar articles, the process may find useful employment; but where large masses of metal have to be treated the large expenditure of current would, in the writer's opinion, be prohibitive. One considerable advantage is, however, evident—viz., that the heating being effected under water no oxidation of the metal can take place. A continuous current at a pressure of about 200 volts is used for this process. The temperature, however, is not easily controllable, and the utility of the process appears to be confined to easily weldable iron or low-grade steel and to pieces of simple form.

The Benardos or Arc System.

In the Benardos or arc system the article to be operated upon is made to constitute one pole of the electric circuit, while a carbon pencil attached to a portable insulated holder, and held by the workman, constitutes the other pole, the electric arc (which is the heating agent of the process) being struck between the two poles thus formed. When steel or iron is being welded it is usual to make the carbon the negative pole, and the steel or iron the positive pole, but for other metals the poles are sometimes reversed. In welding lead, for instance, it is usual to make the carbon the positive pole. This process has during the last two or three years been considerably improved in detail at the works of Messrs. Lloyd and Lloyd, Birmingham, and elsewhere. In Sheffield there are eight plants doing most satisfactory work in various ways.

The method of working is simple, and is practically the same in all cases at Messrs. Lloyd and Lloyd's. Several low-tension continuous-current dynamos are used. During periods of light loads these dynamos are employed in charging a number of sets of Benardos accumulators or secondary batteries. At times of normal loads, the dynamos supply current direct to the welding shops. When extra current is required, provision is made whereby a large discharge from dynamos and batteries combined is obtained. In parallel, with the dynamo and batteries as many welders or welding machines can be connected as may be desired, and every workman is able independently to vary his current and pressure to suit the work in hand at the moment. One terminal of each welding system is connected by means of a flexible cable to a carbon pencil held in an insulated holder, which is in turn held by the workman, while the other terminal of the system is connected to the table on which the work lies, or to the work itself. The special advantage of this arrangement of resistances and accumulators is that it admits of wide limits of variation of current and pressure to suit the different classes of work which may be in progress.

In passing from this part of the subject, we come to a more important one—viz., what has been done by the Benardos system—and an explanation of the simplest and cheapest method of doing similar work. A slot-link of the reversing engine broke, and stopped the mill. The broken pieces were placed together and electrically welded at the points of fracture, after which the link was fitted and erected, and the engine with the repaired slot-link was running again within one hour from the time of original breakdown. This slot-link continued to work for ovsr 12 months without trouble, and until the engines were eventually removed. A shaft with flange coupling keyed on one end. The continual reversing of the engine to which this shaft belonged, together with the heavy nature of the work done, started the keys, which in turn damaged the edges of their key-beds, and also the bed of shaft coupling. The damaged parts were welded up again, and the bed of the shaft coupling turned, new keyways cut, and coupling keyed on as before. This example is only one of several shafts which have been treated in the same way—many of them being done *in situ*, and always with excellent results. Apart from the general work done by the Benardos process in the repair of slightly defective steel castings, many other instances might be cited where repairs of a similar nature to those already described have been done, such as welding in the teeth of cast-iron wheels which have been broken while working, without removing the wheels from their shafts, but one more example must suffice before proceeding to treat of the application of the process to boiler repairs.

Cutting and Boring.—Another very simple application of the electric arc is that of cutting and boring metals roughly to shape. In work of this kind the same methods of procedure apply as in all the other cases cited—viz., that the article to be cut is made to form one pole, and the carbon pencil the other pole. Under these conditions, if the carbon pencil be brought into contact with the metal to be operated upon, an arc is immediately struck between the carbon pencil and that part of the metal in contact with it at the time, with the result that the metal is instantly melted in the immediate vicinity of the arc, and may be allowed to flow away as it is melted. In this way holes may be pierced in steel, iron, or other plates with great rapidity, and by gradually moving the arc the holes may be elongated into slits of any required length or shape at the option of the workman.

Plant and Apparatus Required.—The plant and apparatus necessary to effect all ordinary repairs, or to perform the operations of cutting and boring, may be of the simplest description, and where an ordinary low-tension electric installation is in operation practically everything necessary is in stock. The dynamo should be of compound-wound type, having a capacity of 250 to 350 amperes at a pressure of 70 to 90, preferably about 85, volts. The cable from the positive terminal of the dynamo should be carried direct to the welding table or to the article to be worked. The negative cable should be carried from the dynamo to the regulating resistance, and thence to the carbon-holder, which the workman holds. The face and eyes of the workman must in all cases be protected, that portion of the protector covering the eyes being of coloured glass, preferably in three separate thicknesses, and composed of ruby pieces.

Necessary Precautions to Ensure Sound Welds.—The carbons used should be uncoppered and of one uniform quality, sound and hard, and have a metallic ring when struck, and must burn with little or no dust deposits, otherwise the finely-divided carbon deposited on the weld may be absorbed by the metal, which will thereby be rendered brittle. When building up, the metal introduced into the weld should be as nearly as possible or the same composition as that of the article to which it is welded, and the workman should remove the slag formed on the surface of the weld from each layer added before commencing to add another one. In cases where the part to be built up projects above the neighbouring surface—as, for instance, a wheel tooth—each layer of material added should be retained in position and prevented from flowing away while in a molten state, and this is best done—previous to the addition of each layer—by forming a ridge of finely-ground gannister round the circumference of the layer to be added. When the metal in the vicinity of the arc has been under the action of the arc for a short space of time, the heat gradually extends by conduction to the metal in the neighbourhood of the part operated upon, whereby the resistance of the metal to the passage of the current is increased, and admits of a longer arc being obtained than under conditions where the metal in the vicinity of the part operated upon is not so heated. The workman should always endeavour to obtain these conditions of heating of the surrounding metal, and to finish off each layer under the action of a long and steady arc so as to ensure the gradual solidification of the metal added, and its subsequent annealing by the gradual radiation of the heat from the part operated upon, when the carbon is eventually withdrawn and the arc broken. In all cases where it is possible to do so each layer of new material added should be hammered immediately after the carbon is withdrawn and the arc broken, and where this is not possible the withdrawal of the carbon and breaking of the arc should be gradual.

The Deflected Arc System.

The field covered by the Benardos system just described, whilst being considerable, left something to be wished; for instance, repeated attempts have been made to make electric seam and lap welds, and to carry on operations of brazing and soldering. With the Benardos system this is impossible; it was therefore necessary to find other means than those hitherto employed. The heat of the electric arc is probably over 3,000deg. C., and with the Benardos system is concentrated on a small area. Simply because of the fact that the arc can only be formed between the carbon and the metal to be worked, all attempts to reduce the heat, and, secondly, to spread it over a larger surface, have failed. Dr. Zerener, of Berlin, saw the difficulty, and he has devised apparatus which is supplying the want hitherto felt in this last-named process. The dynamo mains are connected (through the usual regulating resistances) direct to two terminals very much after the fashion of an ordinary arc lamp with its regulating resistance in series. The current passes through the lamp connections to a carbon on the positive leg, jumps the air space, and returns to the dynamo through a negative carbon again, precisely similar to the arc lamp; but on each side of lamp an electromagnet is arranged which is energised by a portion of the main current being shunted through it, and in exact proportion to the current absorbed or rather required by the carbons. Thus, the moment current is switched on, a strong magnetic field is formed in which the arc is burning. This magnetic field effects the arc, and draws or spreads out the flame, and the extent of this drawing out can be adjusted at will. The members will at once note the difference between the two processes: in the latter, the welding apparatus is self-contained, and the article to be welded is not in any way in elec-

Digitized by Google

trical connection with the dynamo, and the lamp may be raised or lowered, thus regulating the temperature of the heated article. These lamps are made in various sizes, the smallest one requiring only 27 amperes at 70 volts, or, roughly, 3 h.p.; it is capable of making 2,000 bicycle brazes in a week of 54 hours, and manipulated by one man. Up to a pressure of 75 amperes the lamps are held by the workman, over that current the apparatus is too heavy, and must be suspended over the work. The small lamps are adjusted by hand, the larger ones are automatic, and feed themselves in the manner of an arc lamp. The regulating resistance and other accessories are in every way similar to those used in the Benardos welding process.

Brazing.—A large variety of work has been accomplished in brazing copper tubes and flanges, copper to steel, brass to iron. Copper and zinc stampings as thin as 1-32in. have been successfully brazed without any running of the metal at junctions. Steel plate up to ¼in. thick, in the shape of barrels for carrying oil, petroleum, etc., water-cisterns, buckets, and other similar articles are electric brazed. Perhaps the most extensive application of electric brazing has been found in the cycle industry, where the work is most economically performed, from the fact that the plant can be run at practically normal load through the working hours.

Welding.—The chief application in welding up to the present time has been in seam welds on sheets or plates up to ½in. thick. Four boilers have recently been completed as a test for hot-water circulation for an American firm. The boilers were made of No. 14 gauge mild steel, they are 16in. in diameter, and 5ft. long; after the sheet has been formed into cylindrical shape, the longitudinal weld is made, the ends of the boiler are convex, and are welded to the shell. With a temporary appliance one boiler was completed in 55 minutes—viz., the longitudinal seam and two end welds; the current required was 230 amperes at 75 volts, and one man did the work. Steel pipes have been very successfully seam-welded for a length of about 10ft., having a diameter of 13in. and thickness of ¼in. A sample was tested with the following result: "Sample tested up to 450lb. per square inch, and, so far, appears perfect." Pipes varying from 1-16in. to ½in. in diameter have been made with equally good results. The seams are drawn up close, small pieces of mild steel are laid over the junction, and the process of welding goes on for some 6in., and when the fusion is perfect the joint is hammered. The rate of working is about the same in all thicknesses—viz,, about 1ft. in seven minutes. The current used varies, of course, with the thickness of the metal. A large plant has recently been erected in Hamburg for the manufacture of steel barrels, the capacity being equal to 100 barrels per week.

In conclusion, the writer begs to point out that this system of electric arc welding is not proposed as a substitute in all cases for the ordinary methods of welding now in use; nor is it proposed as a substitute for riveting in high-pressurse boilers, but rather as an additional method, capable of very extensive application, under conditions where the ordinary methods of welding are inapplicable. The simplicity of the process and the portability of the plant, combined with the large field where such a system would be most valuable, are certainly good reasons for a more extended use. It is perhaps impossible to conceive a more useful application for electric arc welding than the general requirements of a large colliery. All kinds of repairs can be made, as shown in the examples recorded in this paper. The apparatus is always available, and in many cases, there can be little doubt, would effect considerable saving in the promptness with which these repairs would be effected. It may perhaps be as well to again affirm the fact that welding and lighting can readily be arranged from the same generating plant.

THE TELEPHONE QUESTION.*

BY ALFRED R. BENNETT, M.I.E.E.

(Concluded from page 206.)

The want of agreement between partners is generally accepted as a proof of the weakness of their case. In this connection it is noteworthy that the evidence given by the Post Office and by the National Telephone Company before the late Select Committee did not always agree, and sometimes, even on essential points, was contradictory. The Post Office witnesses, in order to support their exaggerated estimates and to justify the high charges of the Department, laboured to convince the committee that as telephone exchanges grow, complications of the wires and switching apparatus increase out of all proportion to the additional number of subscribers, and that the cost of the switching apparatus especially increases in a ratio which, if it were true, would justify Mr. Arnold Morley's statement that the telephone can never be more than a luxury for the rich, since the growth of the exchange would soon render the cost of its extension prohibitive. If the committee had heard independent witnesses it would have been demonstrated that the Post Office figures are not justified by experience, which shows that the ratio of increase of cost in a properly laid out exchange is not notably out of proportion to the increase of subscribers' rentals. Mr. Forbes, speaking for the National Telephone Company, practically demolished this part of the Post Office evidence as he told the committee in explaining why the rate in Lancashire, which was originally £20 per annum, had been reduced, said that while the exchanges at Manchester, Warrington, Liverpool, etc., were in their infancy it was necessary to have a high rate, but that they grew rapidly and to such an extent that the directors saw their way to make a reduction to £15 per annum, and subsequently, after a further increase in the number of subscribers, to £10. According to the Post Office evidence, rates under such circumstances ought to have been increased, whereas the company adopted precisely the opposite plan and reduced them by 50 per cent.

Before the same committee the National Company deprecated competition as inimical to the interests of subscribers and the public generally, but then its preaching on this occasion differed widely from what has been its practice. For instance, Messrs. Tasker and Co. established their exchange in Sheffield, and held the town for many years without a rival; but in 1887, when Tasker's exchange was already a large one, the National Telephone Company commenced business in Sheffield, cut down rates to £5 for any distance, and notwithstanding its professions of solicitude for the public interest, deliberately inaugurated competition of the most active kind within the same area. That competition ultimately resulted in the acquisition of Tasker's exchange by the National Telephone Company, but Tasker, in giving up his business, made stipulations which have secured to the Sheffield public rates from that company (see my paper on "Municipal Telephony," read before the Northern Society of Electrical Engineers, November 11, 1895) which are lower than those enjoyed by any other town of corresponding importance. The Post Office opened an exchange in Cumberland; some months later the National Telephone Company commenced a competing system, and ultimately blotted out that of the Post Office. In Leicester, the Post Office opened an exchange, and connected to it nearly 200 subscribers; years afterwards the National Telephone Company commenced competition in Leicester at lower rates, and has now so reduced the Post Office exchange that only a remnant of some 20 subscribers is left to it. Other instances could be adduced in which the National Company has been the aggressor, and it would be interesting to learn how this fact can be reconciled with its present objection to competition. Is it not probable that this solicitude for the public interest has its origin in the fact that owing to the existence of its present monopoly the National Telephone Company must necessarily in the future be the attacked and not the attacker?

APPENDIX.

OPINIONS ON THE TELEPHONE QUESTION, EXPRESSED BY MR. F. E. BAINES, C.B.*

Extracted from his recent book, "On the Track of the Mail Coach" (Bentley and Co.).

The telephone, which I regret to see a statesman of weight regards as a luxury of the rich, is, from my point of view, a necessity of the poor. The public have little idea of its enormous social and commercial importance to all classes. Not in my opinion alone, but in that of persons who can speak authoritatively on the subject, is a telephonic exchange needed in every town and in every considerable village. A telephone made without the middleman costs but a few shillings; it need be no more expensive than a Waterbury watch. The annual cost of keeping up a mile of telephone wire ranges at the most from 25s. to 45s., and even allowing for the doubling of the wire, £3 would probably be an outside average. Perhaps even £2 a year per wire would in practice cover everything.

The prime necessity of a liberal extension of the telephone in the direction indicated I mention here, not as an original suggestion of my own. . . . It has been urged in a general way more than once by a member of Parliament who has for some years past directed public attention to details of postal economy, and it has been advocated in the public Press, and before a Select Committee of the House of Commons.

There would seem to be a general consensus of opinion that a liberal use of the telephone in rural districts would be of immense advantage to the State. How the telephone should be provided, by whom and under what conditions, may be matter of opinion, and is, in any case, of secondary importance. The primary object should be, by hook or by crook, to bring the telephone within the reach

* Late her Majesty's Inspector-General of Mails, and formerly Chief Controller of the Post Office Telegraphs; author of "Forty Years at the Post Office." Mr. Baines was first to formulate proposals for the acquisition of the telegraphs by the State.

of everyone. But no insuperable difficulty occurs to me in the working out of such a scheme as is presented in this chapter by the Post Office in conjunction with any telephone company. A company would contract for, supply, and maintain telephone lines either on its own responsibility or as the agent of the Department, and to the advantage of both. Where the annual charge would be less than £5 purely local communications are in view. Where it would possibly be more than £5, communication through two exchanges is contemplated. In other words, telephonic communication from one part of a village to another part of it, or, similarly, from one part of a country town to another part of the same town, can be very cheaply provided and maintained. When a renter in the village requires the means of telephoning to a renter in a neighbouring town, and two exchanges are put in action, the cost is necessarily somewhat enhanced.

In time rich and populous England will learn a useful lesson from small and thinly-inhabited states—from Sweden and from Switzerland, from Denmark, and elsewhere, for already in Sweden the Government is about to combine the telephone with the State telegraph system. In that country everybody is stated to be "on the telephone." This is the key of the whole situation. England, whether urban or rural, would be a changed place—half its troubles would vanish—if that development were given to the telephone of which it is capable.

INSTITUTION OF ELECTRICAL ENGINEERS, Feb. 27.

Dr. Hopkinson (President) in the chair.

At last night's meeting of the Institution the following candidates were balloted for:

Members.—Robert Stuart Hampson, Manchester, Sheffield, and Lincolnshire Railway Co., Guide Bridge, Manchester; Walter Osmond Rooper, Mill-street, Stafford; Major R. M. Ruck, R E., The Horse Guards, Whitehall, S.W.; David C. Smith, Oak-avenue, Elsternwick, Melbourne, Australia.

Associates.—John E. Addyman, 13, Sterne-street, Shepherd's Bush, W.; R. Stewart Bain, 25A, Cockspur-street, S.W.; Lawrence Birks, University College, London, W.C.; Walter Henry Cooke, 1, Bevois-terrace, Southampton; Arthur Thomas Cooper, Corporation Electricity Works, Blackpool; Oswald L. Falconar, Monkseaton, Newcastle-on-Tyne; Frederic Fowkes, Hawkstead, Ambleside; John George Freeman, 25A, Cockspur-street, S.W.; Sam. Handford, Ford House, Prestbury, near Macclesfield; Richard Hamerton Hayne, care of F. A. Glover and Co., Woolcomber-street, Dover; Charles Keeble, the Palatine Insurance Company, 101, Cheapside, E C.; Sidney Edward Linsell, 10, Corporation-street, Manchester; Arthur Richard Peart, Hanover Lodge, Chiswick; John Pilling, 90, John Brown-street, Bolton; Percy Speedy, 55, Victoria-street, S.W.; William Arthur Stevens, Maidstone, Kent; Walter Jeffrey Targett, 25A, Cockspur-street, S.W.; William A. Walton, London-road, Gloucester.

Students.—Leslie H. Andrews, 29, Lady Somerset-road, Highgate, N.; Ernest William Bache, Churchill House, West Bromwich; C. D. Braddon, Arc Works, Chelmsford: Arthur Daniel Crowther, Wardwick, Derby; Fred. Leslie Cruikshanks, 813, High-road, Tottenham, N.; Arthur Dangerfield, 292, High Holborn, W.C.; Charles W. Eden, 16, Peel-street, Nottingham; Allan Edgar Eyears, 34, Osborne-terrace, Westcombe Park, S.E.; William Ernest Few, Faraday House, Charing Cross-road, W.C.; Philip Henry Gibbs, 39, Lytton-road, Leytonstone, Essex; Ernest Joseph Greensmith, 49, Heathcote-street, Nottingham; H. C. Gridley, Moira House, Hampton Wick; William P. L. Harrison, Beaumond Cross, Newark-on-Trent; James Fitz-James McKean, Lanagh House, Castleblaney; Alfred Mitchell-Withers, 7, Woburn-place, W.C.; Austin H. Peake, Codnor, near Derby; Ernest Henry Rogers, Oakley Manor, Shrewsbury; Sydney John Roseblade, Glendale, Hamilton Drive, Nottingham; Charles B. H. Stalvies, Trent Bank, Wilford, Nottingham; Edward Ernest Tasker, 3, Cumberland-terrace, Lloyd square, W.C.; Robert Tervet, 54, Penshurst-road, South Hackney, N.E.; Thomas Julian Tolmé, 4, Salisbury-road, Wimbledon, S.W.; James Welford, 4, Beech-avenue, Sherwood Rise, Nottingham; F. H. Wilson, University College, Nottingham.

The **Secretary** announced that since the last meeting he had received from Mr. G. G. Ward, to be presented to the Institution, a very beautiful photograph of a picture lately presented to the New York Chamber of Commerce of the projectors of the Atlantic Cable.

On the proposition of the **Chairman**, a vote of thanks was accorded Mr. Ward for his gift.

The photograph, which was handsomely framed, was exhibited in the room.

The **Chairman** said, before they resumed the discussion on the papers by Mr. Bathurst and Mr. Sam. Mavor, he wished to state that it was important that they should get forward with their business that evening so that, at all events, they might get an abstract of Mr. Addenbrooke's paper dealt with. Therefore, he suggested that the speeches should be limited to five minutes. This was agreed to.

Mr. Binswanger dealt with the subject of the papers from the point of view held by the manufacturers. The question whether this or that system of wiring should be adopted for any installation was a question to be decided by the contractor. They, the manufacturers, had to find out what demand was likely to arise. Many contractors held the opinion that wiring in wood casing must some day or other be superseded. The material required for wood casing had had an enormous sale during the last 20 years, and at the present moment the cost was very low. To compare the cost of new installations proposed under the new methods with that of the old methods would, to his mind, be very unfair to the new methods. He could confidently predict that if either of the new systems proposed could have a fraction of the run that the old system had, the cost of the new one would compare very favourably with it. He urged simplicity of construction; they should use as few parts as possible in an installation. Why should they have to make different alternating-current motors, different alternating meters, and different alternating arc lamps simply because so many different frequencies existed in alternating stations? He concluded by suggesting that these questions should be well considered, and that a committee might be appointed by the Institution to give manufacturers some standard which he thought every manufacturer in England would be glad to adopt.

Mr. Boot said few of the members realised the enormity of the question at issue. So very much depended on wiring. It was no use their generating electricity if they could not use it in some more simple manner than was at present the case. Unless they adopted some system by which they could reduce everything to its lowest cost, he did not think they would do any good by adopting any fresh system. He, too, strongly urged simplicity of construction, which, he said, added to the merits of electricity. The great cost was in the labour, which they must reduce, and they must make the systems of wiring so simple that any ordinary man of intelligence could use them and put them up. His experience of concentric wiring was that it was not so cheap as regarded fittings as Mr. Mavor stated.
